REMITTANCES should be made payable to the Publisher only, and should be made by Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We invite contributions of value to the profession, and if published originally in THE REPORTER such will be paid for at liberal rates, or a limited number of copies of THE REPORTER will be supplied, as the author may elect. Hereafter where reprints are desired writers are requested to make a note of that fact on the first page of the MS., but must order reprints directly from the publisher, who will supply the same at cost rates. Contributors should inclose stamps for postage, that the articles may be returned if not found available.

EDITORIAL.

MEDICALLY PURE IN ART.

In another column we reprint a letter to the editor of the *Medical Record*, from an honored member of the American medical profession, anent the subject "Scientific versus Obscene Medical Literature."

Everything considered, the New York Academy of Medicine is, perhaps, the most influential and aggressive medical organization in this country. It has not hesitated to exert its influence in public affairs when the opinions of medical science were important for public good. No further explanation for the medical supremacy of New York is necessary, when there exists a profession whose representative men devote time and thought to the enlargement of public weal rather than to the curtailment of private competition. Whatever may be the local differences, and however intense may be individual or factional feelings, the profession of that city is united for medical New York. It furnishes a significant lesson for other aspiring—or expiring medical centers, Philadelphia not excluded; and for selfish considerations if for nothing higher. It shows the unwisdom of becoming rapt in a too utterly soulful contemplation of the picturesquely moss-bedecked monuments of what has been, and indulging in an æsthetic languor superinduced by the exhalations of a ponderous dignity, in existence purely subjective. The mountain does not seek Mohamet in the dawn of the 20th century.

Dr. Jacobi's proposed measure may not be ideal but it is practical. It is an effort to advance and THE REPORTER gives it cordial approval.

A closely allied evil, although operating more within professional limits, may be denominated "Scientific versus Obscene Medical Illustration"—a distinction as well defined in pictures as in letter-press.

It is needless to urge the utility, and even the necessity of illustration in medical literature. At the very best, medicine does not afford a field rich in subjects suitable for "high art" in its general application.

Medical illustrations may be classified, according to the purposes of their produc-

tion, into three groups. Those familiar with medical literature can promptly refer to its proper category every illustration presented, without a detailed description of the groups more than may be inferred from a candid answer to the question, Why this illustration?

The first group, which may be said to include the major part of medical art, is presented purely to aid in accurately comprehending the meaning of the context. Such illustrations often are as necessary to the proper elucidation of the subject-matter as are figures to a successful demonstration of problems in geometry. This is the legitimate function of art in medical literature, and the more accurately and elegantly it performs its office, the greater becomes its value. As might be expected, this group contains almost all diagrams and conventional figures, colored plates, and the greater portion of hand-wrought illustration. Contrary to the popular impression, a large share of process-reproductions of photographs from life are excluded from this first group, and for reasons obvious when the mechanical difficulties to be overcome are taken into consideration.

In the second group will be found such illustrations as are made to sell a book, or perhaps to gratify some little personal vanity. Instances of the seductive representations of canvassers who enlarge upon the magnificent pictorial display of the forth-coming work and discourse learnedly concerning "half-tones" and "photo-gravures" etc., etc., while meditating a raid on the doctor's pocket-book—such instances have become every day incidents in the lives of most medical men, especially distasteful to those who have subscribed in haste to repent at leisure. Not infrequently it happens that illustrations of this class are not only useless but are obscene—that is to say they rank very high as specimens of "pure (!) art". To this class belong also those illustrations which are sometimes used to enlighten the darkened understanding of medical men as to the applications of office-tables or other paraphernalia devised for the peculiar needs of medical practitioners. We have never yet seen a picture of this class which the wildest stretch of the imagination could regard as artistic, while in most cases it would be base flattery to call them vulgar. As to the protraits which exist mainly for the gratification of some little personal vanity and the desire to preserve to posterity the counterfeit presentment of one ambitious for fame, such pictures are generally as harmless as they are useless, but occasionally they bring retribution out of all proportion to the fault committed. A recent instance of "vaulting ambition, which o'erleaps itself, and falls on the other," the ambitious one, who, "only reaps from the hopes which around him he sows, a harvest of barren regrets," is found in the case of a brilliant young gynecologist whose features will be remembered by the readers of the twentieth century because of an incongruous association of ideas, no matter what visions of power and excellence the mention of his name may call up. This unfortunate individual had the imprudence, in some artistic production peculiar to his special work, to permit the foreground of some destinctive illustrations to be filled with most excellent photographs of himself, at the same time the only other striking feature in the group being to say the least, embarassing. He can derive no comfort from the situation, for the portraits are practically useless for any other purpose.

For the third group of illustrations occurring in medical so-called literature, but one reason may be assigned—as our Southern friends might express it, "pure, low-down on'riness." This style of art will ofttimes be found interleaving the advertising pages of some medical periodicals, in other respects not necessarily disreputable. For these illustrations the

very best that may be said is that they are obscene, and that under any circumstances they are unpardonably out of place in the pages of a medical journal, no matter how refined artistically or how pure in art aspiration such a journal may be. Undoubtedly these publications are under the ban of federal law even when construed most liberally. Their suppression would benefit medical science and medical literature would never notice their disappearance.

"SCIENTIFIC VERSUS OBSCENE MEDICAL LITERATURE."

To the Editor of the Medical Record:

SIR—Under the above heading you published in your late number an editorial, which presumes to believe that for some reason or other, medical literature could be excluded from its present mail privileges if obscene literature were, through the passing of a strict and special law, prevented from enjoying them.

"Permit me to copy the wording of the bill proposed by me for the consideration and acceptance of the Medical Society of the County of New York, and of the New York Academy of Medicine. They were as follows:

"'Be it enacted, etc.,

"'That medical books, pamphlets and circulars, the contents of which are of a character not proper for general and indiscriminate perusal or circulation, shall not be admitted to nor transmitted through the mails unless enclosed in sealed envelopes or wrappers, and prepaid at letter rates of postage, *or unless addressed for delivery to or in care of physicians, surgeons, medical schools or colleges, or students in such schools or colleges, or to dealers in medical publications, and directed to them as such.'*

"It appears, Mr. Editor, you overlooked the last clause of the proposed bill altogether. If it were passed no medical journal or book would be interfered with, indeed, medical men and students, schools and dealers, would still enjoy the advantage of receiving, free of cost, their advertisements of 'Dr. W., female specialist,' of the 'Power Wafers,' of the 'Constitutional Tonic Wafers,' of the 'Way of Escape,' etc. It is true our boys and girls would not so easily be reached by the miscreants, as hitherto. Nor would they be told where the office can be found, and when, and at what price, where their bodies may be defiled, and their souls contaminated. A prominent postmaster in the United States received the following note from a father: 'The enclosed disgusting pamphlet was received through the mails by my son (fifteen years of age) yesterday. I do not know whether it is a violation of the postal regulations to use the mails for transmission of matter of this kind, but I consider it decidedly indecent and demoralizing.' This note was accompanied by a glaring circular describing 'how the celebrated Sultan's or Turkish wafers came to be introduced to Americans.' It was the same postmaster who suggested to me the bill as printed above. It is at present in the hands of the Hon. E. J. Dunphy, a representative of this city, who is a member of the House Committee on Post Offices and Post Roads. I do not say it is the best possible bill, but it is a better one and more efficient than you supposed it to be in your editorial of last week, and does not in the least interfere, as you will now admit, with the unhampered circulation of *medical* journals, magazines, pamphlets, or books. It will, when passed, protect to a certain degree against the filthy sheets disseminated by quacks as privileged mail matter.

"You, Mr. Editor, and your colleagues of the medical press, have great facilities in impressing and directing the conscience of the medical profession and the public at large. As that is so, your duties and responsibilities are just as great, and I fully believe you will benefit the community by again studying, and then recommending (amended, perhaps), and urging upon the representatives of the people, the bill introduced by me at the suggestion of a gentleman who had great opportunities to learn of the vast amount of obscene

literature distributed over the country, under the protection of the law of the land." Very sincerely yours,

February 26, 1895. A. JACOBI, M.D.

["After this explanation we not only agree perfectly with our distinguished correspondent, but give the measure our heartiest endorsement.—ED. MED. REC."]

ABSTRACTS.

A CASE OF ANESTHESIA WITH DEATH, AND ATTEMPTED EXTORTION SUCCESSFULLY RESISTED.*

EDEN V. DELPHEY, M.D., NEW YORK.

Among the many trials, troubles, and tribulations of members of our profession, is the one wherein some designing and unscrupulous person thinks he sees a short road to wealth by mulcting the family physician in a suit for damages.

Having recently, with a brother practitioner, been the victim of such an attempt, having together successfully resisted the attempts at extortion in a court of law, and being informed that no case of this kind and character has ever occurred in this State, we think it best that a statement of the facts be placed on record.

On February 13, 1892, Dr. A. H. Goelet of this city asked me to go with him to see a patient and perhaps to give an anesthetic for the purpose of amputating a gangrenous finger. On arriving at the patient's residence and after removing the dressing we agreed that it would be inopportune to operate at that time. On the 19th of March, following, while calling at the doctor's office, the patient came in and together we discussed the operation which was set for the following day, on which day, the 20th, we went to the patient's residence, began to give the anesthetic, and the patient died. Inasmuch as the facts and circumstances relating to the administration of the anesthetic, the attempts at resuscitation, etc., were brought out in the suit for damages, and are clearly and concisely stated in the hypothetical question, attorney's address, and judge's charge, they will be recounted later in that manner.

A few days after this unfortunate occurrence, we were each visited by a representative of a so-called "Society for Protection from Personal Injury," who stated that a suit was about to be begun and tried to induce us to compromise the case, but knowing we had done no wrong, regretting the misfortune as much as any one, and having the welfare of other members of the profession at heart as well as our own, we declined to do so. Some little time later we were again visited by another representative, who was very arrogant and abusive in his endeavor to extort money.

The trial, after many days, finally began in the Supreme Court before judge Truax, on Tuesday, April 24, 1894, and ended Friday, April 27, 1894, the jury bringing in a verdict in our favor.

The experts for the defense were: Drs. T. Gaillard Thomas, William T. Bull, Robert Abbe, J. West Roosevelt, Herman J. Boldt, Edwin B. Cragin and Ferd C. Valentine, and the hypothetical question was as follows:

HYPOTHETICAL QUESTION.

Q. Assume that a patient of about 52 or 53 years of age had gotten a splinter in the forefinger of his right hand; that it affected the bone, that gangrene set in, that he had septic symptoms, that he went to a physician's office one evening to have his hand dressed, and on examining it, the physician found that the bone could be taken out without giving an anesthetic, but he said he would not be able to bear the pain of it without an anesthetic; that the physician made an examina-

*Read before the 11th Annual Meeting of the New York State Medical Association, October 9th, 1894.—From the Amer. M. So Bul.

tion of his heart, his lungs, and his urine, and found that they were normal; that the physician attended with an assistant who was accustomed to give anesthetics to perform an operation of amputating the diseased finger; that while the physician was preparing his instruments the patient remarked: "Doctor, you are not going to give me chloroform, are you?" and the physician told him he would give him chloroform only in the beginning, as he would need less of the anesthetic; that the patient said nothing more; that the assistant also made an examination of his heart and lungs and was present and watched the physician when he made an examination of the patient's urine and coincided with his opinion of the results found by such examination, and that urine contained neither albumin nor sugar, and was normal. That the assistant asked the physician if he should commence with chloroform, and the physician said "Yes," and that then the patient was lying on the bed, partially undressed, prepared for the operation; that chloroform was administered by means of an Esmarch inhaler, and that the chloroform was dropped, drop by drop, on the inhaler from above; that about a half and not more than a fluid dram was used; that during the inhalation of the chloroform the patient began to resist, and threw his arms about the bed; that the physician sat on the side of the bed and took hold of the wrist of the sore hand so he would not injure it; when he became quiet the physician turned away to prepare his instruments, and while doing so he heard the patient breathing stertorously, that chloroform was laid aside for about one to two minutes until there were signs of returning consciousness and the stertorous breathing had changed to quiet and normal breathing. That either was then substituted for chloroform, and administered by means of a cone made of folding paper and towel, that shortly after the assistant asked the physician to help him, saying that the patient had stopped breathing. That the physician went quickly to the opposite side of the bed, and with the assistance of another person in the room, elevated the patient's feet and suspended his head and shoulders over the side of the bed, so that the assistant could make efforts at artificial respiration. That the assistant worked on the patient to produce artificial respiration, by the assistant grasping him by the elbows, pressing them forcibly against the chest, then extending them over the head, pretty well back, and repeating this performance about twenty times a minute for about half an hour, but without avail, that only after the heart had ceased to beat were efforts to resuscitate discontinued.

Now, in your opinion, did or did not the physician and his attendant or assistant use the proper and usual course adopted by physicians and surgeons in such cases?

A. Yes.

Assuming the same state of facts, did or did not the physician and his attendant or assistant practice and observe the usual methods generally and ordinarily adopted by physicians and surgeons in such cases?

A. Yes.

Assuming the same state of facts, did or did not the physician and his attendant or assistant practice and observe the usual methods generally and ordinarily adopted by physicians and surgeons skilled in performing such operations?

A. Yes.

Assuming the same state of facts, did or did not the physician and his attendant or assistant practice and use the care and skill ordinarily used and employed by skilled physicians and surgeons in administering chloroform or either?

A. Yes.

Assuming the same state of facts, in your opinion, had or had not the physicians committed malpractice?

A. Certainly not.

The attorney for the defense was Albert C. Aubery of this city, and after thanking the judge for his fair decisions and the jury for their patient attention, reminding them that His Honor was judge of the law and they were sole judge of the facts, and that their responsibility was no light one, as on their decision hung the future professional hopes and prosperity of the defendants, he said:

Now, gentlemen, what is this action? By whom is it brought? Against whom is it brought? And what will be the result of your decision? These are questions to which I propose to call your attention, requesting the same degree of attention on your part to what I may say that you have already given to this case.

This action, gentlemen, is to recover

the sum of $5,000 from the defendants by the plaintiff for alleged malpractice.

The plaintiff is the widow and administratrix of M. L., deceased. She sues as such administratix, under the statute of the State of New York, claiming that amount of damages—mark you, gentlemen, damages!—for wrongfully causing the death of her husband. She claims that the defendants administered to her husband chloroform, a deadly anesthetic, in their capacity and occupation as physicians and surgeons, so negligently and unskillfully as to cause his death, thus depriving her and her children of their only support. She also claims that chloroform was administered to her husband by the defendants contrary to her husband's expressed request, and contrary to her request and that of their children. The husband of this plaintiff was afflicted with gangrene of the forefinger of his right hand. The finger was to be amputated. The defendants were employed to perform the operation. They deny all charges of negligence, or of other improper conduct. I think, gentlemen, you will agree with me that I have made a fair statement of the case, and by whom it is brought.

As to the question against whom it is brought, you, gentlemen of the jury, have seen them here. Ever since this case has been on trial—now its fourth day—the defendants have been in court, their future professional reputation dependent upon your decision. They fear not the result, for they conscientiously feel that there is not a man on this jury who will not decide this case under the solemn oath he took, when he was sworn as a juror, to render a true verdict upon the evidence.

After referring to the positions of the defendants in the community, he continued:

This suit, gentleman, is not brought against a branch or limb of the medical and surgical profession, but against the root and tree of that honored profession. It is a blow struck at its very foundation. A blow which, if you shall hold is well aimed by your verdict for the plaintiff in any sum, however small, means a deadly blow to that profession. But I believe better things of you. I have in you full confidence that you will render a verdict which will send both of these defendants back to the bosom of their respective families, now anxiously waiting their return, to gladden not only their hearts, but one which will be flashed over the electric wires, binding State to State as one common brotherhood, to every medical society in this country, that these defendants are not guilty of malpractice; that they are not malpractitioners.

What profession, gentlemen, is more honored than the medical? I know of none. The physician comes nearer to the bosom of your family and life than any other of the learned professions. While the minister and the lawyer in turn have their arduous work and duties, yet the medical profession is the one you look to so that you may have a clear head and perfectly healthy body for your daily labors. It is he who holds the secrets of your life. Your physician, in order to carefully administer to your every want and need in time of sickness, should know your whole system and life from the cradle. It is to him you reveal your whole life and deeds so he may judge how properly to relieve your sufferings so you may attend to your daily duties; and in your last hours on earth, he is often found to be the best comforter and sympathizer with those whom you may leave to mourn. What profession is more noble?

Gentlemen, there is more at interest here than if this were an action for debt. These defendants are not in debt to this plaintiff. They do not owe her a cent, and although this suit is one to recover money damages, the effect of a judgment for any sum against these defendants is far-reaching and significant. It means that they have been careless, negligent, unskillful, and untrustworthy in their professional conduct. This is the charge. Their professional reputation is attacked! This is a suit for malpractice, gentlemen; do not forget that! Now, what is malpractice? Let us see if the charge has been established, and if these defendants are malpractitioners. Malpractice is an improper discharge of professional duties, either through want of skill or negligence. In other words, it is negligence. That is a fair definition. Being an action for malpractice, it is one in tort, as we lawyers say. Now, the medical man holds himself out to the public, that he possesses the ordinary skill requisite for reasonable success, and that he will attend to the case put in his charge with due care. Hence, negligence in the medical man is a viola-

tion of the obligation that he impliedly enters into when he accepts charge of a patient, which obligation enjoins care and caution in what he does and what he omits to do.

He then explained that the burden of proof rested with the plaintiff, and commenting on the evidence and the results of the autopsy, which were "pulmonary œdema, pachymeningitis, old adhesion of lung on left side, kidneys show some changes, gangrene of the first finger of the right hand," said:

You will remember that the plaintiff's case was hanging by a hair, and it was only because I saw the trial was about to terminate by the withdrawal of a juror, resulting in a mis-trial, that I consented, in order that these defendants should have an opportunity to be heard, to admit that if Dr. Walsh, who had made the autopsy, and who is at present on the high seas, was in court, he would testify that the autopsy disclosed just what I have stated to you.

* * * * * * On behalf of the plaintiff, a Dr. —— was called to give expert evidence. He said he resided at ——avenue, in this city. He said he graduated from the University at Vienna; that he came to this country in 1875, and graduated in 1884 from —— College, in Chicago. In answer to a question of the plaintiff's counsel, he testified that no conscientious physician would administer chloroform to a patient having incipient disease of the kidneys. This was the counsel's climax. The height of this case had then been reached. The witness submitted most unwillingly to cross-examination. You will remember how I asked him question after question as to what effect chloroform would have upon the human system. Many books of standard medical authority —books which he was compelled to admit were standard authorities, whether he had ever seen them or not—were read to him, paragraph after paragraph, wherein all the authors had written and asserted exactly the opposite to what he had testified to. The only way in which he could crawl from the ridiculous position which he had assumed, was to say, "I don't agree with the author." He put himself up as authority against them all. Yet he had to admit, although he had held the position of a Coroner of some obscure place out in the Western part of this country, that he has had deaths in his practice while he administered anesthetics. What could be his defense in case a suit for malpractice should be brought against him, when all the standard medical authorities would be read in evidence, as against the method he had adopted or the remedies he had used? I confess I do not know. I fear he would have to throw himself on the mercy of his accusers, and beg. Contrast him, as a witness, and his testimony, with all the standard medical authorities here produced; contrast him and his testimony with the high character and reputation, city, State, and national, of Drs. T. Gaillard Thomas, William T. Bull, Robert Abbe, J. West Roosevelt, Herman J. Boldt, Edwin B. Cragin, and Ferd. C. Valentine, called to the witness-stand by the defendants—witnesses whose very words, thoughts, and advice are sought after by the learned of the medical profession. What did those eminent medical college instructors and hospital surgeons say? You, gentlemen, have heard how they have ridiculed him. Not one agreed with him—not one. Some simply said "No," when asked if they agreed with him; others said, "It was absurd." I challenge the plaintiff's counsel to produce another man of any medical knowledge who will testify that he agrees with him. He said no conscientious physician would give chloroform to a patient who had any kidney disease. The authorities read to you and the witness said, "Do not give ether." Would you, or any reputable physician, believe —— and give ether, when all the authorities tell you in plain words not to give ether, but affirmatively say, give chloroform? I will admit doctors do not always agree. It is not natural that they should. Some physicians will give chloroform in any case. Some will give ether in any case. The evidence has demonstrated that; but not a single expert witness testified that he should not give chloroform when the patient had any kidney disease. I think I can fairly dismiss —— as a witness in whose testimony you can place no degree of confidence or credit.

Now, gentlemen, what more did those eminent physicians and surgeons—men of national reputation—testify to? You will remember the long, hypothetical statement reciting all the facts proved in the case and the questions which followed it. All

the witnesses—yes, all, not a difference between any one—testified that the defendants were not malpractitioners, that they followed the best practice, and used all the care that could be used. They followed the usual course skilled physicians and surgeons follow in such cases; that they were not negligent in their practice in any respect; that their treatment was proper in every respect; that they all approved of etherization by beginning with chloroform.

Now, gentlemen, we will turn our thoughts to the family deprived so suddenly of its head. Mr. M. L. had a gangrenous finger. The defendant, Dr. Goelet, was his family physician, and on March 20, 1892, attended to amputate the finger with Dr. Delphey, who was to administer the anesthetic. An examination of Mr. L., the patient, as you have heard testified, was made in the usual way and manner the day just prior to that set for the operation. Under the anesthetic agent, he died. The defendants deplored and greatly regretted the death. It was an accident, an unforseen and unexpected event, which no finite being had any reason to expect. The event is greatly to be regretted by all. But, gentlemen, this is not a case of charity. No one would be more liberal to aid and assist the afflicted family in case of need than their family physician. But when that trusted, competent, and skillful family physician, and his able assistant, are attacked unjustly for malpractice, and proclaimed to the world to be malpractitioners, there was no other course left them to defend themselves, their honor, their integrity, their ability, their lifelong study, their professional reputation. That is what is at stake in this action.

There is an element in this case to which I must call your attention. You have doubtless observed, gentleman, that the plaintiff's counsel, by all the pertinacity he could possibly bring to his aid, insisted that these defendants should not testify in this case in their own behalf. He based his objection to their testimony on the ground that the code relating to legal practice prevented physicians disclosing any information obtained in their professional capacity. You will remember when Dr. Goelet was called by me as a witness, the plaintiff's counsel at once stated his objection, and made a preliminary examination of the doctor, to ascertain whether the information which he obtained and was about to testify to was obtained in his professional capacity as a physician. The doctor answered that it was. Then the counsel's objection was formally stated to the court, to wit: That the doctor was not a competent witness, as the information was sacred, and he should not be permitted to testify. What was that done for, gentlemen? The evidence on the one hand had been given. Evidence had been presented that the doctors, these defendants, did and said this and that, and yet the counsel asked His Honor, presiding over the trial of this most important case, to decide that the defendants could not testify, virtually clasping and fastening over the mouth of these defendants a sold mask to prevent them from giving their version of the unfortunate accident. Oh, no, gentlemen; he was unsuccessful! His objection was promptly and justly overruled, and the proposition decided adversely to him. Then each of these defendants told in turn all that each of them had said to the deceased; what the deceased had said to them; just what they did, and how the unfortunate death of Mr. L. happened. I will not recite it to you. You have heard all the evidence, and wherever there is any difference of question of fact presented by the evidence you are to decide it. What is more reasonable than the defendants' position that an unfortunate accident had happened, for which they, in law, are not responsible?

You have heard the witnesses testify that death will happen suddenly from chloroform, and also from ether, even with the utmost care on the part of the surgeon. There is no dispute of that fact. I have shown you by evidence that all care was used by these defendants. The anesthetic was administered in a manner approved by the best medical authorities. I have demonstrated that these physicians were justified in administering the anesthetic as they did. What now remains? Your verdict in their favor. That is now asked, and justly so. I am about to leave the case of the defendants with you. The curtain of this trial is being dropped, and when submitted to you by His Honor's charge, we will await your verdict. What will that verdict be? We feel confident it will be for the defendants. Think of it

carefully, gentlemen. What will a verdict for the plaintiff mean? Let me tell you in a few words. As this is an action for damages in tort, it can be followed by an execution to be issued against the person of these defendants to incarcerate them behind prison bars. It will be remembered by every surgeon in this land, and no surgeon will dare give an anesthetic agent until an iron-bound contract has been signed by the patient, holding the surgeon blameless for all consequences. Think of it, gentlemen; a verdict for the plaintiff! One of you, who may render such a verdict in this case, may be injured in a few days. You may be seriously injured; amputation may be necessary to save your life. You are in great pain, and suffering severely; and the injured member, be it a foot, a hand, or a finger, must be amputated to save your life. Your life's blood is slowly but surely dropping away. You exclaim: "Doctor, I can't stand it any longer! Hurry and give me something to relieve the pain, and amputate!" All is ready for the operation, but your physician suddenly remembers the case of L. against Drs. Goelet and Delphey, in which the jury decided against the defendants. Then your physician tells you, "Not yet; you must wait until I can see my lawyer, and have a contract prepared for you to sign, to protect me in case of an accident of any kind." In the mean time, you lie suffering, perhaps dying. Think, gentlemen, carefully, what results a verdict for the plaintiff in this action will bring.

And now, gentlemen, I am about through. In you we have all confidence that the case is in good and careful hands. In leaving with you this case, I must call your attention to one word in the lexicon more bright than any star in the constellations. I think I can now see it standing out in your attentive and watchful eyes, and that word is that ever far-reaching and effective word, "Justice." Do justice in this case, and as the years roll on and your time comes to leave your dear ones behind you, may you never, never have any cause to regret the verdict given by you in this action. In all sincerity, in all hopefulness in the right, and that justice will prevail, I have confidence in asking you to return a verdict for the defendants.

JUDGE TRUAX'S CHARGE.

Gentlemen: This action is brought by the administratrix of M. L., deceased, to recover compensation for the death of her husband. She alleges that, on the 20th day of March, 1892, the defendants, contrary to the repeated objections and expostulations of M. L., administered chloroform in such quantities as to cause his death on that day, and that such death was due solely to the improper and unauthorized administration of chloroform carelessly and negligently given, as aforesaid, and to the want of ordinary care and skill of the defendants, and of each of them.

The defendants deny these allegations; that is, they deny administering the chloroform contrary to the repeated objections of the deceased, M. L., and they deny that the chloroform was administered in such quantities as to cause death, or that it was administered in an improper and negligent or careless manner; so that you have, I might call them, two issues to determine: First, was the chloroform administered against the objection of M. L.; and, secondly, was it administered carelessly, negligently, or unskillfully?

Now, upon these points, the plaintiff has the burden of proof; that is, she must establish from the evidence in the case that the chloroform was administered by the defendants against the objections of M. L., or that if it was so administered, it was administered carelessly and negligently, and unskillfully, before she can recover in this action. If the evidence has left your minds in such a condition that you cannot answer these questions either one way or the other, then the plaintiff has not proved her case, and your verdict should be for the defendants.

You will observe that I have submitted the case to you in two aspects. The first is, did the defendants administer chloroform contrary to the objections of the deceased, M. L., and the second was in reference to the skill with which the chloroform was administered. You are to determine from the evidence whether or not M. L. objected to the administration of the chloroform. You have heard the testimony of the plaintiff upon that point. I charge you that an objection made by Mrs. L., or by the daughter, is

not an objection that the defendants in this action were bound to give heed to, especially when you consider that Mr. L. himself was present. Their wishes do not bind the defendants in this action. I do not pretend to repeat to you the exact words that were used by Mr. L., but you may remember it was something like this: Mr. L. said: "Don't give me chloroform, Doctor;" and then he said, subsequently, about the same time: "Don't hurt the old man, Doctor."

The statement of the witnesses for the plaintiff is denied by the defendants; that is, the defendants say that Mr. L. did not give a positive command not to administer chloroform, and, therefore, I leave this question of fact to you, to be determined from the evidence in the case. But if you come to the conclusion that the deceased did, in fact, say, "Don't give me chloroform, Doctor," I leave it for you to determine whether that was meant as a command, or whether it was the expression of a wish on his part that he was not to receive chloroform, the same as the other expression, "Don't hurt the old man, Doctor," or "Don't hurt an old man." That question of fact, which you will discuss among yourselves when you reach the jury-room, is to be determined by you from the evidence.

Now, if the doctors, against the wish of Mr. L., administered to him chloroform, they became trespassers on that moment, and they are responsible for the results of their trespass. I charge you that the evidence shows that Mr. L. died, not because chloroform was administered, or because ether was administered, but that he died because some kind of an anesthetic was administered to him; and you must find from the evidenee in the case that he died because chloroform was administered to him, for you can hold the defendants in this action upon the trespess view of the case, that I have presented to you.

There is another view that I have suggested to you, and that is the one relating to the skill and care and knowledge of the defendants. The law requires that physicians and surgeons shall be skillful in their profession, and that they shall exercise reasonable and ordinary care and diligence, care and dilligence proportionate to the importance of the case in hand. Physicians, however, do not insure success; they are only bound to have the ordinary amount of knowledge possessed by the average of the profession, and they are bound to use only that degree of care and skill that the nature of the case requires; that is, if it is an important case, if they are administering a deadly drug, they are bound to be more careful than they are when they administer a comparatively harmless drug.

Now, you are to determine whether the physicians have violated this rule that I have laid down to you; whether they have, in this case, failed to exercise care and skill. If they have not, then they are liable for the consequences of their act. If they have not, they are not so liable.

You have listened attentively and patiently, I have noticed, for the last two or three days to the discussions of the physicians upon this point. You have heard references made to the condition Mr. L. was in at the time the operation was performed. The doctors have told you of the examination that they made, and they have told you what they found and what they did not find; and then you have heard the other physicians testify as to whether or not their conduct under the circumstances was or was not careful.

It is unnecessary for me to go over all this testimony, because I know that it is comparatively fresh in your minds, and that it will be freshened up when you talk among yourselves. If the physicians used due care, they are not liable, no matter what the result of their action was.

You can easily see that, if a physician at all times was to be held liable for the bad results of an operation performed by him, we would have no operations performed, or any physicians to perform them. They would not take the responsibility; but they do hold themselves out as possessing special knowledge in their profession, and do also hold themselves out as exercising care and skill. If they do exercise care and skill, as I have said to you a number of times, they cannot be held liable. If they do not, they may be held liable. It is for you to say whether these physicians have violated the rule I have laid down to you.

The plaintiff sues to recover $5,000 as compensation for the death of her husband. She is entitled to recover such sum as will represent in your minds the pecuniary loss resulting to the next of kin of M. L. from his death, not to exceed

$5000. The statute allows you to fix the damage anywhere within the limit of $5,000, and you are to determine what sum, if you come to the conclusion to find for the plaintiff, will compensate the next of kin of M. L. for the pecuniary loss occasioned to them by his death. You have heard the testimony from his wife as to his earnings, and as to his general condition. You must remember, at this particular time, he was not the well M. L. of a few weeks before, but, on the contrary, was suffering from a gangrenous affection of the finger.

I think that Dr. Thomas, in referring to that, said: "You wouldn't let the man go and die, would you?" Therefore, you must take into consideration the condition that he was in at the time that they gave him the anesthetic.

The jury rendered a verdict in favor of the defendant.

HOW TO RIDE A BICYCLE.

The proper position for a bicycle rider is, in the first place, an upright one. He should push nearly straight downwards with his legs—not backwards, as one must do who leans far forward. His arms should not be rigid and extended to their full lenth, but a little bent, and the handles can be easily adjusted to bring this about. The reason for the bent, or slightly bent, arm is evident after a moment's thought. If the arm is stiff, rigid, and extended to a full length, the "pull" which you give the handles on going up hill or, indeed, while running along a level road, is a dead pull. There is no life in it. Each jar to the machine is a jar to your body, your head and neck, and consequently a jar to your whole system. On the other hand, if you ride with the arms a little bent, and acting as a kind of buffer to all jarring influences, they will save you an injurious though unnoticeable shaking up each time you go out. The only way in which you will notice a change will be after you have become accustomed to the bent-arm method. Then you will find you can ride longer without becoming tired.

Another feature of this stiff arm is the position into which the shoulders are thrust. Try it; grow a little tired with a long ride, and then see where your shoulders are. You have gradually come to lean on your arms for rest. Both shoulders have been thrown far back; your head and neck are stretched far forward, and your chest has, so to speak, sagged forward out of its natural position. Keep this up long enough, and you will be a fine-looking specimen.

No, the weight of your body should never come on the hands and arms, but on your thighs, and thence be transferred to the seat, with the unconscious springy action of your legs, which in a measure allows some of your weight to come on the pedals. In this position your hands are free to guide your wheel; you body is erect; you do not then get into the habit of swaying from side to side to put more weight first on one side, and then on the other; and your whole muscular development is regular and normal. Try riding without putting either hand on the handles and sitting erect. If you ride well, you can easily keep you balance, and in an instant you will be in the correct position. Once in this position, place the hands lightly on the handle-bars, and you will be in a healthy, proper situation to gain benefit from your riding.

In riding ten miles, for example, I should never go the whole distance at one pace. Slow, steady riding has its merits, so has sprinting for short distances. When a good clear road looms up ahead, have a brush for two or three hundred yards with the boy who is with you. These little races are good things. They quicken your movements, and they keep you from forming bad habits, or letting your body sag into set, immovable positions. They also bring the muscles into a different kind of play.

In fact, in bicycle riding as in everything else, you should remember that there is a right and a wrong way; that you need not only endurance but speed, and that changing from one to another, keeping up variety, is one good way of avoiding bad habits.—*Harper's Young People.*

SOCIETY REPORTS.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

February 13, 1895.

ACETANILID VS. QUININE TO ABORT CHILLS AND FEVER; AND ACETANILID AS A DUSTING POWDER.

(See page 444.)

DISCUSSION.

DR. J. M. ANDERS: The paper which has just been read reports certain clinical facts of lively interest based upon personal observation. It seems strange at this time that anyone would assume to have obtained better results from the use of acetanilide in malarial intermittents than from the use of quinine. Unfortunately Dr. Brodnax does not offer any experimental facts upon which to base an opinion of the mode of action of the acetanilid. The well-known antiseptic action of the drug is the only explanation that I can offer. I believe that Dr Brodnax is a careful and reliable observer, and do not question the fact that cases of chills and fever were cured after even single doses of acetanilid. Although we have entered upon days of scientific therapeutics, I do not think that the days of rational empiricism have entirely passed away. We know that quinine cures chills and fever. Since that discovery nothing has been brought forward that will supplant quinine in the treatment of that disease. It is not impossible that such a remedy may be found; it may be that Dr. Brodnax has found it in acetanilid. I have met with cases of malarial intermittents in persons in whom there is an unpleasant idiosyncrasy against quinine. Now, in such cases, a better substitute for quinine than those we have at present would be welcome and of great advantage.

The question whether or not there are objections to the use of acetanilid might be asked. The statement has been made that acute dilatation of the heart sometimes occurs in intermittents. Now, it is known that acetanilid is a cardiac depressant, and in toxic doses has produced death by paralysis of the heart. While I do not consider this a bar to the use of acetanilid in the doses prescribed by Dr. Brodnax, I think that this influence makes it necessary to guard the heart during the time of its administration. If subsequent experience support these observations the profession and members of this Society should give a vote of thanks to Dr. Brodnax for a new remedy for malaria, and one which promises to rank as a specific.

DR. J. A. CANTRELL: My experience with acetanilid in the treatment of disease has been in two hundred cases, or more, of skin eruption, especially intertrigo and eczema. I believe it to be the antiseptic that we are looking for in the place of iodoform. It does not have any irritating qualities that iodoform has, and, in fact, a great many cases of iodoform irritation have been cured by it. In very moist cases of skin disease it acts as a drying powder and also as an astringent. In other cases, like zoster, it acts well, dries up the eruption, and apparently it acts as a stop to the disease; at least, it seemed at the time as if acetanilid had produced this action.

DR. G. G. DAVIS: Nobody would be more glad than myself for a satisfactory substitute for the foul-smelling iodoform. Combinations have been brought forward of boric acid and other substances with iodoform. The mixture of boric acid I prefer to the pure iodoform. The boric acid breaks up the lumps which the iodoform contains and makes it a more manageable substance as a dusting powder. I have also used acetanilid by itself, but have been unable to persuade myself that it is the equal of iodoform for surgical purposes.

DR. EDWARD MARTIN: I have used acetanilid in about a thousand cases of suppurating wounds, and my experience is, in these cases, that it is superior to iodoform. It is less toxic, for one thing. It is very common among surgeons to ob-

serve in slowly healing wounds dressed daily with iodoform certain nervous symptoms, headache, and so on, indicating iodoform poisoning. This is not seen in cases dressed with acetanilid; the wounds keep perfectly dry, there is no pus, and, of course, no odor, and the dressings keep as clean as with iodoform. I shall continue to use it in place of iodoform.

DR. DAVIS: I think that the direction of surgical progress as regards the application of powdered antiseptic substance in recent wounds is on the decline, and I have no doubt that both the iodoform and the acetanilid will be eventually much less used than at present. Dr. Halsted, of Baltimore, makes an application of silver leaf take its place. Of course, drying powders will always be used in the treatment of suppurating wounds.

Dr. Makuen presented

AN INTERESTING CASE OF RAPID SPEECH DEVELOPMENT IN ADULT, FOLLOWING OPERATION FOR TONGUE-TIE.

(See page 445).

DISCUSSION.

DR. THORINGTON: I would like the patient to say anthropological and ethnological. (The patient repeated them distinctly.)

DR. G. G. DAVIS: This is an extremely interesting case, and an instructive one. As regards the relative parts which the operative procedure and the painstaking instruction have played in bringing about the result, it would be extremely difficult to decide which of them contributed the most. The part that the tongue plays in speech is uncertain, and I doubt if it is ever very important. Of course, in a person who has talked, and then has been deprived of his tongue or part of his tongue, speech is still intelligible; but whether an individual that had the tongue removed in infancy, would learn to talk is indeed a question. In this case there might have been some anatomical condition that would cause limitation of movement of the organ, or acted as an obstruction to prevent his learning to speak, until later in life, he was able to undergo the systematic instruction which Dr. Makuen ordered for him, which might in itself be instrumental in producing speech. I regret that these means for overcoming defects of speech are not better known than they are among physicians. The simple division of a tendon may be followed by elongation; but in the case of the tongue the resulting scar-tissue might restrict its movement still further. In this case there is a practical demonstration that the tongue is more movable. The report of this case is an encouragement to others to repeat this method in similar cases. I do not think that it is extremely rare to find cases where no device is able to afford relief; this is so where there is difficulty in pronouncing those sounds which are produced by the tongue held in contact with the roof of the mouth, it being sometimes impossible to place the tongue there.

DR. MAKUEN: The remarks of the last speaker are very pertinent to the question. I am sure I cannot say which was the greater factor in the development of speech in this case—the instruction or the operation. Certain I am, however, that the one would have been of little value without the other, for during the three months immediately preceding the operation I gave him very careful drill, which resulted in improvement on certain words, but in no improvement whatever on all those sounds which require a free action of the tip of the tongue. It was only after the operation that he could give these sounds at all. The shortening which usually follows cicatrization was prevented by free exercise of the tongue and by frequent traction. He can protrude his tongue three-quarters of an inch further than before the operation, and as you see he has acquired great faculty in articulation.

Dr. Spivak reports a case of

VARICELLA COMPLICATED WITH GANGRENE OF THE SCROTUM.

(See page 447).

DISCUSSION.

DR. J. ABBOTT CANTRELL: I regret that Dr. Spivak did not give more of the history of his case. When Hutchinson (J.), ("On Gangrenous Eruptions in Connection with Chickenpox and Vaccination," *Proc. Royal Med. and Chir. Soc. Lond.*, 1882, vol. ix., No. 3, pp. 88-91) gave the name varicella gangrenosa to this affection he stated positively that it did

not occur with any other disease than varicella, but since that time he has somewhat changed that opinion. Besides being witnessed in connection with varicella it has been seen with miliaria rubra and lichen planus by Crocker (*Trans. Med. and Chir. Soc.*, December, 1888), with purpura by Moore (*Austrian Med. Journ.*, 1889), Büchler's case (*Amer. Journ. Med. Sci.*, Phila., 1889, vol. xcviii., pp. 265-268) occurring under bad hygienic influences. In addition to this it has been witnessed as an independent eruption, such as the cases recorded by Crocker (*loc. cit.*), Payne (*Trans. Path. Soc. Lond.*, 1884 85, vol. xxxvi., pp. 471-475), Abercrombie (*Trans. Path. Soc. Lond.*, 1879-80, vol. xxxi., p. 383), Bowley (*Lancet*, London, May 30, 1885, p. 98), Elliot (Morrow's *System of Genito-Urinary, Syphilogy and Dermatology*, vol. iii., 1894), and others will testify.

Witley Stokes (Crocker, *loc. cit.*) recorded it, in 1809, as a pemphigus gangrenosus; Bazin (Elliot, *loc. cit.*) also thought it to be a pemphigus; and Carpenter (*Illus. Med. News*, London, 1888-89, vol. i., p. 173) refers to a case under the title of pemphigoid varicella. Simon recorded an example under the name of multiple cachectic gangrene (Elliot, *loc. cit.*).

Its usual seat is at or near the buttocks, the inner and posterior portion of the thighs, although it may be witnessed on any portion of the body; thus, Büchler (*loc. cit.*) saw it affecting the mastoid process, the ear becoming involved in the destructive process later. Jameison (*Trans. Med.-Chir. Soc. Edin.*, 1886-87, 1888, vol. vi., pp. 19-21) witnessed a case affecting the head, face, back, and upon the right thigh.

It begins as an erythematous spot, scarlatiniform in character, and this was seen in Stanifooth's case (*Med. Press and Circular*, 1890, N. S., vol. xlix., p. 37) to precede any other change for twelve hours. This is followed by a papule, visicle, vesico-pustule or a pustule. These, one and all, rapidly change into a pustule, and after it reaches the size of a split pea, or even before it becomes that size, it ruptures, and we have the formation of a crust. The lesion at this time is surrounded by a reddish or pinkish-red, or even a livid zone. In a short time the crust begins to separate, and after its completion the process generally terminates, but this is not always so. When the crust has been removed we see an ichorous, ashen-gray mass or a purulent secretion at the bottom of the ulcer, which has a ragged floor, the ulcer looking to be a punched-out sore—in fact, resembling the condition we have when a vaccination pustule is at its height. When the disease begins, or is in connection with a vaccination, it is witnessed first on the same arm, but not at the point of vaccination. Constitutional taint seems to have an influence upon the aggravation of the disease, but this is denied by Hutchinson. Thus, in Payne's case the child died of acute miliary tuberculosis; Abercrombie's showed double pneumonia, with recent pleuritis of one side; Howard's (*Brit. Med. Journ.*, 1883, vol. i., p. 904) case showed dulness on percussion, the little patient dying of pyæmia, and the autopsy revealed abscesses in one lung, while two ounces of pus was taken out of the pleural cavity; Bowley's case died of convulsions the day after discharge.

The disease is supposed to be due to a parasite, although a constant germ has not as yet been demonstrated. Ehlers found the bacillus pyocyaneus in two cases, Kallinger found the staphylococcus cereus albus in one, and still others have been found.

The prognosis is favorable without the intervention of some complication such as lung troubles, as mentioned, syphilis having a deleterious effect.

Treatment must be upon the strictest hygienic basis, the patient is to be supported and given tonics, as well as the best of food; locally, antiseptics are to be freely employed.

DR. SPIVAK: I have simply reported my own case, and I did not intend to review the extensive literature of the cases which I have collected; neither did I wish to discuss the mooted questions in pathology. I reported my case on account of three interesting points: (1) There was only one lesion in my case, while all the cases reported hitherto were multiple; (2) the size was unusually large—about a silver dollar in circumference—as can be easily judged from the photograph; and (3) there is only one case reported where the genitala was mentioned to have been affected, and no distinct reference to scrotum made.

PERISCOPE.

IN CHARGE OF WM. E. PARKE, A.M., M.D.

MEDICINE

Typhoid Fever.

Acting on the experiments of Werner, at St. Petersburg, showing that one-half per cent. of chloroform will kill the bacillus of enteric fever, and of McIntire, that carbolic acid not only controls the development of the bacillus but acts as an antiseptic on the intestinal canal, Dr. R H. Quill, of the British Army Medical Staff, in India, where the fever is most fatal, has treated all his typhoid cases the past year with the combined remedy, without the loss of a single case. The treatment was commenced by three grains of calomel, to clear the bowels of their contents, and followed by a mixture composed of thirty-six minims of carbolic acid, two drachms of the spirits of chloroform, three drachms of the compound spirits of cardamon, two ounces of syrup of nemidesmus, and added chloroform water to make twelve ounces. Of this mixture two table-spoons were given the first day every two hours; the next day five doses of the mixture were given, in iced water, and ten doses each day after, until there was a fall of temperature and marked general improvement, when it could be gradually decreased to three doses during the twenty-four hours, which should be kept up, to prevent relapse, for a week after the temperature was normal. Digestion continued in good condition, tendency to diarrhœa was checked, there was an absence of tympanites, and there was at no time any tendency to delirium or stupor, and convalescence was rapid.—*N. Y. Medical Times.*

Dyspepsia Treatment.

Dr. J. B. Marvin has narrowed down the treatment of dyspepsia to very simple remedies. He finds that the mercurials yield the best results. Cases of biliousness are benefitted by either small doses of calomel, or calomel and ipecac, or the blue-pill. They relieve constipation and stimulate glandular secretion. Where these substances are contra indicated, he prefers salines in hot water, to wash out the stomach and empty the bowels.

Rest is next in importance. Though a certain amount of exercise be advisable, rest, together with long sleep, will be more necessary in nervous and hysterical persons.

Two patients with emesis were successfully treated by very small doses of potassium bichromate—one-tenth or one-twelfth grain (say one-half ctg.) in solution and on an empty stomach, two or three times daily.

In cases of deficient secretion, he administers hydrochloric acid in large doses (Ewald's method). Where there is hyperesthesia or some other neurotic symptom, he uniformly uses ammonium bromide (five to ten grains [thirty to sixty ctg.]) with half a fluid drachm (two c.c.) each of camphor-water and glycerin, adding sometimes one to two drops of Fowler's solution.—*Ex.*

Tic Douloureux.

Dr. Jarre presented a report on the causation and treatment of tic douloureux of the face. His conclusions are as follows (*La Tribune Medicale*):

1. The disease known as spasmodic neuralgia, epileptiform neuralgia, tic douloureux of the face, etc., is due to a peripheral lesion seated in the terminal extremities of the fifth pair.

2. The exact and invarible seat of this lesion is a more or less extensive portion of the alveolar border of the upper or lower jaw, which is the seat of a cicatrix consecutive to former accidents of different kinds.

3. The intracicatricial location of the original lesion brings tic douloureux into the same category as the neuralgia of the toothless, and the neuralgia affecting the stumps of amputated limbs, both of which are also of cicatricial origin.

4. The rational treatment of tic, therefore, ought to consist purely and simply of the ablation of that portion of the alveolar border comprising the original seat of the disease.

5. The ablation is done by first incasing the soft parts with the galvano-cautery knife, removing the alveolar border by the bone forceps or saw, and subsequently rasping the wound in the bone.

6. The operation is not at all grave; the wound dressed antiseptically heals, ordinarily, in a few weeks without complications.

7. The results so far obtained give reason to hope that we are now in possession of a simple, rapid and harmless means of curing tic douloureux, a disease which, up to the present, has been classed with incurable diseases.—*Dominion Medical Monthly.*

Subcutaneous Injection of Carbolic Acid in Rheumatic Affections.

Dr. Andre Martin (*Bulletin Generale de Therapeutique*) calls attention to the value of carbolic acid used by hypodermic injections as a means of relieving the pain of rheumatism and other painful affections. He was led to employ carbolic acid for this purpose by the observation of surgeons in the use of the method of Lister, that even very feeble solutions of carbolic acid possessed a considerable analgestic power when applied to wounds. Baccelli, in 1890, cured a case of traumatic tetanus by the hypodermic injection of carbolic acid, the curative properties of which were attributed by him to the

sedative effect of the drug upon the excitability of the cord. Backzy treated headache by carbolic acid fomentations. Kunze and Gillepsie treated articular rheumatism by hypodermic injections of carbolic acid. Gillepsie injected two fifths of a drop of a ten-per-cent solution into inflamed synovial sacs or just outside of the inflamed membrane. He attributed his success both to the anesthetic properties of the drug and to a specific effect upon the ptomaines secreted by the microbes of rheumatism.

Benedick, in 1892, cured many cases of functional spasm accompanied by localized pain by means of local injections of solutions of carbolic acid. M. Cheron, with others, have introduced phenic acid into the formulæ of their artificial serums. M. Martin, encouraged by the results obtained by others, has within the last two years employed injections of carbolic acid in one hundred cases met in military practice, comprising the following: Muscular rheumatism, articular rheumatism, peripheral neuralgias, wounds, pleurisy, intestinal colic, and other injections accompanied by pain. The results reported from this treatment are sufficiently satisfactory to warrant further trial, especially in cases of acute localized rheumatic affections.

The Antiseptic Properties of Formalin.

The employment of Formalin as an antiseptic for the disinfection of rooms and buildings has again and again been advocated on account of the volatile nature of the formic aldehyde vapors. Some idea of the penetrating qualities of these vapors will be afforded by the results of experiments laid before the Paris Academy of Sciences last week by M. Trillat.

These experiments had been conducted on a most extensive scale, the apparatus being tested in rooms varying in size from 20 to 300 cubic metres. the walls having been covered with germs of very resisting nature at different heights. Various infected articles were also placed in the apartments. The results led to the conclusion being formed that the vapors took effect equally well both as regards height and depth, that is to say, that in consequence of the great diffusive powers of the gas it travels equally in all directions. The force of penetration of these vapors appears to be so great that, although they were used very diluted with air, drapery infected with germs and entirely purified—the various septic organisms with which it was inoculated being destroyed. Even wood was penetrated to a considerable depth, and the chairman, M. Friedel, drew attention to the fact that such results could not be obtained by the vapors of any other substance.—*New Eng. Med. Monthly.*

A Fatal Case of Uncomplicated Chicken-Pox.

The *Australian Medical Journal* publishes an article by W. B. Nisbet, M.B., Ch.M., Ed., of Townsville, Queensland, in which he remarks that it appears to be a generally accepted fact that varicella is such a trivial disease that no treatment is required, and, as complications are extremely rare, no precautions are necessary to prevent their occurring. West writes, says the author, "The disease is one so void of danger that it hardly requires any treatment;" while Collie, in Quain's *Dictionary of Medicine*, says, "No physician has recorded a fatal case of chicken-pox." For this reason, says Mr. Nisbet, the following case is recorded, which might otherwise seem too trivial to be worthy of note: A healthy baby girl of eight months showed signs of the eruption of the chicken-pox on September 30, 1894. Four older children in the house also had it, and an epidemic of the disease was running through the town at the time, so the diagnosis was a matter of no difficulty. For the first three days the case progressed in the ordinary way, the rash being by no means copious and the constitutional disturbance unimportant. But on the fourth day a new crop of vesicles made their appearance, and were so numerous that by the sixth day every part of the child's body was covered, even the soles of the feet and the palms of the hands. The eruption showed no tendency to become confluent, except over the back, which was constantly rubbed by the restless movements of the child. On the seventh day numerous spots appeared on the tongue, on the hard and soft palate, and on the inside of the cheeks; these changed to irritable ulcers on the ninth day, causing great distress, and on the morning of the tenth day the child died, without any other complication making its appearance. The temperature remained at or about 102° F. during the illness, only once, on the evening of the fifth day, reaching 103°. It fell to 98.8° on the ninth day and remained normal up to the time of death.

Mr. Nisbet thinks that death was owing to the immense area of skin involved, in the same way as a very extensive burn causes death from shock in a child. The exhaustion evidently was so great that at the crisis of the disease, when the temperature fell to normal, no amount of artificial stimulation could avert the fatal issue.

Singultus.

In a paper published in the *Physician and Surgeon*, Dr. D. L. Parker reports four cases of persistent singultus and the treatment employed. In each of the cases all the usual and known remedies had been tried without avail. In each case also, although the hiccoughing had gone on to the point of exhaustion of the patient, relief was at once obtained by dry cupping the abdomen, in two cases by ordinary drinking glasses, in the others by a cupping outfit. The author thinks, though we cannot see it as he does, that "the *modus operandi* of this remedy seems to be that by drawing forward a portion of the abdominal wall and thereby tending to enlarge the abdominal cavity, enough force is exerted upon the upper side of the diaphram, by atmospheric pressure to overcome its spasmodic action."—*N. Y. Medical Journal.*

The Danger of Apoplexy During Narcosis in Elderly Persons.

Senger (*Deut. Med. Woch.*) calls attention to this danger during the narcosis of elderly people, especially in those cases where there is marked arterial sclerosis. He believes this accident has occurred in many cases where the diagnosis has not been made. He finds no such cases reported in anesthetic statistics or in the literature at his command. The case reported is as follows: A patient, fifty-six years of age, suffered from sarcoma of the breast, and healthy kidneys and heart, and her pulse was normal; the arteries, however, showed sclerosis. During the anesthesia there was no marked excitation, although there was some vomiting Suddenly, while the face had been red, it became deadly pale and cold, the eyes fixed and expressionless, the pupils dilated and reactionless; the pulse could not be felt. The respiration, at first marked, became shallow and gasping, and then ceased altogether for a moment. Although the symptoms pointed to a centric and non-respiratory source of troubles, the author immediately began restorative measures, artificial respiration, external heat, and all the most approved means. After a short time the pulse and respiration again became normal, more chloform was given, and the operation completed. When the patient recovered from the ether she complained of stiffness in the right leg and arm, and difficulty in speaking, which proved to be a partial hemiplegia of the right side, which had occurred during the narcosis. Clonic spasm followed after a time in the lower extremity, but not so markedly in the upper, while the patient complained of cold in the foot. After six days the motion returned in part to the arm, but there was a relapse; when the patient left the hospital there was still considerable lameness, the leg having been slower in recovering. Two years later the paralysis had mostly disappeared, the foot dragging only slightly. The author believes this danger is greater with ether than with chloroform, as the arterial pressure is sustained longer in the former, and that consequently in elderly people with sclerotic arteries chloroform should be the anesthetic of preference.—*Amer. Jour. Med. Sciences.*

An Antidote to Hydrocyanic Acid.

The *Lyon Medicale*, says that M. Johann Antal, a Hungarian chemist, has discovered a new mineral compound, nitrate of cobalt, which promises to be a very efficacious antidote in cases of poisoning with potassium cyanite or hydrocyadic acid. Tried first on animals, this product has since been employed, always successfully, in more than forty cases of accidental poisoning.—*New York Medical Journal.*

Typhoid Fever in Infants.

The profession is gradually beginning to appreciate the fact that typhoid fever is more common in infants than was formerly believed. Various writers have contributed evidence to support this statement and Dr. I. N. Love concludes an article on this subject in the *Journal of the American Medical Association* as follows:

1. Typhoid fever occurs frequently in children than is generally supposed.
2. The fact that ulceration and hemorrhage is much less frequent would explain the absence of pronounced abdominal symptoms.
3. The erratic, undeveloped and hypersensitive nerve centers in early child life explain why the toxic secretions of the Eberth bacillus should make cerebral symptoms very pronounced.
4. Given a child of any age with or without intestinal disturbance, with a continued elevated temperature, with or without marked evidence of cerebral disturbance, the possibility of the presence of the Eberth bacillus of typhoid fever should be constantly kept in mind.

A Case of Peripheral Paralysis Following Varicella.

The case is reported by William Guy (*British Medical Journal*). The attack of varicella was mild, but about a fortnight after he was found in the morning to be completely paralyzed in his lower extremities. No paralysis in other parts. For three weeks there was no improvement. Shortly after this he made attempts at walking, but recovery was slow. At the end of three months he could walk fairly well. In addition to the complete muscular paralysis, there was considarable sensory loss. All the muscles of the lower limbs were involved, but the extensors were more profoundly affected. Knee-jerks and plantar reflexes were absent. Abdomidal reflexes were active. The child, which was two and a half years old, was slightly rachitic, but there was no sign of syphilis.

Infantile Scurvy.

In connection with a paper on infantile scurvy, Dr. Fruitnight reports the following case (*Archives of Pediatrics*) A boy, nine years of age, had, for a long time, subsisted on a diet made up chiefly of salted meats, dry rye bread, and black coffee. When seen by the author he had complained greatly of pains near the knee joints, which his mother termed "growing pains." There were oval swellings about both knee joints; they were very sensitive to pressure, and the boy made no attempt to walk, retaining the same position constantly on his chair, except when he would lie down. His gums were spongy, sore, and swollen, and bled very easily. He showed many minute ecchymotic points. His teeth were loosened and covered with tartar. Breath very foul. He had alternate constipation and diarrhœa, and was very anæmic. He was put upon anti-scarbutic diet, potatoes, fresh vegetables, fruits, lemonade, beef and mutton, with citrate of iron and quinine, with dilute muriatic acid three times a day. Within ten or twelve days he was practically well.

Smallpox Ameba.

Dr. Maximilian Herzog, of Chicago, claims to have discovered a "smallpox ameba," the presence which in the blood on the first or second day after vaccination is the only sure test of a successful vaccination. No matter how swollen the arm or uncomfortable the patient, the vaccination is not effective unless the "ameba" is found, the unpleasant symptoms being due to the vaccine points being loaded with croton oil, or some other irritant—*Boston Medical and Surgical Journal.*

Digestibility of Sterilized Milk.

Bendix (*Jahrbuch fur Kinderheilkunde*), has made researches upon sound and sick children as to the digestibility of both sterilized and nonsterilized milk. He concludes:

1. That in healthy children there is no difference as to the digestibility of the two milks.

2. In sick children the sterilized is digested just as well as the unsterilized, notwithstanding the fact that the absorption of fat and nitrogen is so much reduced in such children.

3. The taste and smell of milk, while they may be changed by sterilization, are not materially so, and sterilized milk is readily taken by children.

4. He has never seen the health of children badly affected by the use of sterilized milk. On the other hand, they eat well, grow, and their stools are normal, and they never have vomiting.

5. The transmission of severe diseases from animals to men is prevented by the sterilization of milk.

6. Sterilization is much preferable to Pasteurization, and heating the milk to 212° F., while it does not hinder its digestion, absolutely kills all bacteria and spores.

On the Value of Quinine as a Remedy in Cholera.

In this paper, which appears under the title of Is there a Better Remedy in Cholera? the writer strongly advocates the use of quinine, given either in powder or in solution by the mouth, as a remedy in this disease. Reviewing the list of remedies which kill the germs, he says that it is manifestly impracticable to kill the sprilla outright in the intestinal tract of a human being whom we expect to live, hence he looks for the least harmful inhibitant, which he considers undoubtedly to be quinine. Twenty or forty grains of quinine, given by the mouth, is sufficient to inhibit the development of the microbe in any quantity of the rice-water exudate presumably present in the alimentary canal. Absorption takes place to a very small degree on account of rapid peristalsis. Therefore symptoms of cinchonism are not noticed, even after repeated doses. He quotes statistics to show that in those cases where it was given in full doses by the mouth it has lowered the mortality in severe cases to twenty-five per cent., and only in those cases where it is has been given hypodermically did it prove ineffectual. At the same time other means of treatment should be made use of, as may be found necessary; the application of heat to the body, saline subcutaneous injections, and morphine, and small doses of calomel for the diarrhœa.—E. B. Fullerton, M. D., in *New York Medical Journal.*

Ipecacuanha in Alcoholism.

Dr. W. F. Waugh, writing to the *Medical World* says: In treating a man for alcholism I wanted to put something in his whiskey to sicken him, and so gave a little fluid extract of ipecacuanha—about 20 minims. It did not nauseate him, but he went to sleep and slept all night. This seemed curious, as he had previously taken 40 grain doses of chloral and of sulfonal, without inducing sleep. Next day I gave him the same dose, without the whiskey and he slept all day. Following this, for a week, I put him to sleep every night on the ipecacuanha, and he had the best week's sleep he had had for years. I gave him the fluid extract, 10 to 30 minims, in a spoon with no water, and directed him to lie perfectly quiet for five minutes after taking the medicine, in order to avoid nausea and vomiting. This is the way to give ipecacuanha for the grave forms of dysentery. Now if this drug will give sleep in such cases it is of importance, for we know that very often they resist such drugs as opium, chloral and bromides, until such hugh doses have been taken that life is endangered thereby.

Indications for Iron.

Iron is indicated in all anæmias unless they are accompanied by fever or due to some malignant disease. In chlorosis the carbonate, made extemporaneously by combining the sulphate of iron with the carbonate of potassium, should be used.

After fevers there is always more or less anæmia.

The weakness of the muscular system is shown by the acceleration of the pulse, due to cardiac weakness on the slightest exertion, as setting the patient up in bed. Iron combined with restoratives should always be given.

In Bright's disease, the muriate tincture, combined with corrosive sublimate and sweet spirits of nitre, can be given.

In diabetes, iron should be given; constipation should be carefully guarded against. The iron should be given with a laxative.

Nervous exhaustion, accompanied by the accumulation of phosphates and hæmatin in the urine, calls for iron.

In chronic constipation of women; uterine disease, characterized by weakness of the uterus or its supports prolapsus uteri, etc.

Early Signs of Pregnancy.

It has been taught that the diagnosis of pregnancy in the first three months is very

difficult or even impossible. This Dr. Charles P. Noble contradicts in the *Philadelphia Polyclinic* In his experience, careful abdominal palpation will make it out as early as the sixth week or at any time between the sixth and twelfth weeks. The sign, he says, has never failed him in his dispensary work, but almost all of these cases came in to see if pregnancy existed, and as they were illegitimately pregnant it was possibly rather an easy guess. The shape of a virgin uterus is pyriform, while a uterus in which there is an ovum but a few weeks old will have grown sufficiently to cause the body and fundus of the uterus to assume a spherodal shape.

The conditions which he found to simulate pregnancy were hematometra, which is very rare and usually occurs at the time of puberty; and intramural fibroid tumors, which on account of the asymmetrical shape given to the uterus, may be left out of the question. When pregnancy occurs in a uterus where there is already a fibroid or if the uterus be jammed between tumors of the ovary then the diagnosis is very difficult, and when the patient is very stout palpation is not easy. Still, in general, he thinks a pregnancy can be told with certainty in the first twelve weeks and he emphatically makes this statement in view of his large experience.

The Treatment of Warts.

The *Union Medicale* says that when one has to deal with isolated warts, they must be taken off with a scoop; a rather abundant hemorrhage follows, which may be arrested by compression or by cauterization. When warts exists in large numbers, this procedure is no longer applicable, particularly on account of the numerous cicatrices that follow its employment. In these cases the better way is to shrivel the excrescences with nitric acid. The tincture of thuja is also a very efficacious topical application.

In cases of condyloma the small tumors may be dusted with powdered resorcin or salicylic acid; they may also be covered with a plaster containing these substances in the proportion of from ten to twenty per cent. When the face is studded with a large number of these little warts, which often appear suddenly, Dr. Kaposi covers them with a piece of flannel spread with a layer of black soap. This is left on the warts for twenty-four hours and adheres to the skin, gradually becoming detached with the warts.

Another very good application is the following mixture: Flower of sulphur, 20 parts; glycerin, 50 parts; pure concentrated acetic acid, 10 parts. The warts are painted with this mixture for several days without taking off the first layer, and gradually the excrescences dry up and become detatched.

For keratosis of the palms of the hands and the soles of the feet plasters of resorcin and salicylic acid are also efficacious. If the case is one of molluscum like nævus it is better to employ electrolysis. The needle connected with the positive pole is plunged into the tumor, and a current is passed of from one to two milliamperes for about thirty seconds. This operation is repeated at the end of eight and fifteen days. When the nævus is very large, the galvano-cautery is preferable.—*New York Medical Journal.*

Ætiology and Treatment of Cystitis.

The author, M. English, (*Le Semaine Medicale*), had already observed that cystitis is not always of microbic origin, but may be due to chemical irritants or to traumatism. He has recently observed four cases of a new variety described as epidemic cystitis. Two important symptoms among those that characterized the disease were retention of urine and profuse hemorrhage following the use of the catheter.

The influenza has a decided effect upon the urinary organs. Existing disorders are augmented, and in previously healthy subjects urinary symptoms are manifested during the influenza, notably hæmaturia.

Among the causes of cystitis are mentioned disease of the kidneys, ureters, prostate and urethra, chemical modifications of the urine (oxaluria, etc.), and, lastly, affections of the central nervous system, such as tabes, and arteriosclerosis and certain chemical agents.

As to treatment, when of constitutional origin, the diathesis is first to be combated. The local treatment depends upon the condition of the mucus membrane of the bladder. Catarrhal cystitis is best without local treatment. Purulent cystitis always demands local treatment. Lavage of the bladder is very important in carcinomatous and tubercular cystitis. Solutions of boric acid are ordinarily to be used; the use of nitrate of silver frequently causes severe inflammation.

Scarlatina and Measles Coexisting in the same Person.

On June 29th last I saw a boy of nine who had sickened and complained of sore throat that morning; next day a scarlatinal rash was undoubted. By July 6th desquamation was distinct on neck, breast, abdomen and thighs. On the 9th he had severe coryza and a constant irritating cough On the 10th I found him covered over with a most intense eruption to measles. Desquamation, as if accelerated by the second skin attack, proceeded with unusal rapadity. I was not able to trace the source of infection, but it is noteworthy that the two poisons must have found a lodgment in the child at much the same time. The boy made an excellent recovery.—*James Ferguson, M.B., C.M., in British Medical Journal.*

Nutmeg Poisoning.

Nutmeg is seldom used in medicine except as a flavor, but as a household spice it has long been helpful in flatuency. Cases of poisoning from its use are not common and for this reason the one reported by Dr. Alexander L. Hodgdon, in the *American Medico-Surgical Bulletin*, is of interest. The patient ate four nutmegs within a few hours and went into a state of alarming collapse. By the use of heat and such cardiac stimulants as caffein, digitalis, nitroglycerine, etc., all evil effects were removed and the case recovered.

Strontium Bromide in Gastritis.

An Italian physician says that strontium bromide is particularly valuable in gastric affections, especially acute catarrh, which, he says, shows anew the remarkable favorable action of the drug. Carseli uses a syrup by dissolving

Strontium bromide.....	gr. xxx.
Syr. bitter orange peel.....	fl. ʒj.
Distilled lettuce water	fl. ʒiijss.

This amount is to be taken daily in three doses, during and after meals. It stops the vomiting and lessens pain. It is thought to act both directly upon the nervous system and as an antiseptic, arresting fermentation and thereby reduciug the flatulent distention that gives rise to the pain.

SURGERY.

Caution to Anesthetizers.

During a recent clinic by Prof. Hunter McGuire in the new amphitheatre of the College of Physicians and Surgeons, Richmond, Va., while chloroform was being administered to a patient on whom excision of portions of the bones of the leg was about to be performed; the patient suddenly stopped breathing, the face became purple, while the heart continued to beat. In a moment Dr. McGuire recognized that the condition was due to the dropping back of the tongue, obstructing breathing. With thumbs behind the rami of the inferior maxilla, he pushed the bone forward, thus lifting up the tongue, and the patient at once began breathing easily, and was kept thoroughly under the anesthetic for the time necessary for the operation. While this procedure is not, by any means, a new one, it is worth while to record such incidents so as to keep the surgeon or physician well on his guard so as to act the moment when bystanders are dazed at the shock of an impending accidental death. In short, in using an anesthetic keep your wits about you and look out for the sudden emergencies. —*Virginia Medical Monthly.*

The Danger of Anesthetizing Diabetics.

The danger of narcotizing diabetics is not as generally known as it should be. As many as twelve fatal cases have been recently recorded. Even in slight cases of diabetes, patients are apt to become comatose and die. Not immediately, but several hours after the chloroform narcosis has passed off. They become indifferent, stupid and confused. Finally lose consciousness, pass into coma and die.—*Charlotte Med. Jour.*

Two Cases of Intraperitoneal Rupture of the Bladder.

Coats records (*British Medical Journal*) two fatal cases of rupture of the urinary bladder, and adds the post-mortem records. In studying these cases the following points seemed especially worthy of comment:

The absence of a clinical diagnosis in both. There was no clear history of violence in either case, and the symptoms were obscured by the fact that one patient was maniacal and the other deeply intoxicated.

The seat and size of the rupture were similar in the two cases. The tear was found in the posterior wall of the bladder, a short distance from the fundus, being circular in the first case and transverse in the second.

The interval of time between the rupture and the death of the patient was in the first instance five days, and two to three days in the last. Of 85 cases collected by Rivington, 8 died within twenty-four hours; 15, within two days; 15, within three days; 16, within four days; 10, within five days; 4, within six days; 5, within seven days; 5, within eight days; 1, within nine days, whilst 1 lived twelve days; 1, more than twelve days; 1, fourteen days; 2, about fifteen days; and 1, sixteen clear days.

The absence of peritonitis was a surprise to the author, who states that none of the ordinary evidences of acute peritonitis were present.

Absence of inflammatory reaction in the wound was noted, particularly in the first case, even in the microscopic examination of the edge of the wound and adjacent bladder wall. Ferraton, in 1883, recorded two cases that received external wounds simultaneously with rupture of the bladder; he observed that at the time of death the wounds presented exactly the same aspect as at the time of admission to the hospital—"they presented no trace of a process of inflammation and repair."

The mode of death is directly related, in the opinion of the author, to the absorption of the urine by the peritoneum, and its continuous accumulation in the blood, to which condition Coats applies the term "urinary poisoning."

NEWS AND MISCELLANY.

The Rules and Regulations that will Govern the Division of Pathology Bacteriology and Disinfection of the Board of Health of Philadelphia.

The Sanitary Committee of the Board of Health submitted to the latter body at its meeting to-day a series of rules and regulations that will govern the recently organized division of Pathology, Bacteriology and Disinfection, of which Dr. B. Meade Bolton was recently appointed the Chief Bacteriologist. The rules and regulations which were adopted are as follows:

There shall be organized a Division of Pathology, Bacteriology and Disinfection, to be called the "Division of Pathology, Bacteriology and Disinfection of the Board of Health." There shall also be organized and established, in connection with the above-named Division, a laboratory for bacterio-

logical investigation and experimental research on questions pertaining to public health and hygiene. The Division of Pathology, Bacteriology, etc., shall be in charge of a chief, who shall be a physician, and an expert in bacteriology and well versed in pathology and the methods of investigation. He shall be called the "Chief of the Division of Pathology, Bacteriology and Disinfection" and "Director of the Laboratory of Hygiene" of the Board of Health.

He shall have an office in City Hall in connection with the office of the Board of Health. The laboratory shall be located in City Hall, where the best facilities for conducting the entire experimental work of the Division shall be provided.

The chief shall be held responsible to the Board of Health for the reliability of the work of his assistants and the proper use and custody of the property connected with the Division, and for the active, progressive and efficient work of the office.

He shall, so soon as appointed, prepare a plan for the establishment of the laboratory, and furnish an outline of the work to be undertaken, and draft rules and regulations for the government of this work, to be submitted for the approval of the Board of Health.

The scope of the work imposed under this new division shall be extended, so far as practicable, to all questions which affect the public health, relating both to preventive and curative medicine; the latter, so far as it includes the preparation of means for the prevention and curtailment of diseases by such processes as vaccination, the preparation and directions for the use of such material as the anti-toxin of diphtheria and sterilized serum of rabies, etc., etc.

There shall be two assistant bacteriologists, one clerk (who shall be a stenographer), one helper, one messenger, and three collectors of culture tubes.

So soon as practicable after the establishment of the laboratory, steps shall be taken to prepare, in ample quantity for the use of the city, the anti-toxin of diphtheria after Behring's or Roux's method.

Steps shall also be taken at once for the prompt examination of all specimens of exudate from throats of "suspected" cases of diphtheria and report thereon, the proper announcement being made to physicians of the facilities afforded by making prompt and reliable tests and the means of taking advantage of them.

The Chief of the Division of Pathology, Bacteriology, etc., shall report regularly to the Board of Health upon the work of his division, and as the work more particularly concerns measures for the management and suppressions of contagious and infectious diseases, he shall be in close communication with the Sanitary Committee of the Board of Health, and subject to their direction and control.

The laboratory shall be provided with a telephone to facilitate communication.

The Chief shall keep himself in constant communication with the medical inspector so as to place at his disposal all information that will be of practical aid in the successful management of the Division of Contagious and Infectious Diseases, especially such information as has a bearing upon the duration of the period of isolation and of quarantine, and the time for disinfection as determined by bacteriological examination.

The chief shall prepare, for the purpose of making bacteriological diagnosis in suspected cases of diphtheria, the necessary culture outfits and printed for distribution to stations at convenient points throughout the city. A list of these stations shall be published, at which physicians can obtain the outfits free of cost. The culture-tubes shall be collected once a day, or oftener if deemed advisable by the chief. When cultures are not made by the attending physician, they should be made by the assistant medical inspector, when no objection is raised by the attending physician. A report in all cases should be made as soon as practicable to the attending physician of the results of the bacteriological test, either by mail or telephone.

Diagnostic tests shall also be made for physicians who desire it in all cases of suspected tuberculosis whenever specimens of the expectoration are left at the station or sent direct to the laboratory.

The chief shall prepare printed forms to be filled out by physicians, and to be filled out in reporting to physicians the results of the cultures, and such other forms as may be used in the office.

The chief shall make requisition upon printed form to the Sanitary Committee for all the supplies needed. He shall mark as correct all bills that meet his approval.

The chief of the Division of Pathology, Bacteriology, etc., shall advise from time to time the best means of increasing the efficiency of the work of the disinfecting corps, and shall arrange for a practical course of instruction on "Disinfectants and Their Uses," to be given to the members of the corps.

The work of the Laboratory of Hygiene and of the Chemical Laboratory shall be cooperative in furthering the chief purpose of their organization.

The Laboratory shall be kept open from 9 A.M. to 6 P.M.; and, as the interruption of the work of making diagnostic tests may jeopardize life, provision shall be made for the continuous and uninterrupted prosecution of this special branch of investigation.

The Assistant Bacteriologist shall be under the special supervision of the Chief, and shall be responsible to him for the faithful and efficient performance of the duties assigned to them.

The object of the establishment of the Laboratomy of Hygiene is not merely the application of knowledge for the benefit of the community. The purpose of its establishment is also the utilization of accumulated data by drawing deductions therefrom, experimental research in the field of the etiology of disease, and the study and investigation of all subjects related to preventive and curative medicine so far as they appropriately come within the scope of such an institution.

THE
MEDICAL AND SURGICAL
REPORTER.

ORIGINAL ARTICLES.

THE EDUCATION OF MEDICAL MEN. HOW AND WHEN?

A. L. BENEDICT, A.M., M.D., BUFFALO.

Let me admit at the outset that this question, though for some time in mind, would probably not have taken the form of a journal article, had it not been for the series of editorials entitled "An Overcrowded Profession," which have recently appeared in THE REPORTER.

There is an old puzzle that relates that the captain of a ship, being short of provisions, found it necessary to diminish his crew which was composed of white men and negroes. He, therefore, proposed to range the men in line and throw overboard every tenth man, counting back and forth along the line. The proposition seemed a fair one but the captain managed to arrange the sailors so that only the negroes went overboard. A very similar problem lies before our profession, and the solution is, theoretically, easy enough.

But, leaving aside the economic aspect of the question, let us consider how those intending to enter our profession can be best educated. If I speak of my own observations in this matter, it is not on account of egoism, but because one can deal better with personal experience than with general statistics. In the last ten years, the usual course of medical study has been advanced from a two-year to a three-year standard, and there is every prospect that, within the next year, another year will be added. This is a tremendous improvement, but it must be remembered that probably a majority of the men who inaugurated this reform and who are given the best medical instruction, are practicing under diplomas conferred after two short sessions. Moreover, however long a student may stay in a medical college, and however fortunate he may be in his hospital service, he still will go out into practice inexperienced, while his rank in the profession after five, ten or twenty years will depend, not on what he has learned at college, but on his subsequent work. The best course of study preliminary to graduation, therefore, is not necessarily that which sends out the best informed doctors, but that which has best equipped its students to continue their studies. The best physician is the one who has the greatest ability to comprehend general principles and to adapt them to individual cases. Such a man must have a broad training. He must understand many chemical and physical principles which are not included in the medical course. He must be able to meet his patients and representative men of other professions on a par. He must be able to express himself correctly and to

know the ultimate meaning of the words he uses. In short, he must have a good general education. If the lengthening of medical courses shall tend to dissuade students from taking proper preparatory training, it would be better to take a step backward, for a well educated man with two years' drill in purely medical subjects is better able to cope with the problems that will confront him in after life than the boy who supplements the spelling book and reader with four, five, or even six years in the narrow rut of professional study.

As a student the writer attended a college in which three years of study were required, of which the first might be with a preceptor. Comparing for several years the men who chose respectively two and three-year college courses, there is certainly no marked superiority on the part of the latter, in fact, judging both from work before graduation, and from apparent success afterward, the writer is inclined to think that the balance is in favor of the two-year men, although their study with a perceptor was largely a matter of imagination. The reason was this, that the two-year men were as a rule ambitious and, having a better preliminary education, were allowed to stretch the strict construction of the law in regard to their study under a perceptor while a man not so well prepared would be advised to take the slower course.

The writer had an experience with the beginning of the four-year course that was not very favorable. Some time after graduation he went to a large college for a post-graduate year, expecting to enter the fourth year class. But as then organized, this consisted mainly of a miscellaneous collection of specialties. Nervous diseases, dermatology, eye and ear, throat and nose, gynecology, with the clinics and some of the lectures of the ordinary senior course, made up this remarkable assortment. Now, granted that a man wished to take the fourth year course with some one specialty in mind—which was not true of a single member of the class of that year—he would scarcely want to devote himself to so many others and, in the case of only one specialty, was the work so planned that it would include more than the merest rudiments. However, it would be manifestly unfair to judge the present standard of fourth-year work by this experimental beginning. But this point must be thoroughly understood, that no amount of purely technical training will atone for the lack of preliminary education, and that a four-year or five-year course in medicine, plus a previously uneducated student, will simply produce an artisan, not a professional man.

The man who has studied medicine, as he would learn a trade, is not fitted to take a broad view of life nor to combine properly the horse sense, tact, sound logic and actual remembrance of facts as the truly successful physician must. Certain exceptions exist that prove the rule. There is the ignorant man that makes a financial success of medicine and the cultivated one that, somehow, lacks the element of practicability. There is the man who absorbs education and refinement from the atmosphere, apparently, and the one whom no amount of literary and scientific training can change from the raw, uncouth, ignorant fellow that he was at the beginning. I am speaking, however, of the plain, every-day man who becomes what his environment makes him.

The determination of the exact amount of preliminary education to be required of the medical student, is a matter of considerable delicacy. Probably if a circular-letter could be sent to the members of the profession asking their reply to such a question, the answer would in general correspond quite closely to actual attainments of those addressed. After a great deal of political opposition, the profession of New York has succeeded in having a bill passed requiring an ordinary grammar school education as a minimum for the prospective medical student. On the other hand, one or two medical schools are seriously considering the question of requiring a bachelor's degree for admission. We must acknowledge that even the New York law has produced a decided improvement in the average ability of medical classes, though it is a disgrace to our profession that such an admission is necessary. For the present, of course, the requirement of a bachelor's degree or, for that matter the requirement of six fingers and toes, would work no harm to the profession and the laity as a whole. However, the rights of medical schools and of those who desire to adopt the profession of medicine, must be considered, and it seems to the writer that under existing

circumstances, the requirement of a collegiate education is rather unreasonable, although there can be no objection to its adoption by a few schools. A fair compromise between the two extremes would consist in the establishment of a high school education as the standard. Such an education can be obtained in every city and in nearly every village of the country at no expense beyond that of living and the cost of a few books.

Admission to medical schools should depend upon the permission of an absolutely impartial board of examiners, not connected in any way with medical institutions. Such boards could be easily organized from academic teachers and superintendents of education and they would have the practical knowledge that would render possible the formulation of rules to determine the acceptibility of the diploma of any given high school or academy and to examine candidates who had no diploma but who claimed an equivalent training.

With the general adoption of some such provision, either by legislation or by the concurrent action of respectable medical schools, there would arise a demand for preparatory medical instruction which has been anticipated by one or two colleges and which would justify the establishment of special courses in most of the prominent academies and colleges. Such courses would lighten the labors of medical teachers and would allow them to presuppose some degree of familiarity with physiology, chemistry, etc., and thus elevate the character of instruction in these branches in the professional school.

By checking the current of candidates at the entrance to the medical school instead of at the end of the course, much dissatisfaction could be done away with and the diminution of the number of students would be more effectually accomplished. Students have a very natural feeling that, having been allowed to matriculate and having paid for their medical instruction, they have in a measure paid for their diploma in advance. At the final examinations it is almost inevitable that one or two students pass whose success is a surprise to themselves while one or two others who are really better men, fail. Some students seem to regard the matter as a lottery. They argue that the expense is not high, and only two or three winters are taken up while their business or leisure need not suffer during the rest of the year. Without any special effort, they attend most of the lectures and clinics, gain a smattering of the subjects taught and take the examination with the consciousness that they have everything to win and comparatively little to lose. Other students take up medicine, not from any love or fitness for the subject, but because they would rather "doctor" than pitch hay, cut hair or drive a street car, and because, under existing circumstances, less is required of the physician in the way of preliminary training than of any other professional man. Now, there is no disgrace in any honest work, but manual labor, by common consent, is considered less desirable and is compensated at a less rate than are the professions. Hence, it is no affectation to consider medicine an occupation of higher grade than those mentioned and any young man ought to be encouraged to better himself, providing he does so honestly, in other words, if he will fit himself intellectually for what he wishes to undertake.

But, at the end of proper preparatory study, the hay pitcher, the barber and the driver are no longer choosing between staying where they are and taking up a medical career. If they are so inclined, a more comfortable and nearly or quite as profitable a profession lies before them as teachers or ministers. Opportunities in business, law, journalism, politics and a host of other fields open before them which were previously not even dreamed of. What will be the outcome? Medicine will be chosen only by those who have some particular liking for it and we shall have eliminated that class of medical students who feel that if they can only graduate, they cannot have so poor success as to make them worse off than they are at present. Thus, it seems to the writer that the insistence on proper preliminary education will not only accomplish a greater reform than any degree of increased medical study but that the economic question raised in the series of editorials already referred to, will be satisfactorily settled. The writer does not wish to be understood as condemning the effort to increase the instruction in medical colleges. But let the reform begin at the foundation, before any radical change is made in the superstructure.

APPENDICITIS.

M. PRICE, M.D., PHILADELPHIA, PA.

The trouble is often, if not very generally, looked upon by physicians and surgeons from radically different standpoints and not with that cautious and experienced judgment which the exigencies of the case and the welfare of the patient in many instances demands. The surgeon operates upon many cases not requiring such radical treatment, removing healthy appendices when the real trouble was impacted bowel—removable by some simple laxative. The physician on the other hand often claims cures for a condition that never existed; he treats impacted bowel or other local trouble medically and through mistakes of symptoms, or through some not over worthy professional motive, claims a cure for appendicitis.

It must be granted that the condition is not infrequently attended with obscurities that perplex the most experienced physician, and put to severe test the best surgical judgment.

It has been within the experience of all physicians of extensive general practice to find in a number of cases a condition existing in the right iliac-fossa, a condition so closely simulating appendicitic abscess as to require the skill and experience of one thoroughly familiar with such conditions, and of sound, enlightened surgical judgment to differentiate an appendicitic condition from one closely simulating it. There are a few symptoms in this condition that go to clear up the diagnosis. Where appendicitis exists there is always great tenderness in the right iliac-fossa—with but slight or no induration, with a temperature sub-normal the patient continues to grow worse, and as the case goes on you find induration increasing and a mass in the right iliac-fossa augmenting in size, the sub-normal temperature continuing you have little or no reason to doubt that you have an appendicitic abscess or an abscess at the head of the colon requiring surgical treatment, whether one or the other. We will not maintain that all cases of appendicitis present such low temperature, but that it is an exception for them to suffer from high temperature—the rule is a low or sub-normal temperature. And in all genuine cases a well marked abscess exists.

In the great number of cases we are called upon to treat surgically—the operative cases—we find, with but rare exceptions, a sub-normal temperature, running as low as ninety-six in some cases, and an abscess is found in every case, and the necessity for the removal of the appendix in about one-tenth of the cases.

Drainage being about all that is necessary in the greater number of cases. The condition is usually found to have existed from about two to six days. Those not operated upon may be, and very frequently are, those with a temperature ranging from one hundred and one to one hundred and three with constipation and with no indication of sepsis. These cases in the experience of most successful practitioners and surgeons, in proportion to those operated on, are about as ten to one. Clearly the cause of the trouble in largely the greater number of cases is a foreign body at the head of the colon—either undigested food, nuts, seeds or some undigested substance taken in as, or with food.

In these cases the symptoms do not abate until the foreign body has been dislodged from its position and purged away. It is frequent that the treatment of these cases extends through such a length of time as to preclude all idea of abscess of the appendix, for such a condition would early have proven fatal unless relieved by surgical treatment.

Nature in some of these cases anticipates the surgeon and kindly comes to the relief of the patient. We meet with cases of genuine appendicitic abscess where the contents have been emptied through the vagina, in exceptional cases through the bladder, and in many instances through the head of the colon. In a number of cases operated upon there is found in the head of the colon a number of openings so much diseased that fæces pour out through the external wound for a number of days after the operation. About all these cases,

where the surgery is timely, carefully and skillfully done, recover. The deaths from appendicitis usually occur in those cases where a diagnosis has not been made, where a genuine peritonitis existed when the patient was first seen, where opium had been used in large doses and the patient septic beyond help.

No one doubts that in the hands of experienced and competent men the diagnosis can and should be correctly made.

But the credulity of the profession is severely taxed by the many reports in medical journals of long lists of consecutive cures of appendicitis in cases where the temperature was 101° and 102°. Are we not justified by the experiences of many eminent physicians in concluding that a mass of fæces in the right iliac-fossa has been mistaken for pus. And we cannot fail to be further convinced when we see a hundred or more operative cases reported, and that of these from fifty to seventy-five per cent. were without adhesions, that the surgeon has been wantonly invading the domain of the general practitioner. Sometimes we hear this operation justified in cases where by no process of pathological reasoning can it be justified, repeatedly, there is set up the flimsy, absurd claim that if he has not got it now he will have it and further that the condition is such as furnishes a playground for dangerous microbes.

To these microbe apostles can be applied that fine touch of ridicule with which Dr. Conan Doyle in his "Round the Red Lamp," credits the good old Dr. Winter. "Shut the door or the germs will be getting in," and from the statistics of the cures claimed we would infer that the claimants possess all the skill and magic of the good Dr. Winter. "He would shoo death out of the room as though he were an intrusive hen."

In 1893 I saw a boy with Dr. Weaver, 63rd and Woodland avenue, who was supposed to be suffering from appendicitis. His little sister had died one year previous, a post-mortem revealing in her case an appendicitic abscess. We saw the boy on Monday, found him with the following symptoms: temperature, 103°; pulse, 130; skin, dry and harsh; a well marked tumor in the right iliac-fossa, which was present on Sunday afternoon when Dr. Weaver made his first visit. The boy was suffering great pain, with both extremities drawn up. He complained of great pain during the examination. He was 13 years old and much overgrown for his age. On the previous Saturday he had been slightly injured in the right groin by a fall on the railroad. He complained of this pain until Sunday morning, when he was offered a ride on horseback which he took without complaint for a number of miles. In the afternoon of that day (Sunday) he complained of great pain in the right iliac-fossa, and Dr. Weaver was sent for and found him with symptoms as detailed above. Believing that he had a case of appendicitis to deal with, and sharing my own faith in free purgation in such cases, he proceeded to give him salines in large and repeated doses. When I made my first visit on Monday I found the boy purging but with no relief to the severe symptoms named.

In talking over the case with Dr. Weaver we concluded that it was not a case of appendicitis for the reason of the existence of the following group of symptoms: that the tumor was present from the very beginning of his attack, did not advance in size, high temperature and quick pulse also existed from the start, his appearance and skin did not indicate the formation of pus, no symptoms of septic involvement present. The purging treatment was continued with the understanding that if the boy's condition was not better by the next day I should be telegraphed for. At noon next day (Tuesday) the boy's condition was considered worse by the family and the doctor—this was 12 noon—then the temperature was 103½°; pulse, weak, from 135-140, and suffering intense pain. At 2.30 P.M. I arrived at the house and found the boy sitting on the side of the bed free from pain, all his symptoms relieved; he had passed from the bowel almost a chamberful of partially digested food. The injury the previous Saturday may have paralyzed to a degree the head of the colon, and greatly aggravated his symptoms. This is not an exceptional case, it is simply one of a very large number of cases which are classed and treated as appendicitis, and claimed as cured of appendicitis by medical treatment.

A careful study of the cases reported as appendicitis and as cured by medication, will convince every experienced and skilled practitioner, whether of surgery or

general medicine, that few of them bear the distinctive marks of genuine appendicitis.

We find the following report of cases in the proceedings of the Philadelphia County Medical Society, 1891, Vol. XII, pages 395–397, reported under the caption, "The Medical Treatment of Appendicitis, with a Report of Five Cases ending in Recovery."

The case of Mr. M. K., who is a prominent and very active literary man in this city, dates from March 24, 1889.

The patient gave me a very intelligent history of his case, which was that there had been a gradual decrease in the evacuations for several weeks, with a great deal of distention and discomfort of the abdomen, and finally obstinate constipation followed. When I first saw him there had been no movement for several days.

He had a tumor and localized pain in the right iliac-fossa. Temperature 103½°, pulse 120, coated tongue, etc.

He was given a hypodermic of morphine and atropine for the pain, which gradually spread over the abdomen as the gas accumulated. Two large doses of castor oil and turpentine were taken without any action. He took calomel, soda and ipecac powders for twelve hours, followed by Hunyadi water, but still there was no movement of the bowels. We then resorted to the enemata of turpentine, laudanum, castor oil, Epsom salts, and hot water given in the knee chest position. These moved the bowels freely and relieved the pain and distention. Turpentine stupes were also used freely.

There was a double inguinal hernia in this case, and to satisfy ourselves that there was no strangulation of the gut, Dr. W. W. Keen was called in consultation, and pronounced the case free from any such complication and confirmed the diagnosis of appendicitis. He suggested pills of colocynth comp. and opium.

The patient made a good recovery and for several weeks took pills of aloin, strychnine, belladonna, cascara and physostigma to relieve the atonic condition of the bowel, and an occasional dose of Hunyadi as he was rather stout and full-blooded.

In July, four months later, this same patient had a recurrence of the trouble while at the seashore, which began, possibly, with a slight tendency to constipation early, but the first the patient complained of was a severe serous diarrhœa with high temperature—104°, pulse 128 (normal 58). Severe pain in the ileo-cæcal region. This attack began before I took up my summer practice at Cape May Point, and Dr. F. E. Stewart, of Wilmington, was called in.

He made a diagnosis of cólliquative diarrhœa, and gave acetate of copper and morphine to check it, and aconite for the fever, but nothing seemed to have any permanent control over the bowels.

Right here in this case, which was my first patient, but his second attack of appendicitis, I learned a very valuable lesson. Here was an obstructed bowel, and nature was trying, by pouring out a very excessive liquid secretion, to flush out the obstruction or foreign matter.

I simply took the cue from nature, and with small, frequently repeated doses of calomel, ipecac and soda, followed by salines accomplished the object, and in less than six hours had the satisfaction of seeing the tumor, which had been in the region of the cæcum, deposited in a commode, which the black, very offensive mass nearly filled. In this attack we used hypodermic injections of morphine for pain and pilocarpine for the high fever and dry skin and tendency to cerebral congestion, as the kidneys were not acting at all freely. There was no vomiting after the first hypodermic, and the patient began at once to take iced champagne and apollinaris, and soon was able to take milk and other liquid food.

In this case no resort was had to rectal enemata, as the bowels were thoroughly cleared out within six hours after the time I first saw the patient, and in three or four days he was attending to his regular business. He took aperient, tonic pills for several months and was requested to use Hunyadi water freely, and rectal injections if the symptoms occurred again. He has had no recurrent attacks and no constipation since.

In the case of Miss S. there were pain and tenderness over the abdomen, which as the case developed, became marked in or over the right iliac-fossa. Instead of dorsal decubitus, the patient sat in a chair with her thighs flexed on the abdomen, and could not lie down until relieved by treatment. There was fever; temperature

102°. There was constipation, nausea, and if I remember correctly, some vomiting, but the latter was not a marked symptom of the case. I did not discover a tumor on abdominal palpitation or vaginal touch, but Dr. David Stewart, who saw the case with me on the second day called my attention to what appeared to be a doughy mass on the right side of the body, on examination per rectum. I must confess that I would not have discovered said mass except my attention had been called particularly to it or in other words I might have had a suspicion of its existence, but it required a finger of more education than mine in feeling for tumors of this nature to make a positive diagnosis.

The treatment suggested consisted of hot turpentine stupes, opium and iodide of mercury; under this she seemed to improve.

From the beginning I recognized the gravity of the case. I advised her to go to the city at once as proper nursing was out of the question situated as she was at the Point. Furthermore, I told her if she got worse an operation might become necessary, and then it would be too late to remove her.

I first saw the case Monday, August 31st, at 6.30 P. M., and found her extremely weak and nervous from the trip from Cape May Point. The temperature was 103½°, pulse 120, abdomen tense, tympanitic, and extremely sensitive. I found a large tumor in the region of the ileo-cæcal valve, intense pain and nausea. There was extreme tenderness over the tumor and abdomen generally, indicating a good deal of general peritonitis. Miss S. was brought to the city by her sister-in-law, and they went into a house where the furniture had just been piled in. There was not even a bed up or any convenience for heating water, so in regard to nursing and environment she did not improve her condition. When I arrived she was on a bed that had been hastily put up.

The sister-in-law, who acted as nurse, got hot water for stupe and enema and the patient had the same treatment, practically, as the boy—the first case reported—except that I entrusted the giving of enemata to the nurse, who proved very intelligent and efficient.

When I called next morning I found the bowels had moved freely several times and, though the patient had had a restless night, she had slept some. The pain and distention were nearly gone and the temperature had fallen to 101°. By Wednesday, September 2d, the temperature was normal and the pain was entirely gone. She began sitting up Wednesday, without my knowledge, and the next Wednesday she went back to the Point. I believe she had a slight recurrence of the pain, inflammation and constipation the week after she got home, but they were controlled by injections, stupes and opium suppositories.

She has enjoyed good health since.

Comment upon these cases is entirely unnecessary. The profession is eminently competent to determine whether or not they were cases of appendicitis.

Antipyrin as a Vesical Analgesic.

Vigneron (*Annales des Maladies des Organes Genito-Urinaries,*) is convinced from its employment in three cases that antipyrin will prove to be a valuable vesical analgesic. Injected into the bladder the remedy is free from harmful effects, even when employed over a protracted period. As an antiseptic the author believes it to be superior to solutions of boric acid. When the solution of antipyrin is allowed to remain in the bladder, it not only relieves the pain but checks spasmodic contractions. A 4 per cent. solution left in the bladder for ten minutes is sufficient to diminish the pain attending subsequent washing or instillation. Antipyrin may be employed in all cases of cystitis in which local treatment induces pain. When the bladder is not distended, two and a half to five drachms of a 4 per cent. solution, left in the bladder for ten minutes, is sufficient. When the bladder is much distended, fifteen to thirty drachms of a 1 or ½ per cent. solution should be injected and allowed to remain in the bladder.

Cocaine as a Means of Stopping the Secretion of Milk.

Dr. Casoli reports several cases in which it was desirable to stop the secretion of milk, on account of the death of the child or for other reasons. To accomplish this he painted the breasts with a five per cent. hydrochlorate of cocaine solution, made with equal parts of water and glycerine. The secretion of milk diminished after the first application, and by the sixth day had ceased altogether.

THE PNEUMATIC CABINET AND ITS THERAPEUTIC USE.*

CHARLES HERWIRSCH PH. M. M.D., PHILA.†

The pneumatic cabinet is an air-tight chamber composed of iron, steel and glass; about 5 feet high, 2 feet wide, 2 feet deep at the top and 3 at the bottom, and large enough for one person to sit in. The front of the upper half is provided with a heavy plate glass window, through which the patient can be seen, in the center of which is a hard rubber breathing faucet, to which a soft rubber tube can be attached, through which the patient may breathe, and medicated sprays may be introduced. On one side there is a mercurial gauge to regulate the degree of rarefaction within the cabinet; and on the other side there is a water gauge to indicate the extent of the respiratory movements as they affect the pressure of air within the cabinet. Ingress and egress is by a heavy air-tight iron door. There is a pair of bellows on the top, which are worked by a lever, and a tube with a valve leading into the cabinet for the purpose of pumping the air out, and to regulate the air pressure within.

When the patient is within the cabinet the air becomes rarefied and the air in the bronchioles and alveoli necessarily expands and is discharged into the larger tubes where there is the least resistance. At the same time the reduced pressure on the pulmonary vessels diminishes their tension, and a free flow of blood from the right heart to the lung and from the left heart to the cutaneous vessels is the result, and the work of the heart is temporarily diminished. (Dr. Von Ruck.) Then the faucet is opened and the heavier air from the outside is allowed to enter. The patient, having the breathing tube in his mouth, is compelled to take a deep, full inspiration, at the same time the bellows are set in motion and the air pumped from the cabinet, or, in other words, rarefied. Now the circulation in the lungs is under the tension of ordinary air-pressure and the necessary result is its depletion. The blood is discharged toward the left heart, whence the left ventricle can easily throw its contents into the circulation with diminished effort. The pumping out of the air from the cabinet rarefies it and the air pressure on the body is diminished; while the heavier air entering from the outside through the breathing tube, is inhaled by the patient, and as the resistance from without is not so great, the inhaled air forces itself into every available space of the lung.

Sanderson says, that the inhalation of compressed air lessens the respiratory movements and number of heart beats, and increases the arterial tension. The effect of this change in the condition of the circulation is to diminish the amount of blood in the veins and auricles, and to relatively increase it in the ventricles. Liebig says, compressed air does not appear to influence materially the production of carbonic air, but it does the absorption of oxygen. Medicated sprays may be introduced and the patient made to inhale them.

From what has been advanced the following has been deducted: The collapsed air cells will be inflated and restored to their normal size and capacity; the blood will be better aërated as more oxygen enters the circulation and, therefore, the nutrition increased; and as the inhalation of compressed air sets the respiratory muscles in motion they must be strengthened. As the smaller and larger tubes are temporarily dilated and the exit of the enclosed air forces the secretions into the larger tubes, expectoration or expulsion of the secretions is at the same time favored. It also follows that the heart muscles are strengthened.

As far back as 1835, experiments have been made with condensed and rarefied air; and again in 1850 and 1857, experiments by this method were made by Tabarie, Bertin, Montpellier and others, by placing patients in reservoirs of compressed or rarefied air. Hauke, of Vienna, made the first portable apparatus, and after him Waldenburg. Since 1885, the

*Read before the North-West Medical Society, February 12, 1895.

†Assistant Medical Department, Philadelphia Polyiclinic, and Physician to Out-patient Department, Rush Hospital.

pneumatic cabinet as above described has been, with few alterations, in use and recommended by men like Dr. H. F. Williams, B. F. Westbrook, Sidney A. Fox, J. T. Whittaken, Carl Von Ruck and others.

For a long time it has been recognized that a high altitude and the breathing of rarefied air is beneficial to consumptives; but, as Dr. Osler says, the rarefaction of air in high altitudes is of benefit in increasing the respiratory movements in pulmonary disease, but brings about in time a condition of dilatation of the air vesicles and a permanent increase in the size of the chest, which is a marked disadvantage when such persons subsequently attempt to reside at the sea level. Now as the patient using the pneumatic cabinet is not compelled to breathe the rarefied or compressed air constantly, but only for a short time, say from ten to thirty minutes each day, and only so long as he derives benefit from it, the danger of permanent dilatation of the air vesicles is avoided.

In phthisis the cabinet is of great value if the disease has not gone too far, but when the lungs have begun to soften and cavities are formed, the cabinet will do no good. I am always guided by the clinical thermometer. If the temperature is not more than 100° F., I allow the patient to remain ten to fifteen minutes in the cabinet every other day, and take his temperature again fifteen minutes after he comes from the cabinet. If there is no rise in the temperature, I put him in the cabinet again on the second day; but should there be an elevation, I try to reduce it by drugs until the fever is brought under control, and then try him again. With medicated sprays I have no experience, but I have seen them highly recommended by different writers. I do not believe it possible, as some of them claim, that a cure can be accomplished by local antiseptic treatment. Benefit can only be derived from the better oxygenation of the blood, the expansion of the whole chest, the strengthening of the heart and the respiratory muscles.

In pleurisy after aspiration, or in dry pleurisy, the cabinet is of undoubted value as it produces complete distension of the lungs and oxygenation of the blood. I have seen cases of pleurisy improve very much under this treatment. In chronic asthma the cabinet will improve the condition wonderfully, but must be continued for a long time. In emphysema compressed air treatment is the only thing from which we can expect any beneficial and permanen tresult. According to Bartholow, "in this condition the object of compressed air is to relieve the breathing by supplying more oxygen and it affects an equalization of the blood in the two systems of redistributing its pressure by retarding the breathing and the action of the heart, the contractions are firmer and the cavities are better emptied. The pressure is transferred from the venous to the arterial system and while the blood on the right side is diminished, on the left it is increased." In chronic bronchitis the cabinet is of very great help to the patient, as it dilates the bronchioles and helps to expel their secretions into the larger tubes, from whence they can be more easily expectorated; and it will, in a comparatively short time, in most cases, cure the patient.

It must not be supposed that when using the cabinet all other medication is omitted; on the contrary judicious medical and hygienic treatment, with the use of the cabinet, must be continued if permanent results are to be expected; and in many cases the result will be improved appetite, increased weight, and reduction of fever.

I will review a few cases in which the cabinet has been used, and the patients have been benefitted by its use.

Mrs. L. G., thirty years of age, native of Ireland, five years in this country, came to me February 21, 1894. Physical examination showed impaired percursion, resonance in left apex extending to third interspace; crepitant râles and roughened inspiration over same area; temperature, 100°; patient very anæmic. The following was given: Arsenious acid gr. $\frac{1}{60}$; strichniæ sulf. gr. $\frac{1}{30}$; ferri reduct., quinine sul. each 1 gr.; in a pill, 4 times a day; codeine gr. $\frac{1}{4}$ for cough as required. She was also allowed to remain in the cabinet 15 minutes every second day. This treatment was continued for two months, only increasing the strichniæ gradually. May 8th, I again examined the patient but could find no râles; percursion was normal; had had no fever since March 19th, and had gained 12 lbs. in weight. I have since been called in to treat her for rheumatism, but she has not complained of any chest trouble.

Mrs. A. W., aged twenty-three, called on me September 24, 1894, with the following symptoms: Physical examination—dullness over left clavicular region extending to fourth interspace; impaired percursion resonance over left scapular region; crepitant, râles over same area; vocal fremitus increased, and roughened inspiration; temperature 100.6°. I gave her strichnine sulph., syr hydrastis acid, syr hypophosphates, phenacetin, 5 grs., at 2 and 7 P.M. On 25th inst., temperature 99.4°. I began with the cabinet and continued this treatment omitting the phenacetin, but using for the cough ext. coco fl., euphorbiæ pill, fl. and codeine, as required, until Nov. 14th, when she reported herself feeling well; temperature normal. On examination I could not hear any râles; dullness had disappeared, but there was still some slight impairment in her left infra-clavicular region. She had gained 4 lbs. in this time.

J. F. L., aged fifteen, a patient in my clinic in the Rush Hospital; first visit Nov. 7, 1894; complaimed of cough every winter for three years with purulent expectoration and coughing spells during the night; dyspnœa and palpitation on slight exertion; appetite poor, symptoms of indigestion. Physical examination, percussion normal, on ascultation sonorous and sibilant, râles over the whole chest; expansion poor. I prescribed strichnine sulf. 1 gr., extr. euphonbiæ fl. ext. coca fl., each five drams; syr. hydriodic acid and syr. hypophosphites, each two oz.; one teaspoonful four times a day and during the night if required; acid mixture after meals. Her weight at this time was 107 pounds. Temp. 99°. Use of cabinet for fifteen minutes every second day. November 19 nocturnal cough had ceased, weight 110½ pounds; continued treatment, increasing the strychnine. December 4, chest examination, negative; no râles heard; gastric catarrh relieved. January 30, 1895, use of the cabinet once a week; no cough; weight 112 pounds.

Miss M. D., eighteen years of age; first visit at Rush Hospital clinic, December 10, 1894; complained of cough since last May; dyspnœa and palpitation on exertion; feverish in the afternoon; night sweats on and off; appetite poor; had not menstruated for sixteen months; very anæmic. Physical examination, dullness in left infraclamcular region; roughened inspiration; temperature 100.2°; weight 91½ pounds. I prescribed a pill of strychnine arsenic, iron, quinine and gentian; phenacetin to reduce temperature. December 19, temperature 99.4°. I put her in the cabinet for ten minutes and continued the above pills, omitting the phenacetin; giving coco and euphorbia for cough. January 25, 1895, she reported much better, dullness had disappeared, temperature remaining at 99°, weight on that date 94½ pounds; appetite better. Is still under treatment.

D. H., aged thirty, colored, and a Mrs. M. J. P., aged forty-six, white, are at the present time under treatment, and as both have a similar history and physical signs, I report only one case. Dry cough, with pain over left side for five or six months; dyspnœa and palpitation on exertion; appetite poor. Over left side friction sounds are heard with impaired vocal primitus and resonsance. Diagnosis: thickening and roughening of pleura on left side with probable adhesions. Both are using the cabinet fifteen minutes every second day, and are taking strychnine and potass. jodi. with good results. In the beginning both patients complained of the pain being very severe after leaving the cabinet, but the pain has since disappeared and both are improving.

In all the above related cases of incipient phthisis, I have made a microscopal examination of the system and have found the bacillus tuberculosis present.

Treatment of Alcoholism by Strychnia Nitrate.

In *Gaillard's Medical Journal*, Breed is quoted as stating, in the *Medical News*, that we have in this drug a remedy that overcomes the desires, with the least effort on the part of the inebriate; a remedy that overcomes the gnawing at the epigastrium, that tones up the nervous system and overcomes mental disturbances, that brings back the appetite, and more than all else, exerting a moral influence upon the patient, supplying that which before was lost, viz., hope, enthusiasm and self-confidence, a bright, youthful expression of the eye, in the stead of the sneaking, apologetic air which is the external badge of moral depravity.

COMMUNICATIONS.

PNEUMONIA.*

DAVID TAGGART, M.D., FRACKVILLE, PA.

When, one year ago, you did me the honor of making me President of this Society, it was with great misgivings as to my ability that I accepted. I relied though on your good nature and trusted that you would be considerate enough to take the will for the deed and overlook many things poorly done, which others might have better done, knowing that my heart would be right if my head was wrong. My administration now passes into history, or that deep, dark, mysterious abyss, "The Archives of the Society;" and, whatever my shortcomings may have been, I can surely make some claim to the spirit of phophecy; for my expectations have been even more than realized, and I now thank you all for the uniform courtesy and consideration with which I have been treated, and for the kindness which has made the task of presiding over your meetings a pleasure.

We can properly congratulate ourselves upon having such a harmonious and pleasant year. Our meetings have all been agreeable and profitable. In this connection I wish to thank the gentlemen who have furnished the papers for the year, as their courtesy in so ably responding to my requests made the matter of supplying mental pabulum very easy for me.

In considering the question of the President's annual address, I am fortunate in the fact that considerable latitude has been allowed in such addresses. I might of course go into an extended résumé of new remedies and new surgical procedures and appliances; but if you don't know as much about the progress of medicine during the past year as I, may the good Lord be merciful and help you and your patients. As for the festive little bacillus which has been the fruitful source of numerous diseases and more numerous papers for the last few years, I must candidly confess to a very slight acquaintance with it personally. Moreover, and it is with a feeling of sadness that I say it, it seems to me that, in spite of laboratory discoveries, in spite of the numerous "antis," warranted to kill the bacillus of this, that, or the other disease, the festive little plant still manages to carry off our patients in nearly the same proportion as years ago, when little or nothing was known about it. Remember now I am speaking only of diseases so-called. When we come to the surgery of the present, contrasted with the surgery of the past, then must we stop and conclude that there is a great deal in the germicidal theories. So let us take hope; rise from our despair; bid the laboratory worker God-speed; and trust that some day we may have the same success with internal antisepsis that has been granted us in the antisepsis of wounds. May that day be nearer than I expect.

I have one course still left open to me, that is to single out one disease and make my few remarks upon that. You will presently be much more ably entertained, so I must make my talk brief. My subject will be "Pneumonia;" not because I know so much about it therapeutically, or expect to present anything new, but for the reason that it is seasonable, and for the further reason that a few years ago I had some very intimate personal relations with it, and the remembrance is still vividly with me. I will not inflict any systematic lecture upon you, who are better posted on the subject than I, but simply give some of my personal and professional experiences, with incidentally a few thoughts if I have any.

Osler defines pneumonia as "An infectious disease characterized by inflammation of the lungs and constitutional disturbances of varying intensity. The fever terminates abruptly by crisis. Secondary infective processes are common. An or-

* President's address before the Schuylkill County Medical Society, January 8, 1895.—From advance sheets Lehigh Valley Med. Mag.

ganism, the diplococcus pneumoniae, is invariably found in the diseased lung." Remember now that I am only giving my own experience; but as to its being an infectious disease, I do not remember ever seeing one case that could be directly traced to another. Although any disease in which there is an active organism at the bottom of the trouble could probably be classed as infectious. As a contagious disease I have no fear, as I have never seen a nurse contract the disease from a patient, have never been able to trace one case to another, and have never seen pneumonia epidemic. Our definition also says that "the fever terminates abruptly by crisis." I have frequently seen the fever so terminate, but doubt very much if such ending is the rule; of late years I have rather thought it to be the exception.

About the history of pneumonia. In almost all cases coming under my personal observation, there has been an initial chill; and I can speak feelingly of that chill—such a sickening, weakening, miserable, unconquerable chill goes with no other disease. After the chill comes that awful pain, lasting sometimes two days or more, but usually and fortunately yielding to treatment sooner. Of course I don't mean to say that all pain leaves that soon, but the sharp, pleuritic pain, which is agonizing at each breath, and the breathing is very rapid at this time, does leave usually in a day or two. After the chill the temperature goes up very rapidly in most cases, but sometimes we find a case with great congestion of lungs and very little rise of temperature; and when you have such cases look out for collapse, heart failure, etc. In fact watch the heart carefully in any case of pneumonia. About this time there will be marked dullness at some parts of one or both lungs, with very often some bloody expectoration. Although the expectoration frequently does not appear until later in the course of the disease. I have seen a few cases run their course with but little expectoration at any time. In cases terminating by crisis the conditions described last for perhaps seven to ten days, when the temperature falls; there is copious expectoration, sometimes almost a hemorrhage; usually considerable diarrhœa, and our patient is speedily on the road to recovery. Again the temperature falls gradually to normal; the expectoration is more moderate in amount; convalescence is more tedious but the ultimate result is still good. Another class of cases are those in which there is no expectoration and the congested and solidified lung must get rid of its unwelcome contents by absorption. These cases are a long time getting well; sometimes they make good recoveries, but frequently there is left a chronic catarrhal pneumonia, or some dullness on percussion, meaning, of course, a solidified spot of lung-tissue which may or may not cause abscesses or other trouble in the future. All our cases do not get well. Some die of general exhaustion, some of exhaustion of the heart; sometimes abscesses form and the case becomes what is commonly known as "galloping consumption." In regard to secondary infective processes, I have seen very little trouble of that kind. Occasionally abscesses have formed in different parts of the body. In my own case I enjoyed a very large, able-bodied abscess on my cheek for some time.

After this brief, imperfect, and desultory history of the disease, a few words concerning treatment will not be amiss. If you see, as you rarely do, your patient in the chill, try, by all means, to break it, as I firmly believe the harder the chill the more internal congestion and future mischief. Alcoholic stimulants I have never seen do much good at this stage; but aromatic spirits of ammonia has served me well in some cases, with plenty of external heat; not by piling covering on the patient and prostrating him still more, but by means of hot water bottles, bags, or even stove plates. Try to restore the normal warmth of the skin and get all the blood to the surface that you possibly can. Friction with a towel, or even the hand, under the covering, frequently aids considerably. If, after the chill, there be much trouble with the breathing, the patient's face becomes blue and there seems, as I have seen once or twice, to be imminent danger of death, really from suffocation, bleeding seems to be urgently called for. I am not at all in favor of bleeding every case of pneumonia, as I have seen advocated by some physicians. Bleeding, I fancy, is only called for in few cases and then, to be of benefit, must be resorted to early and done so thoroughly as to completely relieve the congested lung. I think only able-bodied, full-blooded subjects stand bleeding at all. Full doses of

veratrum viride are very beneficial in some cases. There has been lately a great cry against expectorants in pneumonia; but I am old-fashioned enough still to believe in them, and use them early and late in the case, with full doses of Dovers' powder to relieve pain and promote secretions. Poultices of corn or linseed-meal are sometimes very grateful to the patient, but lately I have seldom employed them, using instead a cotton jacket pretty thick, and a good stimulating liniment. I still consider the hot poultice valuable where there is that horrible pleuritic pain. Cantharidal blisters I never use until after the first week; but have found them serviceable where resolution appears to be delayed. Digitalis must never be forgotten when the pulse is very frequent and heart weak. Alcohol, quinin, and turpentine internally, when the tongue is dry and brown and the typhoid state, with all its dangers, is upon us. Mustard plasters and turpentine stupes are always in order. In those cases where resolution does not occur potassium iodid and other iodin compounds have been very serviceable. In some cases where the lung apparently has cleared, but the nervous system does not recover its tone, and convalescence is protracted, syrup of the hypophosphites has been my friend many times.

I have said nothing as yet about the temperature, as I pay very little attention to it unless it goes to the neighborhood of 103°. I have used antipyrine, well guarded with whisky, in strong subjects, and so guarded have never seen it do any harm. Sometimes good doses of quinin sulfate seem to answer, and again, tincture of aconite root does the work better than anything else.

In conclusion I must apologize for inflicting such a worthless paper upon you and thank you for taking the time to listen to me.

INDIRECT TOXICOLOGICAL ACTION OF STRYCHNIA ILLUSTRATED BY A CASE IN PRACTICE.*

JOHN J. SCOTT, M.D.,† SHREVEPORT, LA.

My attention having been recently called to a similar physiological effect, but in a different line, which I copy further on from the *Northwestern Lancet*, induces me to report this one, as follows:

It is asserted that chickens fed upon a food in which strychnia has been mixed are not affected toxicologically by eating it, and that such is the case with any animated creature containing a gizzard as part of the digestive apparatus.

It is also asserted that hawks and owls that eat of the flesh of chickens thus fed will, however, be poisoned by the flesh thus eaten, provided an adequate amount of the poison be taken in the system.

Others deny the latter assertion and say that such flesh as food is innocuous.

A case in point:

Called to see a stout, able-bodied negro man, aged about thirty years, weight 160 pounds. Saw him about 4 o'clock in the afternoon, August 23, 1888. Was told that he had been suffering for a day or two from chills, followed by slight fever; but that between the paroxysms he had attended to his duties as teamster on the plantation. On the morning of the day of my arrival it was thought he would be able to resume work as usual, but later in the day, about noon, being looked after, he was found to be in an unconscious condition, lying on his pallet in his cabin. On my arrival I found him unconscious, delirious, with left leg and arm in a stiff or rigid condition, while the right foot, the leg being extended, was in constant rocking motion from right to left, resting on the heel. The pulse was thread-like and too frequent to be counted. Temperature was 104½° F. in axilla; pupils dilated. There existed also a tetanic condition, opisthotonos being manifested.

The treatment was directed toward

* Read before the Louisiana State Medical Society, 1894.

† Ex-President Shreveport Medical Society and Member of the Louisiana State Medical Society, etc., etc.

overcoming the tetanoid condition and to restore consciousness. As I learned nothing accurate as to the preliminary symptoms or conditions, it was impossible to arrive at a satisfactory diagnosis.

Suffice it to say all treatment proved unavailing. He died without any modification of the symptoms eighteen hours after I saw him.

Some weeks afterward I accidentally learned from the planter in whose employ he was, that prior to that date he had fed his chickens upon food containing strychnia, given to them with a view of killing the hawks that were depredating upon his fowls. Now, in this little item of intelligence, casually given, I saw and understood in a moment the peculiar symptoms of my patient, which was not so clear then. He certainly exhibited symptoms of strychnia poison, but not pronounced enough to excite one's suspicion at the time.

The inference I now draw, and I am convinced of its truth, is that the peculiar condition of my patient and his death was due to his having partaken too freely of the fowls prepared for the hawks, said fowls not having died from the effects of the strychnia, and yet their flesh so saturated with the poison that it proved fatal to the human system. Undoubtedly one may be affected by partaking of the flesh of an animal that has swallowed any particular medicinal or poisonous agent, while no harm may come to the animal that has swallowed the agent.

Here follows something recently upon the subject, and is recorded as "A Recent Medical Curiosity," that occurred in this way, as given by the *Northwestern Lancet*, viz.:

"An epidemic of priapism is a recent medical curiosity related by a French army surgeon.

"The troops while marching through Northern Africa halted at a station where nearly all the men were seized with prolonged and painful erections, followed by lassitude, dryness of the throat, and finally, in some cases, hæmaturia.

"Investigation showed that the men had eaten freely of frogs killed on the bank of a neighboring stream. Over the stream hung willow and poplar trees, upon whose branches were numerous insects of the family of cantharides.

"These insects fell into the stream, were eaten by the frogs in turn were eaten by the soldiers. The taste of the flesh of the frogs was said to have been in no way affected by the aphrodisiac diet."

This case was reported as presenting a pathologico-physiological question that to my mind is of sufficient signification to interest the profession, and as such is respectfully submitted.

The Therapeutic Value of Ice in Ophthalmic Surgery.

McGillivray (*Ophthalmic Review*) commends the topical employment of cold in ophthalmic surgery. In case of recent injury to the eyeball the eye is bathed with a sublimate solution ($\frac{1}{5000}$), the patient is put to bed and instructed not to open his eyelids, and ice compresses are applied immediately amd continuously. If, after a day or two, no inflammatory reaction has set in the compresses are withheld. In cases attended with inflammation, the application is continued till the process has subsided. Each compress is removed as soon as it begins to lose its cold feeling, and a fresh one is applied.

The Circulatory System in Typhoid Fever.

Dr. F. Billings, in the Chicago *Medical Recorder*, says that while marked anatomical changes in the heart in typhoid fever are not common, yet a slight thickening of the mitral valves and a general muscular flabbiness of the organ, attended with fatty degeneration, are often present.

The heart sounds may at first be clear and normal, but in severe cases the first sound often lessens in strength and duration, and in very low cases it may not be heard at all.

The Treatment of Certain Neuroses by Oxygen Inhalations.

Dr. V. Romaro, according to *La Semaine Medicale*, has found oxygen inhalation very beneficial as an adjuvant in the treatment of so-called function neurosis of a convulsive type. These inhalations diminish the intensity and duration, and sometimes abort the paroxysm, of a convulsive attack. Employed systematically they gradually reduce the number of attacks, improve the general health, and may effect complete recovery. The therapeutical effects of these inhalations are said to be due to the fact that the oxygen counteracts the asphyxial state of the tissues and destroys the ptomaines.

TRANSLATIONS.

THERAPEUTICAL SUGGESTIONS FROM FOREIGN JOURNALS.*

TREATMENT OF PHAGEDENIC CHANCRE.

Dr. E. Braatz (*Centralblatt Fuer Chirurgie*, No. 52, 1894) warmly recommends treating phagedenic chancres with topical applications of cupric sulphate. He employs a solution, for with the powder a crust is formed under which the ulcer continues to progress. The ulcer is cocainized with a 10 per cent. solution, the undermined edges trimmed away and then the ulcer cauterized with a 1:5 solution of the sulphate; compresses are afterwards applied, wet with a 1:5000 solution. These latter at first renewed three times a day, later once a day, and are covered with a strip of rubber protective. As the pain of cauterization often continues some time after the cocaine has ceased to act, a morphine injection may be given either before or after. On account of the obstinate character of the affection the cauterization may be required to be repeated several times before the process is cured.

A PILL FOR SCIATICA.

Dr. W. Richardson (*L'Union Medicale Du Canada*, No. 8, 1894) speaks highly of the following pill in sciatica:

Opium		
Ipecac	āā	grs. ¾
Salicylate soda		grs. vss
Fl. Extr. Cascara, Sagrada		q s

Sufficient for one pill. Make twenty such. One to three a day.

ACUTE BRONCHITIS.

Dr. D. C. Lewinthal (*La Semaine Medicale*, No. 2, 1895), in the treatment of acute bronchitis, has found the following formula efficacious:

Carbonate ammonia			
Salicylate soda	āā 4	o	5j
Elixir paregoric			
Syrup orange peel			
Syrup tolu	āā 30	o	5j
Water	60	o	5ij

A dessertspoonful every three hours.

A SALVE FOR BURNS.

Dr. Starr (*L'Union Medicale Du Canada*, No. 8, 1894) recommends in the treatment of burns the following salve:

Tr. perchloride iron	m liv
Vaseline	5 iv

Applied at once to a superficial burn this salve will calm the pains and prevent the formation of blisters. It is also an excellent dressing for ulcers following deeper burns.

TREATMENT OF MALIGNANT PUSTULE.

Professor Bramann (*La Semaine Medicale*, No. 2, 1895) warmly advocates the local application of mercurial salve as a means of successfully treating malignant pustule. The patient is put to bed, and if a limb has been attacked it is suspended, the region affected is rendered aseptic and a layer of mercurial ointment of twice the officinal strength is applied topically. The diet should be very nutritious and alcohol be administered liberally. No surgical measures should be attempted, as they only favor the extension of the disease. Out of thirteen cases thus treated since 1890 he had no deaths, though there were several that were quite severe.

FROST BITES.

Dr. J. R. Wood (*L'Union Médicale du Canada*, No. 8, 1894) advises the local use of the following salve in frost bites:

Oxide Zinc		grs. lx.
Powdered Camphor		
Powdered Myrrh		" xxx.
Powdered Opium	āā	
Lard		5 j.

CHRONIC CONSTIPATION.

In *La Gazzetta Medica di Roma*, No. 12, 1894, in the treatment of chronic constipation, the following pill is recommended:

Aloes	grs. iv.	
Sulphate Strychnine	"	¼.
Extr. Belladonna	"	j. ¼.
Powdered Ipecac	"	vss.

Sufficient for twelve pills. One each evening.

ASTHMA.

In *L'Union Médicale du Canada*, No. 8, 1894, the following formula is praised in asthma:

Chloral		
Iodide Potash	āā 5	ss.
Syrup Orange Peel	5	vj.
Water	5	vj.

Two to five soupspoonfuls a day.

* In charge of the translator, F. H. Pritchard, M.D.

LOCAL GANGRENE FROM CARBOLIC ACID DRESSINGS.

Dr. Laugier (*Hospitalstidende*, No. 2, 1895), communicates three new cases of gangrene of the fingers from a long continued carbolic acid dressing. In one case the patient has employed a 1 per cent. solution of the carbolate of soda while in the other two the ordinary 2 per cent. solution of the acid was used. None of the patients had any particular inclination to gangrene. He therefore warns against employing ½ per cent. solutions of this antiseptic on the fingers as it may cause gangrene. This is possible not only in children and young persons but also in adults of both sexes without either albuminuria, diabetes, alcoholism or endarteritis being present.

TO REMOVE A PLASTER DRESSING WITH EASE.

Dr. Gigli (*La Semaine Médicale*, No. 3, 1895), in order to facilitate the removal of plaster of paris dressing from limbs proposes the following ingenious plan: After application of the usual thin layer of absorbent cotton around the limb, parchment paper which has been previously moistened is wet and applied. Over this in the direction that the dressing is to be sawed open a good sized string which had been well rubbed with vaseline is laid on and the dressing then applied. The ends of the string are then tied together over the bandage. When in the course of time, the plaster dressing is to be laid off the ends of the cord are untied, one tied to the end of a sufficiently long steel wire which has been closely nicked is drawn through the channel filled by the oiled string and after each end of the wire has been attached to the handles of a chain saw it is drawn to and fro until the plaster has been sawed through. Then the dressing is easily removed.

CHRONIC ALCOHOLISM.

Dr. Zdekauer (*La Semaine Médicale*, No. 7, 1895) recommends in treating chronic alcoholism the following formula:

Satur. solut. chlorine water ...	8	ʒ ij
Decoction althæa.....	155	ʒ iv ℥vj
Simple syrup.....	15	ʒ iv

This will not only ameliorate and cure the gastric disturbances of chronic alcoholism but also will suppress the irresistible desire for alcohol. This is due he thinks to a state of chronic irritation of the nerves of the gastric mucous membrane.

OXIDE OF COPPER AS A TAPE-WORM REMEDY.

Dr. F. Schmidt (*Wiener Medizinische Presse*, No. 3, 1895) has been convinced on himself as well as in four other patients of the efficacy of the oxide of copper as a tape-worm expeller. He employed the following formula.

Black oxide copper.....	6	ʒ jss
Prepared chalk.....	2	gra. xxx
Argilla.....	12	ʒ iij
Glycerine.....	10	ʒ ijss

Sufficient for 120 pills. From eight to twelve a day.

During the first week the patient takes from two pills four times a day; during the second three pills four times a day and abstains from acid drinks and foods. After two weeks a good dose of castor oil is taken. In case of children who cannot swallow pills it may be administered in tablets as follows:

Black oxide copper.....	5	ʒ j ℔
Prepared chalk.....	1	gra. xxx
Carbon., magnes., ää.....		
Gum tragacanth.....	10	ʒ ijss
Glycerine.....	5	ʒ j, ℔
White sugar.....	40	ʒ j, ʒj
Destilled water, q. s.....		

Sufficient for fifty tablets. From two to three a day.

The writer himself took the drug on account of a bothriocephalus; during the first few days he experienced slight pains in the iliac fossa. From the fourth day on he found, in the passages, numerous and greatly altered segments of the worm and in two weeks after a dose of castor oil, the entire worm was expelled. The same result was obtained in the other four patients.

A LINIMENT FOR ECZEMA.

Dr. J. K. Tomory (*La Semaine Medicale*, No. 7, 1895) has found in eczema even in rebellious forms the following liniment of great value as a local application:

Oxide zinc.....	20	ʒ v
Powdered boric acid.....	10	ʒ i jss
Subnitrate bismuth.....	5	ʒ j, ℔
Olive oil.....	85	ʒ iij, ʒv

TREATMENT OF PSEUDO-MEMBRANOUS ENTERITIS.

Dr. A. Mathieu (*Lo Sperimentale*, No. 3, 1895) recognizing constipation as the

principal cause of this affection advises, in mild cases, a regulation of the diet with addition of fruits and vegetables to the list, and the employment of mild purgatives as magnesia, podophylline, cascara sagrada or rectal injections of water to which glycerine has been added or the employment of oil alone; suppositories are also serviceable. In more severe cases he advises rectal injections of olive oil warmed to the temperature of the body. In these cases castor oil in small doses is an excellent laxative as well as olive oil, which may be ordered with an initial dose of three or four teaspoonsful in the morning with increase of the dose to a cupful on the fourth morning. The patient may then rest. Leave it off for four or five days and commence again. Not all patients can bear this treatment. In such Sée advises the employment of senna and hydrastis as follows:

Extr. hydrastis	2-3	o	grs. xxx-xlv
Senna leaves.....	6	o	ʒ jss

Sufficient for thirty pills. One after each meal.

He has also found belladonna of great value for it is both laxative and anodyne.

Intestinal antiseptics are of doubtful efficacy if given by the mouth, but if injected in solution rectally, slowly and gradually, they are of undoubted service. One may begin with one-half a litre and terminate with an injection of two litres after several days. A solution of borax to boiled water, 2-3:1000, is especially commended.

To modify the pathological secretion rectal injections of iodine water or solutions of nitrate of silver may be tried. As to diet all foods that leave much fecal residue are especially forbidden as they favor fermentation in the intestines. In mild cases a diet chiefly vegetable is to be tried, but in the severe ones this would do actual harm. Therefore, one may begin with milk, soups, eggs, mashed potatoes and meat, but in a moderate quantity. Then one may gradually pass over to vegetables and fruits at first boiled and then raw.

In treating the pains which are frequently quite severe, opiates favor constipation and are to be avoided. Instead one may employ hot applications and menthol as follows:

Menthol.....	o	20	grs. iij
Alcohol q. s to dissolve			
Simple syrup.....	25	o	ʒ vj, gtts. xv
Water.....	100	o	ʒ iij, ʒj

Belladonna will not increase the constipation. To improve the general health one will use warm douches, massage, gymnastics, etc.

ACONITE IN CHILDREN'S DISEASES.

Prof. Comby (*Rivista Clinica F. Terapeutica*, No. 1, 1895) on account of the depressive and sedative effects of aconite recommends it in all spasmodic states as asthma, the asthmatic attacks of enlargement of the bronchial glands, in whooping cough and similar states, in stridulous laryngitis, palpitation of the heart and convulsions. It is contraindicated in all states of prostration where respiration is impeded and the heart is about to weaken; therefore, one should not prescribe it in capillary bronchitis, in broncho-pneumonia, pneumonia, in valvular heart affections, in pericarditis and in the collapse of severe forms of infectious diseases.

The alcoholic tincture of the root is especially to be used. In adults one may employ aconitine, yet it is an alcaloid which must be given with great circumspection, administering it in doses of a tenth of a milligram, at regular intervals. It should not be used in children's diseases. The tincture of the root is to be given by the drops and never by the gram and at regular intervals. In a child of two years one may give from five to ten drops; one of five years, twenty drops in twenty-four hours, while up to ten years thirty drops is a proper dose. No great benefit is to be expected from small doses.

PALLIATIVE TREATMENT OF UTERINE CANCER.

Dr. Bowreman-Jesselt (*La Semaine Medicale*, No. 7, 1895) after removal of the necrotic shreds from the cervix and vaginal walls by absorbent cotton and administration of an antiseptic irrigation applies to the whole diseased surface the following solution:

Chromic acid.....	20	o	ʒv
Water...	75	o	ʒij, ʒij, ¾

It should not be allowed to come into contact with the surrounding healthy tissues which are best protected by painting them with a saturated solution of bicarbonate of soda. After application of the chromic acid the vagina is tamponed with iodoform gauze and a morphine and bella-

donna suppository introduced into the rectum. This treatment is repeated three times a day with a preliminary antiseptic irrigation of the vagina. In a few days a great quantity of necrotic tissue will be cast off with subsequent improvement. The vaginal discharge will be less fetid, the pains will decrease in severity, the appetite increase and the general health ameliorate.

TREATMENT OF NOSE-BLEED.

Dr. Lermoyez (*Hospitalstidende,* No. 2, 1895) in slight cases of nose-bleed advises compressing the nose between the thumb and forefinger for ten minutes; if that be insufficient then apply locally a tampon moistened with a 10 per cent. solution of antipyrine which is an excellent hemostatic and much superior to cocaine (1:5) which latter not only has the disadvantage of being toxic but also of being possibly followed by further hemorrhage after the vaso-constrictor action has passed away. It is also to be preferred to solutions of chloride of iron which are strong irritants and may give rise to gangrenous ulcers. In more severe cases a nasal speculum is introduced and the anterior portion of the nose tamponed with fine strips of iodoform gauze four inches in length and one in breadth; these are introduced with fine forceps. As the hemorrhages nearly always arise from the anterior portion of the nasal cavity there is no necessity of tamponing far back. Tamponade of the posterior nares is not only entirely unnecessary but brutal and often dangerous.

PARENCHYMATOUS INJECTIONS OF SALICYLIC ACID IN UTERINE CANCER.

Dr. F. Fafius (*La Semaine Medicale,* No. 8, 1895), in several cases of inoperable cancer of the uterus has obtained very satisfactory results with parenchymatous injections of a 6 per cent. solution of salicylic acid in 60 per cent. alcohol. The hemorrhages ceased as well as the fetid discharge, the pains decreased in severity, the general health decidedly improved and the evolution of the disease was greatly retarded. He employed at each time from one to four ccms. of this alcoholic solution in five or six injections into different parts of the cancerous portion.

PRURITUS OF THE VULVA OF NON-PARASITIC ORIGIN.

In *Le Progrès Médical,* No. 51, 1891, the following preparations are spoken highly of as local applications in vulvar pruritus:

(1) A 1:100 solution of chloral			
(2) Menthol	4	0	3j
Acetic acid	140	0	3iv, 3iij
Alcohol	30	0	3j
Water	150	0	3iv, ¾

LOCAL TREATMENT OF BURNS.

Professor Schwimmer (*Ibid*) recommends in the treatment of burns the following local applications:

Salicylic acid	0	50	grs. viiss
Oxide zinc	10	0	3iiss
Starch	40	0	3j, 3ij
Boric acid	5	0	3j, ¼
Oxide zinc	10	0	3iiss
Vaseline	35	0	3j, grs. xlv
Aristol	10	0	3iiss
Olive oil	20	0	3v
Lanoline	40	0	3j, 3ij
Picric acid	50	0	3j, 3iv, grs. xxx
Distilled water	1000	0	3xxx, 3ij

Hallucinations and Illusions of the Sane.

Inglis (*Am. Lancet*) calls attention to the fact that while "the law has laid much stress upon the phenomena of illusions and hallucinations as being evidences of insanity, it is more and more clearly evident that these phenomena do not necessarily indicate insanity at all. They frequently occur in the sane, however, and play an important part in the deranged mental processes. Still it remains true that perfectly sane people frequently have illusions or hallucinations, or both."

He reports some interesting experiences of his own of hallucinations, largely under control of the will. One of these was a galloping horseman, who could be made to go fast or slow, or multiplied into a whole troop. Another experience was one of a pure beautiful color, without form. When present the color could be changed by effort or will, but could not be voluntarily produced.

Treatment of the Exanthemata.

Armstrong, in the *Medical Magazine,* thus concludes a study of this subject:

1. That antiseptic inunction does not exert any specific power over infectious diseases.

2. That it has but little, if any, power in preventing the spread of infection.

3. That cases treated thus are more subject to complications.

TERMS:—Three Dollars a year in advance. Sent four months on trial for $1.00.

REMITTANCES should be made payable to the Publisher only, and should be made by Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We invite contributions of value to the profession, and if published originally in THE REPORTER such will be paid for at liberal rates, or a limited number of copies of THE REPORTER will be supplied, as the author may elect. Hereafter where reprints are desired writers are requested to make a note of that fact on the first page of the MS., but must order reprints directly from the publisher, who will supply the same at cost rates. Contributors should inclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, APRIL 6, 1895.

EDITORIAL.

CURTAILING A TALE.

The attention of THE REPORTER has been directed to a recent newspaper tilt between a well-known surgeon and teacher of this city, and the President of the S. P. C. A. Just or unjust, the suspicion arises that the controversy has been gotten up to advertise the great surgeon in the daily papers, and one cannot help wondering whence came the commission to speak for the medical profession so dogmatically. Many a good man thinks the childish anti-vivisectors are about as near right as the men who call women liars, and who write popular magazine articles to prove vivisection a blessing by quoting the writer's own wonderful surgical cases. Is there not such a mania as anti-antivivisectors, and such a poor amusement as prodding zoöphiles without occasion?

Probably the most accurate and impartial report of the incident in question is that in the *Public Ledger* for March 15th. We base these remarks upon it. Those who have seen the entire correspondence agree that the artificial warmth and unwarranted publicity on the part of the aggressor well deserved the crushing rebuke elicited. Further notice would be unnecessary were it not that garbled and unfair accounts of the matter appear in some influential medical journals.

Science never gains by the suppression of truth. It is unjust to misrepresent the performance of a plain duty on the part of an honest opponent, or to deride the courage of conviction. It is pusillanimous to assail any without the means for self-defense.

The whole affair reminds one of a "dog-gone" mystery of a former generation.

In a certain quiet neighborhood there are yet living a few who retain vivid impressions of one (call him) Snider and his remarkable dog. Snider was an artisan of more than ordinary ability. He was proud of his skill although he depreciated

the eulogies pronounced over his achievements. His restless genius outgrew the limitations of his daily occupation and he sighed for new worlds to conquer. He determined to renovate nature and give to men some ideas replete with modern improvements. An old acquaintance once said of him: "His ego is eccentric centrifugally to enable centripetal concentration." [We do not know what this may mean unless it be that he devised novel methods for centering upon himself public attention.] "He resembled Cæsar rather than Cæsar's wife—being ambitious, if not above suspicion."

Snider acquired local celebrity as a *savant* by demonstrating, zoölogy to the contrary notwithstanding, the near kinship between the oyster and the elephant through the fundamental characteristic common to both—the inability to climb a tree. He claimed to have made other discoveries equally valuable. His greatness was an essential part of his individuality. Like some peculiar odor or aroma, it was most in evidence when Snider himself was. Like a scent, apart from its source, it could not be produced by any effort of the imagination. Owing to this quality, his fame might have vanished when Snider joined the great majority, had it not been for the tail of his dog.

Regarded as a dog Snider's animal presented no peculiarities save that it was emotional. A thoroughbred mongrel, it was of no particular blood; it enjoyed no advantages of caste; it had no over-weening pride of lineage—it was just dog. Snider conceived the idea that the highest nature of a dog was located in its tail; hence the ultimate purpose of canine life was the development and expansion of this important part of its anatomy. His observations had led to the discovery that all "centers" governing the expressions of canine thought and feeling were situate in the proximal end of the caudal appendage. As the idea grew the dog ceased to wag the tail: the tail wagged the dog. In the progress of evolution the animal was no longer essential and finally disappeared, leaving with the triumphant Snider a dogless tail. Snider exclaimed "Eureka!"; the initiated murmured, "Gloria!"; the ignorant masses ejaculated, "Helen Blazes!" There was no dog; it was all tail.

The present instance forcibly reminds us of the evolution of Snider's dog. Here again the dog was of use solely to provide a support upon which to hinge a tale of abnormal dimensions. So clearly is this purpose made evident when the *entire public* correspondence is considered, that none can doubt the justice and propriety of the scathing rebuke by the President of the S. P. C. A., so courteously administered:

"In conclusion allow me to say that, so far as I can perceive, Dr.——has effected nothing by this correspondence, beyond drawing attention to his own skill and great experience, for which I am quite willing to take his word."

The lady was "in at the death" and, unquestionably, she secured the "brush."

Dry Mouth, or Xerostomia.

Dr. Thomas Harris showed a woman, aged thirty, who had had good health until three or four years ago, when the disease made its appearance. Mouth was absolutely dry, and there was a complete arrest of secretion of all the salivary and buccal glands. There was also a decided enlargement of the parotid glands. The woman was anæmic, but all the organs appeared healthy. There was no disease of the pelvic viscera. Dr. Harris referred to the very few cases of the malady which had been recorded, and especially to two cases of relapsing parotitis recorded by Mr. Jonathan Hutchinson, one of which was associated with a certain amount of dry mouth. Dr. Harris regarded xerostomia as a fuctional nervous affection, and thought that probably the parotid enlargement had a similar cause, and referred to Mr. Stephen Paget's communication on the relation of parotitis to injuries and diseases of the abdominal and pelvic viscera.

SOCIETY REPORTS.

PHILADELPHIA ACADEMY OF SURGERY.

Meeting of February 4, 1895.

Thomas G. Morton, M.D., presented a

CLINICAL NOTE ON A CASE OF CALCULUS IMPACTED IN THE URETHRA, WITH GANGRENE AND RUPTURE OF THE URETHRA; EXTENSIVE EXTRAVASATION OF URINE; RETENTION OF URINE FOR NINE DAYS; OPERATION BY EXTERNAL URETHROTOMY, FOLLOWED BY RECOVERY OF PATIENT.

William R., aged sixteen, a well-grown youth, was admitted into the Pennsylvania Hospital, January 2, 1895, with the following history:

Has had irritability of the bladder, and frequent desire to urinate for a long while, and occasionally noticed a stoppage of the flow while urinating. On December 23d, after such an experience, the interruption became permanent. On the 26th, as he was in great distress, he consulted a physician, who found a stone impacted in the penile urethra about two and a half inches from the meatus. In efforts at extraction the stone crumbled to pieces, but it was removed and the patient states that he then passed about a cupful of blood, but did not empty his bladder. A few hours after the operation the penis and scrotum swelled, forming a tumor which became dark-colored in patches. There was absolute retention of urine. His general condition becoming serious he was brought to the hospital on the ninth day after impaction had occurred.

When admitted into the hospital he was in a condition of shock; he was exceedingly feeble and had septic fever. The penis and scrotum were œdematous and enormously swollen, assuming the form of a dense globular tumor the size of a large orange; the skin of the penis and scrotum was gangrenous. Before coming to the hospital a surgeon had scarified the surface but without affording any relief. The bladder was distended to its full extent and the tumor was the result of extravasation consequent upon rupture of the urethra due to gangrene.

Operation. An incision was made in the median line, extending from the penis through the scrotum, to the perineum, and a large collection of urine was discovered which formed the tumor. The incision divided the scrotum in the middle and exposed the urethra, which was gangrenous to the extent of about two inches; the spot where it had ruptured was in front of the scrotum, evidently where the stone had lodged. The perineal urethra was then opened and the bladder evacuated. A drainage-tube was slipped into the bladder from the wound and a tube was also passed from the meatus. After two weeks both the drainage-tubes were removed. The dead tissues soon separated, leaving a healthy granulating wound. The bladder was evacuated daily with a silver catheter and the further progress of the case to recovery was uneventful. The patient is now presented, a month after the operation, with the wound in a healing condition with the large urethral fistula still open.

The repair of that portion of the urethra which was destroyed may necessitate a plastic operation, especially if it should be found that, in the process of cicatrization, contraction and deformity of the organ is likely to occur.

DISCUSSION.

DR. MORTON: This case is presented partly on account of the unusual character of the accident, but more especially in regard to the length of time absolute retention existed without bladder rupture.

In regard to the closure of the fistula it would seem prudent to wait until the repair now progressing shall show what form of operation may be required.

DR. JOHN H. PACKARD: The only thing to do is to make a perineal section

in the membranous portion of the urethra, and keep the anterior portion completely at rest. When repair has gone as far as it will, then an after-operation can be considered.

DR. WILLARD: The case reminds me of one I saw fifteen or twenty years ago. The man, after gonorrhœa, had a stricture, and he was in the habit of catheterizing himself. One day urination ceased and retention occurred, as he thought, from the stricture. I first saw him on the fourth day of this condition. At this time the scrotum was gangrenous. The whole anterior portion sloughed off and both testicles were bare. Rupture of the urethra had occurred in the prostatic portion, where a stone had lodged, blocking the urethra and causing gangrene. I treated the case by incision in the perineum and scrotum, removing the stones. The wound healed slowly, but without difficulty, and the man lived several years afterward. The incision in that case was two or three inches in length, but did not extend as far forward as in Dr. Morton's case.

DR. W. W. KEEN: The most interesting question here is the restoration of the urethra. Two cases that occurred in my practice some years ago have some bearing upon this. One was a patient in the country, who received an injury of his perineum as the result of jumping and coming down upon the sharp corner of a board, which penetrated the perineum to the depth of two or three inches to the prostate and completely lacerated the urethra. He was brought in from the country, and I saw him on the third day. No urine had been passed. I attempted to make a perineal section, but the tissues could not be recognized. I, therefore, gave up the perineal incision, put him in the Trendelenburg position, and opened the bladder above the pubes. I then performed retrograde catheterization. In performing the perineal operation I had tied a large mass of bleeding tissue, and discovered on making retrograde catheterization that I had included the corpus spongiosum and the urethra in the ligature. I cut the ligature and introduced a silver catheter, and kept it in the urethra for six weeks; the granulation tissue grew around the catheter and restored the urethra completely. Subsequently, by gradual dilatation, I increased the calibre to No. 30, and kept it at this by occasional dilatation, by the sound.

The second case occurred two years ago last summer. A man, in vaulting on his bicycle, missed his aim and landed upon his wheel. He ruptured his urethra without breaking the skin. There was complete retention, and I began a perineal section. After a long search for the urethra I was about to give it up and do a suprapubic operation, when I succeeded in finding the urethra. I left a catheter in for several weeks, and succeeded in re-establishing the calibre of the urethra as in the former patient. It is possible that the same thing might be done here. If the silver catheter is left in place the granulation-tissue might spring up around it and obviate the necessity of a plastic operation. At all events, it would make a subsequent operation less extensive.

DR. PACKARD: About fifteen years ago a boy was brought into the Pennsylvania Hospital, who had fallen across a board and caused rupture of the urethra very close to the bladder. In that case there was no sloughing, simply a rupture at the neck of the bladder, just within the sphincter. He was brought in from the country, and attempts had been made to pass the catheter, but without success. I had him put in the lithotomy position, and made a perineal section. I was in hope of finding the vesicle extremity of the urethra, but that was not possible, and I therefore resorted to the same expedient as that which Dr. Keen had spoken of. I performed suprapubic section and retrograde catheterization. I succeeded in passing a soft instrument through from the penis, and I had no further trouble, and the patient made a good recovery.

DR. HENRY R. WHARTON: I recall having seen four cases of impacted urethral calculus. The first was a boy of four or five years of age, under the care of Dr. Lenox Hodge at the Children's Hospital in this city. He was brought in several days after impaction occurred, and sloughing and urinary infiltration existed. He died in the course of a few days after operation, and it was found at the autopsy that he had typical surgical kidneys. The next case was a child five or six years of age, a patient of Dr. Samuel Ashhurst, in which I helped him operate. The impaction had only existed for twenty-four hours, and there was no gangrene and no

rupture of the urethra. It was found impossible to remove the calculus through the meatus, and an incision was made just behind the stone, and it was taken out. A couple of stitches were used to bring the wound together, but they did not hold well, and the wound healed eventually by granulations. The next case was a man who was brought into the Presbyterian Hospital with retention of urine for twenty-four hours. He had a stone in the urethra at the peno-scrotal junction. I succeeded in grasping the stone with forceps introduced into the urethra, and removed the calculus without difficulty; the patient recovered. The last case was one seen with Dr. Dick; it was a boy four years of age. Retention of the urine had existed for twenty-four hours. I went prepared to operate, but just before I reached the house I was informed that he had passed the stone, which I now present, and there was no further trouble. In all the cases I have seen the impaction has occurred at the junction of the penis with the scrotum, which seems a favorite place for the stone to be arrested in its passage. With regard to the subsequent treatment of the case shown by Dr. Morton, it appears to me to be better to wait to see how much will remain after cicatrization is complete. In such a case I would make a perineal section before attempting to reconstruct the urethra. The condition is more favorable than hypospadias, because a considerable part of the anterior urethra is present.

W. W. Keen, M.D., discusses a paper on the

AMPUTATION OF THE ENTIRE UPPER EXTREMITY (INCLUDING THE CLAVICLE AND SCAPULA) FOR SARCOMA FOLLOWING FRACTURE OF THE CLAVICLE.

E. S., aged twenty-one years, first consulted me early in December, 1894. In May, 1893, he broke his left collar-bone by a fall. In June, 1894, a tumor appeared at this point, which together with one-and-one-half inches of the clavicle, was soon afterwards removed by Dr. Stout, of California. The tumor, however, immediately reappeared, and has grown rapidly ever since. For the last month he has been under the care of Dr. Coley, of New York, for treatment by the erysipelas and prodigiosus toxins, but without obvious benefit. At present there is a large tumor extending from the shoulder to the base of the neck and attatched to both clavicle and scapula. It reaches to within two inches of the inner end of the clavicle. I deemed it, however, still possibly operable, because it did not seem to be infiltrating but encapulated. This conclusion I based upon two grounds: First, that the tumor seemed to be very movable with the shoulder, and, secondly, there was not the slightest edema of the arm. This convinced me that the vessels, and especially the veins, were not yet involved. I told him frankly that it was uncertain whether I could remove the growth, but that if he desired it I would attempt the operation. Since he could at least be no worse off by its removal, and even if death followed it would relieve him from weeks on even months of great suffering. He and his family readily consented to operation.

The tumor was ulcerated at two points, and the skin was branny and thick. The conditions, therefore, were unfavorable to a thorough asepsis, but the parts were as thoroughly disinfected as possible. My plan was to adopt the method as described in my paper before the American Surgical Association in May, 1894 (*Transactions American Surgical Association*, 1894, p. 55, and *American Jounral of the Medical Sciences*, June, 1894), namely, to make one incision at the inner border of the tumor with its centre at the clavicle, and another at a right angle along the line of the clavicle down to the bone, to dissect these flaps, and by drawing away the tumor to uncover as much of the clavicle as possible, removing as much of the inner end as I could, and then search for the vessels. If I found that they could be easily ligated I should then proceed to remove the entire upper extremity. If however, the vessels could not be reached that I should then close the wound and abandon the operation. Professor Brinton and Hearn, after careful examination of the patient, both agreed with me as to the advisability of attempting it. Accordingly, he entered the Jefferson Medical College Hospital on December 24th. His temperature was then 100°. His pain

was so severe and constant as to deprive him of much sleep. He was, however, generally in very fair health, though not strong.

Operation, December 26, 1894. The plan outlined above was carried out. I removed two-and-one-half inches of the inner end of the clavicle. Drawing the tumor away, and scraping it from the clavicle enabled me to remove much more than I had expected. I then sought for the vessels, and was so fortunate as to be able to dissect them loose and follow them down to the upper border of the pectoralis minor. At no point did I find the tissues under the great pectoral involved. In order to tie the vessels at so low a point I had gradually extended my vertical incision nearly to the axilla, and having secured the vessels I then decided to proceed with the amputation. It was evident that removing the tumor would remove so large a portion of the skin that it would be impossible to approximate the edges. Accordingly, I determined to carry my incision down on the arm nearly to the elbow and to dissect a flap of skin which was healthy from the inside of the arm, and turn it upward so that the lowest end near the elbow would become the highest when turned upward on the neck. In dissecting the arm loose I removed the larger part of both the pectoral muscle and had to tie a number of smaller vessels. The posterior incision was now made, cutting as wide of the tumor as was possible, the incision passing nearly along the posterior border of the scapula. The separation of the extremity was now readily effected, and a moderate number of vessels ligated. After renewed disinfection of the large surface it was closed. The elbow flap was turned upward on the neck and enabled me to cover the entire raw surface by skin without any tension. As the skin of the inner side of the arm near the elbow derived its nourishment not from the branches of the vessels from the axilla but lower down from the arm, its transplantation was analogous to skin grafting, and I regretted afterward that I had not been very careful to dissect from its inner surface all the fatty tissue of which only a little, however, was left. At four points I inserted between the stitches small portions of iodoform gauze to act as drains.

The patient was put to bed with apparently little shock, his temperature being 97.6°, though the operation had lasted nearly two hours. His recovery was rapid and satisfactory, the temperature only rising once to over 100°. On the sixth day he was out of bed. A small portion of the posterior edge of the flap from the arm sloughed. But for this he would have been entirely well within ten days.

Remarks: At the meeting of the American Surgical Association in Washington, May 29, 1894, I read a paper on "Amputation of the Entire Upper Extremity, Including the Scapula and Clavicle, and of the Arm at the Shoulder-joint, with Special Reference to Methods of Controling Hemorrhage." The key of the whole situation, as I there pointed out, is very clearly the control of the hemorrhage. In the present case operation had been declined by several surgeons on the ground that the disease was too extensive for a successful operation. I was convinced, however, that the vessels were not yet invaded, because there was no edema of the arm, and, also, on moving the tumor in various directions it seemed to me not to be so adherent as to prevent my getting under it and obtaining access to the vessels. My impression was that I would be obliged to ligate the subclavian vessels in the first part of their course; but, after resecting the clavicle and tearing through the tissues behind it, one of my assistants was able to drag the tumor outward, and this gave me an unexpectedly easy access to the vessels, which I was able to follow down to the first part of the axillary artery and tie them there. I was the more anxious to tie them low down, because I foresaw that it would be needful to utilize the skin of the inner arm to fill the gap left by the removal of the tumor, Had this not been done a very large raw surface would have been left, either to granulate or to be covered by skin grafting. I very much feared that even so high a ligation as the first part of the axillary would be followed by some sloughing of the flap of the skin, but fortunately, only the posterior edge of this flap sloughed to a small extent and delayed the healing for about ten days or two weeks.

I was unable to follow the typical method of Berger or that of Treves, but was obliged literally to "cut my coat according to my cloth." The branch of the brachial plexus of nerves going to the

great pectoral was very easily seen and was a very good guide to the vessels. Each vessel was tied with two ligatures of silk, and the vessel divided between them; the artery was tied first, in order to diminish the amount of blood in the vein, and I found this way very advantageous. The amount of blood lost was not very great, and the shock of the patient was very moderate. He made a most gratifying, uninterrupted recovery. Later, when the slough had separated, a few stitches were inserted to draw the granulating surface together.

He weighs less by six pounds than when he entered the hospital, but the portion removed was about ten pounds, so that he has gained about four pounds. The operation was done the day after Christmas, that is, forty-one days ago. This is the second operation of this character that I have done; in both the scar was about the same, although in the former case, a young lady, the tumor was not so large. There was very little shock in either case, although the operation lasted two hours. The first patient was out of bed in five days; this patient was out of bed in six days. The shock was much less than I expected from such an extensive dissection. The patient is now in good health.

John H. Packard, M.D., presented a paper

ON A MODIFICATION OF THE "INVAGINATION" METHOD OF OPERATING FOR THE RADICAL CURE OF HERNIA.

I think it can hardly be necessary to enter into any argument as to the desirableness of effecting the radical cure of hernia in every case where it is possible. My own experience is that there is great difficulty in getting trusses properly fitted as well as in having them properly applied by the patients. Yet a truss badly made or wrongly put on, may be worse than useless; it may cause suffering, and even danger to life.

A radical cure can be accomplished only in one way: by doing away with the sac as such; by obliterating the tube of peritoneum, like a glove-finger, through which the descent of bowel or of omentum takes place. This is the object aimed at in all the proposed procedures, which are very many. Sédillot, in the edition of his *Medicine Operatoire* published in 1855, enumerated twenty-five, and his list was not then complete. The number has been very largely increased since that time, and especially, of course, since by the introduction and general adoption of antiseptic methods, the dangers of such interference have been in a great measure set aside. Modern surgeons have suggested and put in practice much bolder modes of dealing with the problem than could formerly have been employed. By some, as Banks and McBurney, the sac is ligated and cut off as high up as possible. Barker cuts it off at the external ring and carries the stump up to be sutured into the internal ring. Ball twists it up and applies an intercolumnar suture. McEwen and Bishop crumple it up by means of "drawing-string" sutures. Bassini's and Halsted's plans are to make a new canal and a new ring. Landerer makes a plastic operation, transplanting one of the columns of the external ring. Kocher carries the sac away from its position, angulating it twice, bringing it out through an artificial opening in the tendon of the external oblique muscle, and then twisting it.

I do not propose to discuss these various methods, but venture to suggest another plan by which the hernial canal can be closed, I believe securely and permanently, and the object accomplished in a simple way.

I think it may be laid down as a sound rule of surgery, that in all operations there should be as little sacrifice and as little disturbance of the parts as possible, consistently with the attainment of the desired end.

A recent writer says that there are two requisites for an operation for the radical cure of hernia.

"1 Complete elimination of the peritoneal funnel, of which no trace must be left in the canal.

2. The firmest union of the rent in the fibrous layers of the abdominal wall that can be obtained."

He then states that "a proper operation requires the hernial canal to be laid open throughout its whole length up to the level of the internal ring, and the neck of the sac and the peritoneum beyond the internal ring to be completely loosened and dissected free for some distance beyond. Thereafter the walls of the canal must be accurately sutured and brought in the closest possible apposition." In other

words, he would first lay open the abdominal wall, and then close the rent as firmly as possible. But would it not be better to avoid making the rent unless it is absolutely necessary to do so?

I think we can do away with the sac as such without any destruction of its tissues, not eliminating it or laying it open, but simply making use of it, converting part of it into a solid plug, and fastening it into the canal at its inner end, sacrificing nothing. Such invagination of the isolated sac is the essential principle of the procedure which I wish now to describe.

It will be remembered that there were in vogue many years ago a number of invagination methods. Of these perhaps the best known was that devised by Gerdy, but modified by Wützer, and generally attributed to him. All these methods consisted in pushing up the sac along with a considerable amount of the surrounding tissue; and my belief is that to the want of isolation of the sac, and the consequent drag upon it, many failures in cases at first promising should be attributed.

Some successes were, however, attained. I operated in 1863, by a method substantially that of Wützer, upon a young man who was desirous of entering the U. S. Navy, but was prevented by the fact that he had a right inguino-scrotal hernia. He afterward gained his appointment and three years later was doing duty as a third assistant enginneer, the rupture giving him no trouble. Two other cases, on which I operated in the same way at about the some time, passed out of my observation before the results could be determined. And the risks and uncertainties of all such procedures were then so great that it seemed imprudent to undertake them unless in exceptional instances.

I have already said that the method which I wish now to describe consists essentially in the invagination of the isolated sac. No one feature of it, I believe, is entirely new; but as a whole it has not to my knowledge been proposed by anyone else.

I expose the hernia by a curved incision, describing a semi-circular flap of ample size. This I do also in operating for strangulated hernia, as it carries the cicatrix away from the seat of trouble, which is afterward covered in by sound skin. (I have several times noticed, however, that in the final healing the scar is drawn over so as to form a straight line between its two extremities.)

The sac being laid bare, is isolated from the external ring down to its tip. Sometimes it is better to empty it during this process, which may often be accomplished by tearing with the fingers. Bassini's advice, to begin the isolation at the ring and to proceed downward, is, I think, generally to be followed.

In order to secure control of the empty sac I now pass a silk thread through its wall at either side; the two ends of each are left long, and caught in hœmostatic forceps.

With the forefinger of the left hand the tip of the sac is now inverted and pushed up as far as the internal ring, or as near it as possible.

Next a slightly curved needle, with an eye near the point, and armed with a thoroughly sterilized silk thread, is passed up along the finger as a guide, to be pushed out at one side of the tip through the tendon of the oblique muscle. One end of the thread being caught, the needle is withdrawn slightly, and again pushed through the tendon at the other side of the tip. The other end of the silk thread is now detatched from the needle, which is wholly withdrawn, and the two ends, left slack, are caught together in a hæmostatic forceps.

Now, by means of the two lateral threads, and by grasping in the fingers, the doubled sac is drawn down carefully, and with a small curved needle a fine silk suture is passed through it from side to side from below upward as far as possible, and then from above downward, so that its two ends, when drawn tight, will crumple up the sac into a solid mass. These ends are tied and cut off short.

The lateral threads are now removed, and the other silk thread is drawn up tight, pulling the plug formed of the sac into place at the internal ring; its two ends are tied on the outer surface of the tendon of the external oblique, and cut off short. The skin-flap is laid over in place again, the wound closed by sutures, and the ordinary antiseptic dressings applied.

Until the wound is completely healed the patient is kept in bed. I have not put a truss on any of the patients recently subjected to this operation, but have cautioned them against making any muscular effort likely to bring undue stress

upon the parts until time enough has elapsed for their consolidation.

As to the ultimate results of this operation I have no cases of sufficient duration to enable me to speak positively. A man, aged twenty-two years, operated on October 24th, is present for your examination this evening; he does full work as an orderly at the Pennsylvania Hospital without either truss or discomfort. To my disappointment, a boy, aged twelve years, operated on December 12th, has failed to be here; there is no sign of yielding of the plug, though he is running about as heedlessly as any boy of his age. A man, aged forty-nine years, operated on at the same time, seems also to be completely relieved. On January 10th I operated on a man aged fifty-four years, at St. Joseph's Hospital; he has since had a severe bronchitis, but his hernia seems entirely controlled, and he is now going about freely. Another man, aged thirty-two years, in the Pennsylvania Hospital, operated on January 7th, is still under treatment.

Of four other cases, including the first one, operated on in September, 1890, I will not speak as they passed completely out of my knowledge too early for the results to be determined.

I am well aware that my array of cases is very small, but the first two above mentioned and the fourth afforded pretty severe tests of the efficiency of the closure of the canal. I offer the method as one which seems to me sound in principle and promising well; moreover, in case of its failure, the parts are in condition for the repetition of this procedure or for the adoption of any other that may commend itself.

Of course, there must be an exercise of judgment as to the suitableness of any mode of operation in any given case. I think there would be difficulty in adopting the one now described in cases of congenital hernia; and whenever for any reason the sac must be extensively opened it would have to be carefully sutured before invaginating it. And I believe that it might not answer well if the canal and internal ring were very wide.

DISCUSSION.

DR. KEEN: It seems to me that in some respects Dr. Packard has made a decided improvement in operating for the radical cure. It is directly in the line of recent work in the field of general surgery, which has lately been discussed by Mr. Chiene in a paper on "The Flap Method in Surgery," in which it is shown that the introduction of this method into cerebral surgery by Mr. Victor Horsley was a great improvement. It seems to me, by using this method, that we gain additional strength in the cicatrix.

The proposed method does not seem to me to secure the internal ring as well as a suture applied high up and within the internal ring, so as to close it, which I always do. In the second place there was nothing said about suturing the abdominal wall and without an incision in the abdominal wall it is difficult to locate the internal ring accurately. If this is not closed there will be left a tube beyond the bite of the ligature. There must also be an opening in the belly wall through which the spermatic cord passes, which is not narrowed in this operation, which would permit recurrence of the hernia. The case presented is too recent to permit any conclusion as to the ultimate result, and in the one of four years' standing the result is unknown. I must take exception to Dr. Packard's statement that the Bassini or the Halsted operation is too difficult for most general practitioners. It does not require a good knowledge of anatomy, but unless a man is a good anatomist he should not operate for hernia.

DR. PACKARD: In reply to the first point, with regard to not closing the internal ring, I would say that in many cases the internal ring is reached if the operator pushes his forefinger as far up as he can. I suppose that in some cases where the canal is long one can hardly be perfectly sure that he has reached the end of it. When the ligatures are tightened they draw up the mass which is held in the canal and make just at the internal ring an exceedingly firm plug, which can be felt from the outside for a week or two after the operation and which gradually subsides. This plug fills up the canal, except the lower portion, which is entirely open, and the dimple behind the peritoneum, where the constituents of the cord come out. Of course, there may be a dimple left at the inguinal ring; but, unless one opens the abdomen and operates from within, one cannot be sure that there is a projection instead of a dimple. The only difficulty is in getting the end

of the sac pushed up and suturing it to the internal ring; otherwise it is a very simple operation, and the results have been so far satisfactory. I should be very glad to have it tried by other surgeons.

DR. WHARTON: What is the relation of the plug to the suture?

DR. PACKARD (Making a diagram): If we represent the pillars of the ring, leaving space for the canal, the sac is inverted and pushed up as far as the internal ring, the inverted sac is then stitched to the sides of the ring and by drawing the suture tight the plug is drawn up the canal formed of the sac to the internal ring.

DR. KEEN: If the abdominal wall is not incised as in Halsted and Bassini's operations, but only the finger is inserted in the canal, how can the operator tell, when he introduces the suture and carries the needle backward and forward, that he is closing the canal exactly up to the internal ring?

DR. PACKARD: By pushing his finger well up in the tube, using a Baker Brown needle, and introducing it along his finger to the end of the tube and pushing it out at the side, he can always reach the end of the canal. The suture which is carried backward and forward has nothing to do with the internal ring; it is intended merely to crumple up the doubled sac into a solid mass to constitute the plug.

DR. KEEN: It seems to me that the difficulty is that without splitting the abdominal wall up to the point where he is going to suture, Dr. Packard cannot get his first suture as high as he represents in his diagram, and then he leaves the upper part of the canal open. I would also ask if the plug may not slough? In the Macewen operation, if the hernia be large, the sac may slough, as I have seen in one case. I therefore would not use the Macewen operation for large herniæ.

DR. PACKARD: I agree with Dr. Keen that in large herniæ operation is not advisable; better leave such to a truss than do any operation. Now, to reply to his criticism, I find that when these sutures are applied as described, the mass goes up to the internal ring, or right up to the suture, and remains there. I will not pretend to say that in every case it goes clear to the internal ring; but it does fill the lumen of the canal, and, as stated above, has in several cases withstood severe tests.

W. W. Keen, M.D., presented a paper on the

EXTENSIVE THORACOPLASY BY SCHEDE'S METHOD.

A. K. S., of Blacklick Station, Indiana County, Pa., aged thirty years, was admitted to the Jefferson Hospital, March 11, 1894.

The family history is negative. He had all the usual children's diseases, and four years ago, after a severe attack of enteritis. Twelve years ago, after a severe attack of pneumonia lasting six weeks, left-sided pleurisy set in. Two months later a small incision was made, between the sixth and seventh ribs just to the left of the nipple line, and a drainage-tube was introduced. For fourteen months a small amount of pus escaped through the opening after removal of the drainage-tube. Then the opening was enlarged, and over two quarts of pus was then evacuated in twelve hours. A large drainage tube was then inserted. He immediately began to gain in weight, and says that he gained thirteen pounds in the first fourteen days. His weight had been as low as ninety pounds, though he is six feet tall.

Status præsens: Weight, 145 pounds; appetite good, and he feels very well; no bloody expectoration. Between the sixth and seventh ribs, just to the left of the nipple line is a drainage-tube which he has worn continuously for nearly eleven years. About half an ounce of pus escapes from it in twenty-four hours. Occasionally it is blood-stained, and he has had an even greater amount of blood escape when excited by coughing or by the introduction of a new tube, sometimes losing over a half pint of blood. The whole left chest is much sunken in.

Operation March 14, 1894. A vertical incision was made just outside the line of the nipple, and about two inches of the seventh and eighth ribs were resected, exposing the upper surface of the diaphragm. Starting from the opening in the chest cavity, it was with the greatest possible difficulty that I could resect the ribs, since they were absolutely in contact as the result of the deformity of his chest. The pleura was also over an inch in thickness, which made the thickness of the chest-wall about two inches, and therefore very rigid.

In addition to this the left lung was

firmly bound down and so contracted that there was practically little lung tissue in use. Hence, as his respiration was almost confined to the right lung, I had to watch the ether very carefully, and by the time that I had resected these two ribs it was very evident that the operation should be terminated, and anything further left for a future date.

The wound was packed with iodoform gauze. His highest temperature after the operation was 99.8°. The cavity of the chest was washed out with pyoktanin, boric acid, sublimate solution, etc., at different times.

He left the hospital May 28, 1894, in much better health and with little annoyance from the large cavity remaining in the chest, from which the discharge was comparatively slight. He is to return for a second operation.

Second operation, Jefferson Hospital, June 30, 1894. Examination by a long probe showed that the cavity of the pleura was very large and extended to a level with the clavicle. My intention was to resect as much of the chest-wall as possible. I was obliged to be extremely careful of the anesthetic, as I had been in the previous operation, lest, having a little more than one useful lung, the anesthetic and the operation together might prove fatal. I made a vertical incision from the clavicle to the still-existing opening into the chest cavity, followed by two horizontal incisions at each end of the first. I then dissected the soft parts from the ribs internally to within an inch of the left border of the sternum, and externally to a point an inch posterior to the anterior border of the scapula. Then, guiding a large pair of bone forceps by my finger, and starting from the existing opening, I cut ribs, muscles, pleura vessels and nerves, *i. e.*, the entire thickness of the chest-wall up to and including the second rib, then, starting again from the prior opening outwardly to a point a little in front of the inferior angle of the scapula skirting the upper surface of the diaphragm, then from this point directly upward, and again horizontally on a level with the second rib. Most of this large mass, an account of its thickness, had to be removed piecemeal, part of it in two or three large pieces. The size of the portion removed was approximately eight inches vertically by five inches horizontally. A number of the larger intercostal arteries bled, but were seized with hemostatic forceps, and finally, even without ligation, on the application of very hot water, ceased bleeding. The inner wall of the cavity was found to be enormously thickened visceral pleura and pericardium, stretching like a vertical diaphragm from front to back at a point about an inch external to the left border of the sternum. This was thoroughly curetted and swabbed. The flaps were then laid directly upon the thickened pleura and pericardium and sutured in place. His recovery was without incident, though slow. The reaction was very moderate.

October 6, 1894. He came to the hospital again to-day to see me, and I found the only remnant of the wound was a cavity about as thick as a lead pencil and an inch-and-a quarter deep. With light packing this will soon heal. His chest is very much deformed from falling in of the wall, but the cavity is entirely obliterated. His general health is excellent.

The opening closed entirely about the middle of November, and he is present this evening for your inspection.

REMARKS. The present is by far the most extensive resection of the wall of the thorax that I have ever done. The first operation was particularly preliminary, simply to gain access to the cavity of the pleura, and had to be terminated somewhat abruptly on account of the difficulty of the etherization. The second operation was attended with less difficulty from the anesthetic, and was fully carried out.

The operation which I made I have subsequently found has been described by Schede as a modification of Estlander's operation, or rather, perhaps, in suitable cases as a substitute for it. In the present case Estlander's operation would have been useless, on account of the immensely thickened pleura.

Schede makes a large, semi-circular flap with its base at the second rib, its curve beginning on the front of the thorax and sweeping downward and backward in a larger part of one-half of the thorax. In my own case, the soft parts were dissected from the ribs by a vertical incision with two horizontal incisions at the upper and lower ends of the first, making an L. It seems to be equally satisfactory with that of Schede.

The case with which the operation was

done, and the admirable result, commend it to me very strongly. Nothing less radical would have effected a cure. The vessels were controlled without the slightest difficulty by hemostatic forceps, not even a single one requiring ligation.

His present condition eight months after the second operation, is curious. The thoracic wall, where its entire thickness has been removed, is as firm and resistant as if the ribs had never been removed. This may be due to two causes: First, the tension of the soft parts of the old chest-wall, which stretch like a drum-head from the anterior to the posterior border of the opening I made; second, the thickened pleura and pericardium on the median surface of the old empyemic cavity, furnish a very firm resistant base on which the flap presumably rests. I intentionally use the word "presumably," for on percussion the entire left chest is resonant, and even tympanitic, as if there were a pleural cavity still existing. Were this really the case there would certainly, however, be a considerable amount of pus secreted, and this can scarcely be the fact, in view of the healing of the cavity for so long a time. Moreover, in October last, when I examined him with a probe, no cavity, but only a small sinus existed. The lung can hardly have expanded enough to fill the cavity, for a pleura an inch thick can scarcely have been absorbed to such an extent as to allow of such expansion. The respiratory murmur, however, is heard for a inch external to the left border of the sternum.

The posterior portion of the ribs form a marked projecting ridge near the posterior axillary line. It looks as if the resections were much less extensive than I have described, but this is due to a lateral curvature of the spine to the left, thus making the spinal part of the ribs much more prominent than would otherwise be the case. The movements of the arm are perfectly free, the removal of the greater part of both pectoral muscles having had no restraining effect upon this free shoulder motion.

The apex beat of the heart is in the normal situation.

He has not gained in weight very much, but his general health is excellent.

A few days after he was shown to the Society the wound broke open again and discharged a small quantity of pus. I then did a third operation, removing some more of the chest wall at the upper posterior angle. I found a cavity 3½ inches long and as thick as the thumb. This is now (March 27th) nearly obliterated by granulation tissue. His general health is reëstablished, and he is now, I believe, entirely cured.

De Forest Willard, M.D., presented a paper on the

ADVANTAGES OF AMPUTATION THROUGH THE KNEE-JOINT AND THE AVOIDANCE OF THE TOURNIQUET WHEN THE VESSELS ARE ATHEROMATOUS.

The disadvantages of the use of the tourniquet when the vessels are atheramatous are obvious. The constriction causes not only minute fissures in the walls of the vessels, but it may even fracture them, and in either case it tends to develop arteritis, subsequent loss of vitality in the flaps, and secondary gangrene. At the same time the cases presenting this condition are frequently old and feeble persons who are seriously exhausted by the local condition of gangrene, presenting other evidences of obstructed vessels, and can illy afford any loss of blood.

Gangrene occurs most frequently in the the feet and legs, and for such condition amputation in the neighborhood of the knee-joint or at the thigh, is advisable since, after leg amputations the diseased conditions frequently return.

Amputation through the knee-joint can be performed with less hemorrhage than at any other portion of the limb, since, in the neighborhood of the knee, all the vessels in front are small and can be readily caught with hæmostats as the anterior skin-flap is cut. The tendo-patellæ, the lateral and posterior ligaments can all be divided without serious hemorrhage. We then have the limb hanging by the posterior bridge of soft tissues, which bridge contains the large vessels, and can be easily caught by the fingers of an assistant; in fact, it is now a perfectly simple matter to expose the popliteal artery and to test its pulsation to discover whether it is actually previous, then to expose it just enough to carry around it a bundle of catgut ligatures, four or five, which ligatures are tied just sufficiently tight to bring the

inner coats of the vessels together and not to crush them.

Sometimes the popliteal artery will be found thoroughly plugged, necessitating the working up in the posterior flap for a considerable distance before a previous vessel will be found.

The popliteal having been tied, the flap is firmly grasped to control the smaller arterial branches, and the posterior flap quickly cut of the desired length. The operation is practically bloodless.

Should the artery be impervious, it may necessitate an amputation higher than the joint itself. The tissues now can be pushed back, the periosteum divided above the condyles, and stripped back from the femur to the desired distance without loss of blood and without injury to the soft tissues. The femur is then divided opposite the point of ligation and the wound dressed antiseptically.

By thus stripping back the tissues subperiostically an amputation in the lower third of the thigh can be performed with but little lose of blood and without injury to the vessels by any form of constricting band. It is a plan equally well adapted to traumatic cases with atheromatous vessels.

The knee-joint region should then be the site of election. A broad ligature loosely tied is the best.

DISCUSSION.

DR. L. W. STEINBACH: I thought that it was an accepted method among surgeons not to use the tourniquet in cases of atheroma. While agreeing, therefore, with Dr. Willard, it seems novel that he should call attention to it. I have used the board band of the Esmarch apparatus in amputations of the leg for gangrene. In a recent case I had considerable difficulty in finding contracted vessels, but the patients made a good recovery. In one case I did not even use the precaution of employing the Esmarch, and had the vessels compressed by the fingers of an assistant, and the patient recovered.

DR. WILLARD: The point which I intended to accentuate was that an amputation could be made through the knee-joint without loss of blood, even though no constricting band was used.

H. R. Wharton, M.D., presented a paper on the

INJURIES OF THE LOWER EXTREMITIES REQUIRING AMPUTATION OF THE RIGHT LEG AND EXCISION OF THE LEFT OS CALCIS.

Jos. B., aged fifty-eight years, was admitted to the Methodist Hospital in April, 1894, with an extensive compound comminuted fracture of the bones of the right leg, and a lacerated wound of the sole of the left foot with extensive comminution of the os calcis and separation of the attachment of the tendo Achillis.

The patient had received these injuries while at his work, the band of his trousers being caught upon a shaft which was making 120 revolutions per minute; he was wrapped around the shafting, and at each revolution of the shaft his feet and legs were struck against the wooden joists near the shafting. On examination of the right leg it was found that the foot and lower portion of the leg were completely crushed, and an amputation was made through the middle third of the leg.

Upon examination of the left foot it was found that a flap consisting of part of the sole of the foot and heel, including the plantar fascia, was turned forward, the os calcis was extensively comminuted, and the tendo Achillis was torn loose from its attachment, and its extremity was torn into shreds.

I removed the os calcis completely, and having trimmed off the shreds from the tendo Achillis, sutured it to the posterior portion of the plantar fascia. It was noticed during the operation that all the arteries were very atheromatous.

The patient did well after the operation, and with the exception of a small patch of gangrene which occurred upon one of the flaps of the amputation, and some sloughing of part of the heel of the left foot, which delayed the healing of the wounds, his recovery was uneventful. I present him this evening to show how useful a foot he has, even after excision of the os calcis. You notice that he walks fairly well, and upon removing his shoe you see that he has a fair range of flexion of the foot. The shoe he finds most satisfactory is one in which the inner portion over the heel is supplied with a triangular pad, to take the place of the prominence normally presented by the posterior portion of the os calcis.

CURRENT LITERATURE REVIEWED.

IN CHARGE OF ELLISON J. MORRIS, M.D., AND SAMUEL M. WILSON, M.D.

JOURNAL OF CUTANEOUS AND GENITO-URINARY DISEASES

For January. Drs. Bernard E. Vaughn and Henry T. Brooks make a

Preliminary Report on the Study of the Gonococcus.

A condensed history of the study of this organism in its relation to gonorrhœa is given. The development is restricted and the virulence destroyed by the use of alkaline culture medium. The temperature best suited to the growth is 36° C. It will not grow below 25° C., nor above 40° C., and the cultures retain their vitality from four to six weeks if prevented from drying, while gonorrhœal pus has been kept moist and found virulent after seventy-one days. It is not very susceptible to chemical germicides. In some instances observers have inoculated patients about to die with pure cultures and in the recorded cases this attempt was unsuccessful when high fever was present—otherwise gonorrhœal urethritis developed.

In Finger's report of the only recorded autopsy on a case of acute gonorrhœa (produced in this way) the flat epithelium of the fossa navicularis was covered by pus corpuscles and these were also in the interstices between the cells, but the cells themselves were practically undisturbed. Elsewhere the cylindrical epithelium was displaced and the deeper transitional cells were infiltrated by pus cells. Wherever a follicle caused a break in the epithelium the inflammation was more intense and extended deeper, and the intensity of inflammation was directly proportional to the nearness to a follicle. The sinuses of Morgagni and the ducts of Littre's glands were found plugged by masses of pus corpuscles. The gonococci were found on the surface only of the squamous epithelium but penetrated pus corpuscles and also the cylindrical epithelial cells and the connective tissue.

All cases applying for treatment for urethritis were microscopically examined as follows: Pus was collected on a glass slide directly from the meatus; a second slide was drawn over the first to uniformly distribute the matter, and both were dried.

The following solution: concentrated alcoholic solution of methylene blue, 30 c.c., solution of potassium hydrate, 1-1000,100 c.c., was now applied by a pipette and then washed off in water, and the specimen dried over a flame. Examination was made with a one-twelfth oil immersion lens without cover glass.

The appearance coincides with the description of Finger: a diplococcus each half of which resembles a coffee bean, having a straight and curved border, the two halves lying so that the straight edges almost coincide, a small slit only intervening. These differ from other diplocci in being found in groups, never in chains, the number of individuals in each group being divisable usually by four.

JOURNAL OF NERVOUS AND MENTAL DISEASE.

for February. Dr. Morton Prince discusses

Traumatism as a Cause of Locomotor Ataxia.

A number of instances are given in which traumatism, more or less severe, appeared to be the cause of locomotor ataxia; but in none of which it could be proven the cause after a careful review of the history of the patient.

In order to recognize traumatism as the cause in a given case it is necessary to show:

First. That the patient immediately before or immediately after the injury was free from locomotor ataxia.

Second. The subject must be shown to have never had syphilis or been exposed to other well-known causes. One authority claims that ninety per cent. of all cases are due to syphilis.

Third. The traumatism must have produced a physical or psychical impression of greater extent than individuals frequently suffer without pronounced ill effects.

Fourth. The symptoms must have appeared within a reasonable time after the receipt of the injury. The author limits this time to one year.

Fifth. There must be no reasonable doubt as to the diagnosis.

Reviewing such published cases as he had access to the reports of the author was able to find only three or four which were not open to serious objection under one head or another of the table just quoted. Even in these few the absolute proof of absence of disease of the spinal cord immediately before or immediately after the accident is wanting.

It is well known that in cases of unmistakable syphilitic disease of the nervous system it is frequently impossible to get any history of such infection, and the author is disposed to think that at best traumatism simply draws the attention to a disease which may have existed, unrecognized, for some time previously, or perhaps even causes an exacerbation in such cases.

ALIENIST AND NEUROLOGIST.

Dr. James G. Kiernan writes of the

Evidence of Sanity in Criminal Cases.

A number of points for consideration are presented, some of which have been lost sight of, or else denied by experts in criminal cases, the result being a decision not in accord with the opinion of the author. Five propositions are given as follows:

First. Criminal acts committed by the insane often originate in logical motives.

Second. Acts committed by the insane for insane reasons are often referred to logical motives.

Third Acts committed by the insane may be the distant outcome of an insane delusion, yet the act be the result of a logical, seemingly sane motive.

Fourth. The execution of decidedly insane projects may be interfered with by a healthy conception.

Fifth. An insane man committing homicide for insane reasons may take due precautions to preserve his life for the execution of delusional projects.

Very interesting cases are cited showing clearly the full meaning of each of these propositions, and also how exceedingly apt a jury would be to judge an insane man sane if he acted in certain ways, which, on the contrary, would decide an expert's opinion in the opposite direction.

The same journal quotes from the *Gazz. degli Osped* the report of the cure of two cases of progressive paralysis by causing subcutaneous abscesses along the spine by means of irritating hypodermics. Mention was made at the same time of the cure of a case after an attack of typhoid fever, and of two cases by attacks of small-pox. One of the attacks of this latter disease had been intentionally produced.

From the *College and Clinical Record* Dr. T. J. Mays is quoted as stating that strychnine in increasing doses (1-32 grain gradually raised to ¼ grain, or more, four times daily) exerts a favorable influence on all of the symptoms of pulmonary phthisis. This is regarded as further evidence that this disease is due in great part to faulty pulmonary innervation.

PERISCOPE.

IN CHARGE OF WM. E. PARKE, A.M., M.D.

MEDICINE.

The Importance of Early Diagnosis of Chronic Kidney Disease.

(Benjamin Wilson, N. Y. State Med. Rep.) Albuminuria has ceased to be considered decisive as to renal lesions, and, when the only evidence, is not to be accepted as conclusive. It may be present when serious lesions are absent, or absent when continned lesions are manifest.

Every disease of the kidneys does not give rise to albuminuria, but the persistence of albumin in urine is indicative of a pathological condition in some part of the body.

Urinary casts are ranked among the surest signs of kidney disease. They are always to be regarded with the greatest suspicion, yet they may occur under numerous conditions, where the causes may only be temporary. The hyaline or mucous cast, while ever significant as the exudation cast described as the waxy or amyloid. The former is suggestive of nephritis in some stage, while the latter is proof positive of chronic degeneration.

Anuria and polyuria are important guides when they can be dissevered from a mental or bodily condition of a temporary nature capable of producing either.

To summarize:

Albumin is inconstant and bears no relation to the extent of the lesion, but when present should be respected as a prominent factor in diagnosis, making its appearance after other well-marked syptoms have existed; the disease is grave when albumin is present in pathological quantities and associated with casts.

Neither the absolute total quantity of the urine passed daily, or its percentage amount gives us much help in the diagnosis of renal disease. But toward prognosis there is no information more valuable than that of a prolonged series of urea analyses, to anticipate a dangerous accumulation in the system.

The literature of Bright's disease in its protean form is voluminous, and yet the knowledge of the subject is very imperfect, confused and unsatisfactory. The pathological anatomy of inflammation of the kidneys is the most extensively studied, but at the same time the least finished chapter in medical science.

How Long is Syphilis Contagious?

In a paper upon this question, published in the *Jour. Am. Med. Asso* , Dr. J. D. Thomas maintains that "Syphilis, being purely an inoculable disease, when the zymotic period has exhausted itself the patient is no longer capable of conveying or transmitting the disease.

"All zymotic diseases have a pretty uniform history of invasion, period of acme and period of decline. Syphilis is not an exception to this rule. Let us take, for instance, diphtheria. Six months after the disappearance of the active stage the patient may be suffering with paralysis. The paralysis is not diphtheria; the condition is not a contagious one; it is a sequel. No one has the temerity to assert that a person who has had scarlatina or small-pox continues to carry about, for months, in his system, the germs of these diseases, although the one disease may cause, for an unlimited time, a suppurative otitis and the other a necrosed maxilla.

Why should not the same reasoning hold good with regard to syphilis? Why should such a large number of the profession still hold to the idea that the sequelar lesions of syphilis are contagious? But recently I heard a gentleman make a statement to a medical society that he had treated a patient for syphilis ten years before the patient's marriage, and that after the marriage the patient infected his young wife. To me the statement was absurd. I did not deny the contagion, but did the source. The belief by some that the contagious character of syphilis persists for decades is an error due to faulty observation or to a lack of observation. Without entering any further into polemics, I make the assertion, in language more forcible than elegant, that patients may be rotten with the sequelar lesions of syphilis and at the same time indulge in intercourse and procreate off spring, without conveying the disease to the one or transmitting it to the other."

In corroboration of this opinion, five carefully observed cases from the author's notebook were presented—two bearing upon the hereditary feature of syphilis, and two others which proved the clinical fact that they were infected, not by the husband, but by fresher syphilitics. The conclusion arrived at was, "that syphilis can only be conveyed during the primary and secondary stages, and that the secondary stage ends not later than the third or fourth year from date of infection. . . . The chaotic views held by many of the profession in regard to the contagious period of syphilis are due to the acceptance upon their part of the word of the patient. We should not, and can not afford to base scientific axioms upon statements made by members of the laity. These statements are often studied deceptions; at other times they are honestly given, but from different premises."

Pain and Sleep.

It is certain that pain is one of the best antidotes to sleep. It may vary in intensity from a grumbling toothache to the sharp darting pains of neuralgia. It often follows that even after the pain is relieved the nervous system of the patient has received such a shock that sleep is impossible. Opium will quiet the pain but in many persons it has the affect to produce a condition of extreme wakefulness. Then again in persons who have been working for a long time under great mental pressure, we have a sleepless condition which contra-indicates the employment of any form of opium. In this condition the overworked nervous system is very likely to manifest itself in aches and pains of a neuralgic character. Therefore we find brain workers subject to a most annoying and obstinate insomnia. For all of these conditions we know of no better combination than the tablet composed of phenacetine and sulfonal. The phenacetine will control the pain whether it be of the severest character or only some slight neuralgic twinge; while the sulfonal is a hypnotic of a positive and fixed value. So far as we know attention has not been called heretofore to this particular combination. The therapeutics of each of the drugs mentioned will at once indicate a number of conditions where it can be used to the best advantage.

Diagnostic Importance of Enlargement of the Cutaneous Veins at the Lowermost part of the Thorax.

Dr. W. Hirschloff calls attention to the high diagnostic value of these venous dilatations. Affections of the lungs, heart, serous membranes surrounding these organs, mediastinal diseases and those of the great vessels will give rise to such signs. They are in general due to two causes—hindrance to the venous return to the heart and development of collateral circulation. As the veins of the anterior thorax empty into the superior vena cava through the internal mammary, the intercostal veins and the brachio cephalic trunks, a compression of these vessels would cause a consequent enlargement of the cutaneous veins Compression is generally caused by primary or metastatic new growths of the mediastinal space; lymphomata, lymphosarcomata, substernal strumous growths, or pulmonary neoplasms, aortic aneurisms or enlarged bronchial glands. Often the dilated veins are the first signs of intra-thoracic disease. Another very frequent cause of extensive venous nets forming on the thorax is a preceding contraction of the pleura or pericardium after preceding inflammation of these membranes, frequently occurring years before. This may cause nearly complete obliteration of the greater vessels and even death. Venous dilatations developing in the course of a few hours are dependent upon thrombosis of either the jugular, subclavicular or anonymous veins. As this more frequently is observed on the left side, the corresponding enlargment will be observed on this side. Dilatations from mere mechanical pressure sometimes give rise to very extensive enlargement, even of the size of one's finger, as in a case observed by the writer, where from capillary dilatation the arterial pulse was transmitted into these veins so as to cause them to resemble arteries. Yet on deep expiration, this pulsation would cease and the vessels be overfilled. In some cases thrombosis of these veins has been noticed. There is still another form of dilated veins, at the lower portions of the thorax especially. The vessels are prettily arranged in a branched and dendritic manner along the border of the lowest rib. They are dependent upon defective muscular action in this portion of the chest in respiration; they are liable to be quiet pronounced in four-fifths of emphysematic patients.—*Deutsche Medizinische Wochenschrift*, New York *Medical Times*.

Hemorrhage in Pregnancy.

Cases are by no means rare where slight hemorrhage, or something resembling menstrual flux, occurs at the time for the regular catamenial period for the first two months of

pregnancy, and in some cases extends during the entire period. This condition does not necessarily indicate placenta prævia, for where that exists Playfair says the hemorrhage rarely begins before the end of the sixth month, and sometimes not till labor has commenced. Depaul, in 70 cases, says in 1 case only the hemorrhage occurred before the sixth month; in 7 from six to seven months; in 12 from seven to eight months; in 26 from eight to nine months; and in 24 at term or near. A month before actual labor it is not unusual for slight pains, resembling labor pains, to occur at regular intervals, even with the slight appearance of blood. Of course in these cases the strictest rest should be enjoined and, if necessary some remedy used to check the pain.—*N. Y. Med. Times.*

Inflammation of the Middle Ear of Infants.

Dr. A. Hartman (*Deutsche med. Wochenschrift*) gives the results of investigations of this subject in the Institute of Infectious Diseases, Berlin:

1. Post-mortem examinations and examinations of the ears of living children establish the fact that 75 per cent. suffer from inflammation of the middle ear.

2. Inflammation of the middle ear can nearly always be determined by an otoscopic examination.

3. The symptoms of the otitis media consists of restlessness, elevation of temperature and loss of weight. Sometimes these symptoms are not present.

4. Very often the symptoms of otitis media are connected with broncho-pneumonic processes. Probably both processes are due to the same process, viz., aspiration.

5. Death can result in cases of otitis media, slow stone atrophy, or from an extension of the micro-organism into the cranial cavity (meningitis), or into the blood (septicemia).

6. The inflammation of the middle ears of infants must receive treatment suitable for the varying conditions.

Abortive Treatment of Gonorrhœa by Permanganate of Potash.

Large injections of permanganate of potash methodically used is the best method of treatment yet introduced. Its advantages are, being absolutely painless in cases of anterior urethritis, and scarcely painful in cases of inflammation of the whole tract; it can be commenced or left off without inconvenience; it has no detrimental action on the mucous membrane, but suppresses every trace of discharge from the first lavage, and is successful about eleven times out of fifteen. The size of the injection, and its frequency and strength, must be adapted to individual cases. Generally, strengths of 1 to 4,000, or 1 to 2,000, or even 1 to 1,000, are tolerated.—*Times and Register.*

Relation of Gastro-Intestinal Affections of Female Genital Organs.

Theilhaber (*Munch. Med. Woch.*—*Boston Medical and Surgical Journal*) gives details of forty-five patients who had been sent to him for gynecological examination by Dr. Cramer, a specialist for diseases of the stomach and intestines. They all suffered from stomach disorders, twenty-five with nervous dyspepsia, twelve with atony of the stomach, two with catarrh of the stomach, two with chronic intestinal catarrh, and four with other affections.

The gynecological examination revealed absence of any abnormality in four cases; in nineteen, catharrhal endometritis, with more less thickening of the parenchyma of the uterus; in four, endometritis hemorrhagica; ten cases of retroflexion and version of the uterus; three of oophoritis; two of parametritis; one of old puerperal parametritis; one of retroversion of the anteflexed uterus; and one of small ovarian tumor.

As regards the connection between the gynecological troubles and the stomach and bowel affections, Theilhaber divides the cases into three groups. The first embraces those cases in which the gynecological condition is only a chance occurrence. In the second group belong those cases in which the gynecological disturbances are caused by the gastro-intestinal affection; Theilhaber mentions here especially cases in which metrorrhagia and dysmenorrhœa are caused by constipation. In the third group the uterine condition is the cause of the stomach trouble.

Six of the patients with nervous dyspepsia suffered from retroflexion; in four of these the dyspepsia was cured by the reposition of the uterus; in two, not. Nervous dyspepsia and endometritis hemorrhagica existed in three cases, In two the digestive difficulties, which had existed for years, disappeared after curetting; one patient withdrew herself from treatment.

Of eleven cases of nervous dyspepsia and catarrhal endometritis, local treatment of the uterus had prompt effect in eight. Four cases of atony of the stomach which were associated with various local conditions were cured coincidently with the cure of the uterine conditions. Theilhaber concludes from his observations that in all cases of nervous dyspepsia, atony of the bowels or of the stomach, hyperacidity, want of acidity, and periodical gastralgia, in women where for a long time a rational medicinal treatment has not been successful, a thorough gynecological examination should be made, especially when the patients complain of menstrual irregularities or of leucorrhœa. Still, though the gynecological treatment is important, it is often necessary that treatment of the stomach trouble should be also carried out.

The Value of Diphtheraia Antitoxin.

The discussion on the value of the diphtheria at the Berlin Medical Society, was concluded at the third session of the society. Dr. Schiemmann warned general practitioners against employing the antitoxin, which he said should be left to the hospitals for the present. Professor O. Liebreich, director of the Pharmacological Institute of the University, criticised the published serum statis-

tics. He said that the Berlin hospitals had always had a much higher percentage of deaths from diphtheria than the Berlin town practice. This was because, broadly speaking, only serious cases were brought to the hospitals. But since the introduction of the serum treatment a far greater number of cases—and cases of all sorts—had been brought to the hospitals, and so it was quite natural that the percentage of deaths had fallen considerably. He considered the serum treatment to be based on fallacies very similar to those which had formed the foundation of the tuberculin treatment. It would be interesting to find out, he added, what action on the organism injection of pure indifferent serum would have. Dr. Hansemann, in a few last words, stood to his view that antitoxin is not to be regarded as a specific for diphtheria.

SURGERY.

Concerning Aristol in Surgery.

"Iodoform is that toxic compound of iodine and sulphur, which, though employed as an antiseptic may any time poison our patients; and anyone who knows anything about bacteriology is aware that it possesses no antiseptic power, whatever, though all must admit that in tuberculous or syphilitic sores it exerts a most marvelous stimulating power in the process of repair.

"After iodoform comes aristol, a drug which is more efficacious than the former and without its dangerous lethal properties. Under all circumstances it is to be preferred to iodoform when a deodorizer and antiseptic is called for.

"Aristol is devoid of any offensive odors of iodoform, and in light applications over wounded surfaces, forms an impervious scab or shield under which healing rapidly advances. It certainly is the most valuable dry powder we have in our possession at present for many lesions of the periphery.

"Aristol is of an immeuse value in the treatment of burns, having a remarkable influence for the relief of pain. It occupies a high place as a cicatrisant and antiseptic. It may be used dry, as an ointment, or combined with benzoinol.

"Aristol is of great value in malignant tumors, especially during the stage of ulceration, and may even be used internally for cancer of the stomach.

"In prescribing aristol in ointments a little ether should be rubbed with the drug before mixing with the base. This gives a much finer division than is usually found."
—Ed. *Times and Register.*

Treatment of Fracture of the Clavicle by Suture.

Routier (*Rev. d'Orthopedie*) is strongly in favor of suturing in certain cases of fracture of the leg, with the aim either of facilitating reduction which cannot be effected by ordinary means, or of maintaining reduction when it would be otherwise impossible or difficult to keep the fragments in good position. In cases of simple fracture of the clavicle, on the other hand, he would in general trust to bandaging, as a slight deformity, due to a moderate deposit of callus, would be less objectionable than the scar left after the application of the suture. The author would not hesitate, however, to treat fracture of the clavacle by an open operation in any case in which there might be a risk of much subsequent swelling and serious deformity; and, also, whenever it might be found impossible by ordinary means to overcome such displacement as would not only be unsightly, but also influence very seriously the innervation of the upper extremity. Exposure of the seat of fracture under such circumstances would enable the surgeon to place the broken surfaces in apposition, the application of a suture not being necessary unless it be found difficult to keep the fragments in place. A case is reported of fractured clavicle with extreme deformity due to over-riding of fragments in a female patient, aged twenty-two, which was successfuly treated by exposure of the seat of injury, removal of a detached fragment of bone, and suturing of the two main fragments of the broken clavicle. Three weeks after the operation there was perfect union. The linear cicatrix was small and hardly perceptible, the shoulders were symmetrical, and the patient seemed to be free from the least trace of deformity.

Resection of the Entire Left Lobe of the Liver.

Professor E. Tricomi reports the case of a man, aged 27, in which he extirpated the entire lobe of the liver for adenoma originating in the bile ducts. After resection of the ensiform appendix and division of the ligament. coronar. and triangular., as well as of the rectus, that portion of the viscus containing the tumor was drawn without the abdominal wound, which was sutured. The neoplasm was compressed by means of elastic tubing and metal loop, and necrosis brought about. On the eighteeth day, after application of a segmented suture above the ligature, the tumor was separated with the knife; cicatrization occurred on the ninety-sixth day.— *Wien. med. Presse.*

Resection of the Lower Jaw.

Moty presented two cases, in which he resected one-half of the lower jaw, to the Paris Society of Surgery.

M. Berger remarked, in discussing the cases, that, notwithstanding that it has been regarded as an inevitable consequence of this operation that the remaining part of the jaw becomes deviated toward the resected side, in these two cases this distortion did not exist. This demonstrated that the immediate application of appliances to prevent this occurrence is not indispensable.

SCORBUTUS IN INFANCY.

CLARA F. DERCUM, M.D., PHILADELPHIA, PA.

Cases of scurvy in infancy and childhood are of such rare occurrence that, hitherto, but comparatively few cases of this affection have been reported. However, it is well described by Thomas Barlow in Keating's *Cyclopædia of the Diseases of Children*. This author gives to Dr. Ingersloe the credit of having been the first among the continental physicians to recognize and report a case of this disease. (*Virchow's Jahresbiruht*, 1873, p. 697), and to Dr. W. B. Cheadle the credit of being the first English physician to show on clinical grounds the relations of this affection to the adult type of scorbutus. But to Dr. Barlow himself belongs the great credit of having shown the anatomical characteristics of the disease as determined by post-mortem examinations. Dr. Wm. B. Northrup (*Archives of Pædiatrics*, Jan. 1892), reported two cases which came under his own personal observation, and also reported fully several other cases which he had collected.

The pathology of this affection is still one of the unsolved mysteries of medicine. However, one thing has been definitely proven beyond a doubt, and that is that the primary cause of the changes which occur is improper feeding.

As yet microscopical examinations have revealed nothing, but it must be inferred that the blood vessels undergo some change, in order to allow the blood to extravasate through their walls. Up to the present time, no culture experiments have been made in order to determine the presence or absence of a special bacterium.

The anatomical lesions reported by Dr. Barlow have been corroborated by Drs. Northrup, Stephen, Mackenzie and several others; the lesions are as follows:—Blood extravasations between the actively growing periosteum and the subjacent bone, which is considered the primary scorbutic bone change. These extravasations are best seen in the legs and thighs. There may be a more or less complete sheath of blood clot between the separated periosteum and the shaft of the bone; the bone may undergo atrophy from pressure to the extent of fracturing at the slightest violence, when this unfortunate accident occurs it is generally above the juncture of the shaft with the epiphysis, but it may also take place in the middle of the shaft. These anatomical changes occur more frequently in the bones of the lower extremities than in the upper, but no bone in the body is exempt, for the ribs, the scapulæ and the bones of the skull may be involved; the eye has been known to bulge forward (proptosis) from extravasation between the periosteum and the orbital plate of the skull. Hemorrhages may also be found in many of the internal organs.

The distress and suffering in this infan-

tile form of scurvy is easy of explanation when we view the hemorrhagic extravasations between the bone and the periosteum. In the adult the effusion of blood generally takes place into the muscles and cellular tissue, giving rise to the well-known brawny indurations, and is therefore attended with far less suffering.

The symptoms in the beginning of this disease, are usually not well marked. Perhaps the only thing noticed at first, is the fretful cry on being picked up. Very soon the attendants will notice that the legs, if the trouble be in the lower limbs, will be held perfectly immobile. This condition may go on to pseudo-paralysis. If the disease be not checked, the tenderness and pain on handling become excessive; the skin appears shining and tense without any local rise in temperature. When the swelling goes down the prominent thickening of the shaft. will be noticed upon palpation. In rare cases this bone affection will be more marked in the upper than in the lower extremities, especially at the lower end of the radius. When teeth are present there will usually be swelling and bleeding of the surrounding gum, which may be so swollen as to protrude from the mouth. However when the teeth have not yet been cut this condition will be absent. On the surface of the body there may be ecchymotic spots, varying in size from pin points to quite large bruises; or there may be a roscola present. These spots are also occasionally seen on the mucous membranes. Hæmaturia, hæmoglobinuria, bleeding from mucous membranes and profuse sweating of the head are all conditions which may be present.

The treatment in such cases must be strictly hygienic; plenty of fresh air; fixation of the affected limbs; wet compresses will often relieve the pain. The diet must be strictly regulated. Raw milk but slightly diluted, raw beef juice, orange juice, lemonade, mashed potatoes, boiled cabbage and stewed tomatoes. Medicines are of far less importance; ergot and the dilute acids being the only drugs that possess any value. Under this treatment the most hopeless cases will often show signs of improvement.

The differential diagnosis of this affection will not be difficult to those who have once seen a case, or even to those who bear in mind that such a disease does exist. Where mistaken diagnoses have been made, it has been ascertained that the disease had been mistaken for either rheumatism or inherited syphilis; and these are probably the only two affections with which it could possibly be confounded.

The case which came under my observation is that of a baby, born in this country of an American mother and a Scotch father. The father is a very strong, robust man, but the mother is rather a delicate, fragile woman, who passed through several severe illnesses before the birth of the child. The mother's history is as follows: In August, 1891, she was seized with an attack of typhoid fever, which lasted two months. In November of the same year, just as she was considering herself comparatively well, she was taken sick with la grippe, which lasted fully six weeks. It assumed the gastro-intestinal form and she really seemed to be passing through another attack of typhoid fever, only that her temperature did not seem quite so high. During her convalescence, she suffered from acute melancholia. However, complete change of scene and surroundings restored her to her normal mental condition, although her health was still far below its usual standard. Upon her return home in February, 1892, she conceived, and in November of the same year she gave birth to a male child, which was much below the usual size of her babies. In April, 1893, the mother had another acute attack of melancholia. It was then deemed advisable to wean the baby and to send her away again.

The child was put upon Fairchild's peptogenic milk powder, and great care was exercised in the use of the bottles and milk. However, as the hot weather came on, the baby developed a chronic gastro-enteritis which lasted the whole summer. Some days the child did not get anything but egg-water, barley water and a little mutton broth. The milk was digested for half an hour generally, and was given whenever the stomach could tolerate it. Several weeks spent at Atlantic City effected no change in its condition. It was only as the summer began to wane that its state began to improve. On October 15, 1893, at the request of the father, he was vaccinated, and this was done upon the left leg. On the 27th of the same month I was sent for and found

him covered with a roseola which I paid no farther attention to, attributing it to the vaccination. A few days later, while I was attending one of the other children, the mother told me the baby was so cross and fretful he would cry on being picked up, and that he couldn't bear to have his legs touched. The vaccination scabs were examined and it was noticed that they were surrounded by a dark purple areola. However, the pain was still attributed to the vaccination and the mother told not to worry; that he would probably be all right in a little while. On November 10, the mother became alarmed and I was again sent for. She told me it had been impossible to bathe him for several days, as handling seemed to cause him to scream, and even when he was not touched he kept moaning constantly. I found the following condition: rose-red punctate spots scattered over the trunk, the vaccination scabs were nearly off and blood was oozing where separation had commenced, they were still surrounded by a large purple area; the upper and lower incisors, which were the only teeth through, were surrounded by slightly swollen purple gums, and, the roof of the mouth was filled with bluish spots. The napkins were stained a dark brown by the urine, showing the presence of hemoglobinuria. A hard laryngeal cough which was present was attributed to slight hemorrhages into the mucous membrane of the larynx. The rectal temperature was 106° F. In no recorded case has the temperature been noted so high. It generally ranges from 100° to 102° if present at all. The legs were held in a perfectly immobile position; the lower end of the femoræ and the upper part of the tibiæ were found very much thickened. He screamed when the arms were grasped. The characteristic beading of the ribs was present, as was also profuse headsweating.

The condition being now fully recognized, he was put upon the appropriate treatment, although some misgivings were entertained as to the final result on account of the high temperature and the extreme suffering which was present. The treatment consisted in cold sponging; wet compresses around the legs and thighs; the administration of dilute sulphuric acid and ergot in drop doses. The peptogenic milk powder was stopped and in its stead plain raw milk, raw beef juice, lemon and orange juice were given. During convalescence cabbage, potatoes and tomatoes were given.

After a few days the temperature gradually fell to normal and the symptoms began to ameliorate, so that in about one week after treatment had been instituted he could again be comfortably handled, although it took several weeks for the shafts of the bones to become normal.

After the vaccination scabs came off, slight oozing continued from the raw surfaces for several days. What relation vaccination had, if any, to the scorbutic condition it would be impossible from our present knowledge to state, although some cases of purpura following vaccination have been reported.

In England, where there are more proprietary baby foods sold than in any other country, the disease is not so rare.

In Germany some of the most eminent physicians have never seen a case.

This baby had been on milk and water, equal parts, to which cream and the peptogenic milk powder had been added. The milk was sterlized and perhaps the child's condition may have been due to this. He has developed into quite a sturdy little lad, although last summer he had another prolonged attack of gastro enteritis.

Bleeding at the Nose.

Dr. Kohn (*Northwestern Lanset*, condensed from *Medical Record*) suggests the following as a scientific and rational plan of dealing with all cases of nosebleed:—The patient is to sit quietly with the head thrown slightly back. All tight clothing about the neck or chest is to be loosened. Breathing through the nose is to be entirely suspended as well as all attempts at clearing the nose or throat. The patient then is told to breathe rapidly through the mouth; say thirty times a minute until he is tired, sounding a broad "A" with each expiration so as to shut off the posterior nares from the throat by bringing the soft palate against the posterior wall of the pharynx. These manœuvres place the nose at rest by stopping the passage of air through it, diminish the flow of blood to the head by the rapid respiration which determines the flow of blood to the lungs, and shuts off the posterior nares. They are simple measures, and if not successful prepare the way for the next step of insufflation of tannin or astringents, followed if necessary by plugging the nostrils.

REMOVAL OF THE DISEASED OSSICLES IN NON-SUPPURATIVE OR CHRONIC MIDDLE-EAR INFLAMMATION.

LAURENCE TURNBULL,* PH.G., M.D., PHILADELPHIA.

The operation in non-suppurative or chronic middle-ear inflammation has received the term "Otosclerectomy" from the Greek for ear and hardness or excision, or from the surgical removal of sclerosed and anchylosed conductors to sound. Now and then we meet with cases of failures in the hands of our best surgeons, even in carefully diagnosed and selected operations, to relieve deafness, vertigo, etc. "To err is human," and in our experience of many years practice of the profession, we have witnessed some errors and have received authentic reports of sad results from others; and not only do these occur in the hands of the tyro, but in those of professors and hospital surgeons of our cities.

In properly selected cases of non-suppurative or chronic middle-ear inflammation our success has been good. When we find a patient with an obstruction anywhere between the thickening and adhesions of the membrana tympani, anchylosis of the malleus, of the incus, but not the same condition of the stapes, we consider it safe to operate. It is almost always necessary to perform a preliminary operation by opening up the drum membrane or resecting the malleus or incus, removing a section of the diseased bone and diseased tissue. When we find this preliminary operation improves the hearing, or relieves the tinnitus and vertigo, it is not always necessary to complete the operation if the hearing is satisfactory.

In some rare cases this operation will sometimes check even progressive sclerosis, by making a long incision in the membrana tympani posterior to the malleus, and to use traction on the incudo-stapedial joint. If these are not effectual in removing the annoying symptoms then it will be safe to resort to the full operation, *i.e.*, excision of the membrana tympani and ossicles. In our hands cases with a dreadful feeling of pressure, which were seen at the aural clinic of the Jefferson Medical College, have experienced much relief of a permanent character by opening the drum and removing the malleus. On examination there has been found diseased bony structure without giving any other indication on its surface; we have found similar disease in the mastoid region, where in two cases an opening was found in the bone large enough to admit the tip of the forefinger. We never, as yet, have known of a death from the operation of removal of the diseased ossicles; never have heard of a chronic discharge following an operation, or of mastoid or other complications, but cases have been reported where the hearing power and tinnitus have been made worse.

A case of death was reported in the *Medical Bulletin* for November, 1894, p. 448. Desiring further information on the subject I addressed a letter to the gentleman who reported the case and the following is his reply:

"My patient's statement, as near as I can remember, was that her friend's hearing had been improved by the operations (three, I think) performed. It became necessary, however, after the lady had gone to Washington, D. C., on her way to her home in the South, to have an opening made behind the ear, by a physician of that city whose name I could not ascertain. This latter operation it was stated was soon followed by death, the patient having in the meantime become nearly blind.

"My informer was of course unable to say as to the exact nature of the operations done in Philadelphia, and although I knew the operator fairly well, I did not feel at liberty to ask him under the circumstances any questions as regards the matter. He is a man who, although he is not connected at the present time with

* Aural Surgeon to the Jefferson Medical College Hospital; President of the Sub-Section of Otology of the British Medical Association, and the Section of Otology of the American Medical Association; Emeritus Physician to the Howard Hospital; Member of the Committee of the International Congress of Otology.

any medical colleges, has had considerable experience in intra-tympanic surgery. I am under the impression that the case was similar to one reported by Dr. Randall, in which mastoid disease requiring operative interference, was followed by intratympanic operation, which was probably due to displacement of the incus backward into the aditus or antrum, in the effort to remove it.

"I am sorry that I am not able to obtain more definite information as regards this interesting case. My patient could not tell me whether her friend had had any discharge from her ear previous to going to Washington, and she left Philadelphia apparently in good health."

The death was probably due to the tympanic operation as the primary cause. The fact that she left Philadelphia in apparent good health indicates that something quite unusual must have occurred, and it is quite possible that the operation was performed in a suppurative case with the hope of relieving an existing mastoid irritation or empyema, which, however failed in its object, and the more formidable operation therefore became necessary. Should this view prove to be correct then the surgeon was perfectly justifiable in the course he pursued and I should regard his conservative action as highly commendable.

Cases accompanied with atrophy or paralysis of the auditory nerve should not be operated upon. Again great care should be taken not to injure the Fallopian canal with the incus hook.

Children can be operated upon, and even old men have had great relief from the tinnitus and vertigo. As a matter of course the older the individual the less chance of restoration to good hearing.

We are all liable to accidents in so limited a space as we have to operate, yet much can be done to prevent them by great care in our manipulations. The use of antisepsis, a good electric light, and a proper clip for a lens on the back of the forehead mirror, is necessary for presbyopes.

The following are the indications where it is of benefit to use the operation upon the drum head and ossicles in otitis media chronica:

1. Deafness.—This has been improved but not in all cases. This is the writer's experience in cases of which he has positive knowledge.

2. Tinnitus and vertigo.—In this a larger number are relieved. The vertigo is not relieved in all cases by the operation, especially if there has been a true disease of the nerve, but it may be if there be only Meniere's symptoms with no change of the semi-circular canals, cochlea or brain.

After a few days careful preparation we employ cocaine or ether as the anesthetic. We illuminate the ear by the electric headlight. My method of operation has been modified after that of Dr. Sexton of New York, the pioneer in this operation in the United States, and we give his method first.

The technique of the operation in cases where the membrana tympani is not perforated. First make an incision behind the short process of the malleus, continuing it by means of a probe-pointed knife if the perforation is not large enough to permit withdrawal of the malleus. While the incus is held in position by its attachment to the malleus in front and by a short process behind, the long process may be seized by the forceps, and the entire bonelet withdrawn. With a curved two-edged tenotome, then, sever the tendon of the tensor tympani muscle by cutting upwards behind the short process of the malleus. With a probe-pointed knife or a curved sharp incisor sweep about the entire periphery, seize the malleus at or about the short process and withdraw the malleus and membrana tympani attached to it. Hemorrhage is gently mopped with baked or iodoform five per cent. cotton, and the meatus stopped with the same for twenty-four hours. The patient should remain in bed and in the house or hospital for five days. Use the iodoform cotton for stopping the ear. All sudden movements of the head or anything having a tendency to produce congestion should be avoided. If suppuration or mucous discharge occur use iodoform cotton. If the membrana tympani reform it must be torn down.

The indications for the operation are; first, rigidity from ankylosis in the ossicular canal; second, great impairment of the function of the drum (tympanum) as a result of catarrhal, acute or non-suppurative inflammation; third, where there is a very great relaxation of the transmitting

mechanism, giving rise to severe autophonic noises, vertigo, etc. The drum head is detached in the upper part by an incision so as to uncover the incudostapedial articulation. This is usually accompanied by a loud and distinct "click," and leaves the detached end of the incus—sometimes the incus is not seen and it must not be groped after—a bent probe is generally passed over its surface and some of its envelope detached. It is then brought down with the forceps, tight traction being made. The remaining attachment of the drum head should then be separated with the knife and together with the malleus removed.

THE MOBILIZATION AND EXTRACTION OF THE STAPES.

This operation was first proposed by Ricardo Botey (Berlin Congress, 1890), and modified and performed by Miot and Boucheron. An incision was made on the outer periphery and the stapes was extracted by a Palet hook. Kessel and Botey employed extraction through the fenestra ovalis in anchylosed and fixed stapes. Still later, L. Jack reported sixteen cases; five for chronic middle-ear catarrh and eleven for suppurative catarrh, in which there was a remarkable improvement in a number of cases. Then we have the synechotomy or section of the stapes suggested by Schwartze.

The most recent report on the removal of the stapes is by Clarence J. Blake, Boston, who states that he has found that the continuance of the cut, from the front just posterior to the short process of the malleus downward towards the posterior border of the manubrium, resulted in a turning of the flap outward in such a manner as to interfere with the accuracy of the alignment. The incision procedure was divided into two part—the first consisting in the opening already described, beginning at the round window 2 mm. in length, and following the periphery to the short process of the malleus; the second beginning posteriorly to and half way down the length of the manubrium and being carried upward to meet the termination of the first cut. He obtains most wonderful results from the use of a two per cent. solution of cocaine, applied on a cotton tipped probe, both in checking bleeding and pain. In this paper he reports four cases.

The first, a young woman of twenty-two years, with a chronic catarrhal inflammation of both middle ears. Prior to the operation, Politzer's acoumeter was heard at a distance of two inches, and the tuning fork (512 V.S.) aerially 10-65. The voice was heard only when spoken close to the ear. Two weeks after the operation the acoumeter was heard at a distance of twenty-six inches; the tuning fork aerially 15-65, by bone conduction 20-65; the voice in a moderate tone, heard at a distance of one foot, and the exploded consonants T, P, B, and D, were confounded.

The second case was a man of twenty-six years of age, in excellent general health, who had been deaf in his right ear since childhood, in consequence of suppurative inflammation of the middle ear which had resulted not only in the destruction of the membrana tympani, but with the loss of the two ossicles. Tests of the hearing—Neither the medium fork (512 V.S.) nor the large Politzer forks were heard at a distance of one inch from the ear; the larger fork giving only a jarring sensation, in the left ear the fork was heard. On the left, a Galton whistle was heard only in the lower numbering of the register. Two weeks after the operation there was no vertigo; the Galton whistle was heard throughout its whole scale, the tuning fork (512 V.S.) was heard aerially 26-65; the bone conduction on the mastoid at 40-65, but the hearing of the voice was not improved.

The third case was a man of fifty years of age, with progressive chronic catarrh. Before the operation the hearing, both for the acoumeter and the tuning fork (512 V.S.) was unappreciable. One week after the operation the hearing, both aerially and by bone conduction, was the same as before the operation.

The fourth case, Mrs. A. R., aged fifty-six years. In this case a two per cent. solution of cocaine was employed and yet there was pain. Hearing distance before the operation, by tuning fork 25-65 in the right, and 13-65 on the left. Eighteen days after, tuning fork 24-65, and the voice in a loud tone heard at a distance of three feet.

SURGICAL TREATMENT OF HEMORRHOIDS.

S. D. VAN METER, M.D., DENVER, COL.

It is my desire, in writing a paper on this subject, not only to summarize the evidence in proof that, in the majority of cases, the oldest surgical operation for this trouble—that of ligature—is the best, safest and surest, but to make an earnest attempt to explain why the quacks have such a hold on this branch of surgical science. I say oldest, for Hippocrates mentions its use, and, since his day, while the technique of operation is most likely improved, no better method for the cure of hemorrhoids has been discovered.

To-day no branch of surgery is more in the hands of charlatans than rectal diseases in general, and especially does the quack make capital of "painless cure of piles;" "without the use of knife or detention from business." When one knows that a case of hemorrhoids, in the hands of any competent surgeon, can be cured by a safe and simple operation, and is confronted with the fact that the ubiquitous pile doctors are reaping immense fortunes from the many sufferers from this disease, he most naturally ponders the question, "Why such should be."

Most things have a cause in this world, although 'tis often extremely difficult to reason back from effect to cause. In many instances where the explanation is hard and authorities differ, the cause is a combination of many minor causes. This I believe to be true in many instances.

First of all, so many general practitioners are apt to give their patients who consult them for rectal trouble (be it anything from cancer down to eczema) palliative treatment. Many cases they fail to examine, taking the diagnosis of the patient, which in most instances is "piles," missing thereby case after case demanding operation, which, if they had examined and diagnosed, could have had the proper attention. But, after using some anodyne or palliative remedy with, perhaps, temporary relief, one of these patients soon finds himself in as bad a shape as ever. Seeking relief, he steers his boat elsewhere; perhaps he falls into honest hands, but when a ship is afloat without a rudder no one will say to what point she will drift. When the fiendish "pile" doctors swarm in every harbor and are stationed on every out-post, flaunting in the face of all sufferers their enticing circulars written in every line with an appeal to the weak spots of human nature, is it surprising they should secure so many of these cases that are drifting in search of relief? No! And who is to blame? We cannot stop these charlatans in their diabolical work, but an appeal to men in general practice to be more careful with rectal cases, and thereby keep them out of the long grasping reach of the quacks, if heeded, should do good.

The natural timidity of the human race to undergo anything that suggests an operation drives many cases from the honest surgeon to the quack, who guarantees a cure "without knife or detention from business." It is hard to change human nature, but frank and plain explanation of what can and should be done by operation often dispels timidity and makes cowards brave. I have seen patients who are perfectly willing to have the ligature operation performed when told that no knife was to be used, all the cutting necessary being done with scissors, whereas, when they thought a knife would be required, they would not consent. Another factor that works in the interest of the pile doctor is the fact that many people are so very sensitive about having anything wrong with their rectum that they often prefer passing by their family physician and surgeons of personal acquaintance, to consult some obscure "orificialist," simply because by so doing they do not feel that hyper-sensitiveness. Yet, what do they sacrifice for such gratification!

There are other minor causes for the immense hold that charlatanism has on rectal surgery but those mentioned, viz., (1) the laxity of the profession in managing these cases, (2) the alluring schemes of the quacks, (3) the natural timidity of the human race to undergo any operation, and (4) hyper-sensitiveness of many individu-

als when affected with any rectal disease, are chief and those to be attacked by the profession if this branch of surgery, wherein so much good can be done, is to be wrested from the mire of charlatanry.

All of you know much of the ways and workings of the "rectal pocket cutters," "orificial surgeons" and "osteopathy" (the derivation and meaning of the latter, the Omniscient only knows), but unless you have by personal observation seen some of their diabolical work, you can but in a small degree imagine what these vampires are capable of doing. A case which came under my observation not long since is a fair example: One of Denver's most worthy gentlemen, suffering solely from over-work and mental strain, went East for recreation and change of scene. For further satisfaction he consulted one of New York's leading physicians who reassured him his case was a break-down from over-work with some dyspeptic trouble of slight importance, and that what he needed was rest and quiet. With this reassurance, he turned his course westward, intending to stop at quiet resorts taking the journey by easy stages, that thereby he could get the much needed rest of body and mind. At Chicago he was allured to that outwardly attractive institution, Pratt's Sanitarium. Here he entered with but one purpose, that of being retired from the noisy and busy world. Not the least thought did he have of submitting to an operation of any kind, and certainly not on his rectum, never having suffered the least trouble with that organ. This man, of strong mind and determination of purpose equalled by few, had not been in the "spider's parlor" forty-eight hours before the fiend who runs that institution had by his wily tongue and, you might say, hypnotic power, performed Whitehead's operation on his rectum, telling him, of course, of the pockets, little piles, etc., but that all he was going to do was to stretch his rectum. Yet, it was well known that this organ was practically normal. After this bloody operation, and especially in a patient of a generally weakened constitution, it is not surprising that retention of urine followed. Finding it impossible to pass a catheter without, the patient was anesthetized, and after an hour or more of endeavor, a catheter was finally forced into the bladder. Much hemorrhage followed as well as a violent cystitis, which came near ending in death. As soon as possible this gentleman left that infamous, misnamed sanitarium with its beautiful flowers, park, lake and drives, but not until he had paid $1,000 for the operation and $75 per week for room and board. Fortunately the operation healed by first intention. The cystitis yielded after persistent treatment, but, of course, his bladder condition of to-day is not what it was before the operation.

If this gentleman of exceptionally strong mind, full of business and determination, could be hoodwinked and robbed of health and money by one of these impostors, what must be the crime daily practiced upon those easily led, and, apparently willing to be duped? Preposterous! Beyond conception save by those who have seen it. 'Tis folly to reach these fiends through the law, and in a measure we are helpless, but repeated exposure of their deeds will be of great benefit.

They do not stop at telling the suffering invalid that an operation on his rectum will cure any disease there, but encompass all ailments that human flesh is heir to, claiming the fulgurant pains of tabes dorsalis and other similarly incurable symptoms will fade away like a snow bank before a summer's sun. One thing, however, that is most gratifying is that most of these men hail from the ranks of the followers of Hahnemann. Consequently, gentlemen, permit me to urge you who are not, to be careful how you manage your rectal cases. Don't be satisfied with palliative treatment when you find patients requiring operation. The majority of cases of diseases of rectum do not have to be sent to anyone making a specialty of such work. Select your cases of hemorrhoids suitable for operation; operate, and I am sure you will profit thereby and save many a poor sufferer from the misfortune of falling into the hands of quacks. If you do not care to operate on cases suitable, don't be contented with palliative treatment, but send them to someone who will perform the radical operation.

I am aware that there are men present who take issue with me and believe they can cure a great number of cases of hemorrhoids without resorting to operative procedure; but, gentlemen, while I admit there are a few cases which may be called hemorrhoids which can be relieved not to return by palliative treatment, I think

they are exceedingly rare, and I maintain that, *when hemorrhoids are well developed, nothing short of their removal will effect a permanent cure.* If the gentlemen will secure a full history to date of the cases they believe they have cured, and cancel from their list those who have gone elsewhere for treatment and those still affected, the remaining cases, I believe, will be exceedingly few.

Do not, however, understand me to advocate that every patient presenting himself for treatment who is afflicted with hemorrhoids should, immediately and forthwith, be operated upon. Far from it. But it is a fact worth remembering that the size of a hemorrhoid, in most cases, does not govern one in deciding whether or no an operation is to be performed. Surgical judgment alone can decide when an individual case requires operation. But, I do believe, when a suitable case presents itself, a doctor is doing that which is not right if he administers palliative treatment, when so simple, safe and sure an operation as that by ligature exists, and by which nearly every, if not all, cases of hemorrhoids can be permanently cured.

Passing over the dietetic, hygienic and palliative treatment when required, neither of which must be ignored in treating hemorrhoids, the question arises: What method recommends itself when we find a case requiring operation?

I believe there are twelve or thirteen recognized operations for the cure of hemorrhoids, all of which have the same purpose—that of removal of the tumors. Of these it is needless to mention but four—(1) injection, (2) Whitehead's operation, (3) clamp and cautery and (4) by ligature.

The injection method—the one chiefly used by the itinerant pile doctors—at one time bid fair to become popular, but its inefficiency, danger of death and other accidents, such as thrombus, ulceration and pyæmia, have justly brought down upon this method the condemnation of all men of standing and authority. The statistics gathered by Andrews are enough to make anyone look upon it as a bad operation and regard it as an unscientific and unsurgical procedure. Andrews' statistics show, out of 3,304 cases, deaths, 13; embolism of liver, 8; sudden and dangerous prostration, 1; abscess of liver, 1; dangerous hemorrhage, 10; permanent impotence, 1; stricture of rectum, 2; violent pain, 83; carbolic acid poisoning, 1; failure to cure, 19; severe inflammation, 10; sloughing and other accidents, 35. True, these statistics are from cases operated upon by unskilled men, but likewise are they from men prone to give the best reports possible, and, taking all things into consideration, one must, from these facts and the experience of men who have honestly tried this method, conclude that it is to be condemned as unworthy of a place among surgical operations.

Whitehead's operation—that chosen by the "orificial surgeons"—likewise cannot receive too strong condemnation. In brief, it consists of removal of the lower segment of the mucous membrane of the rectum, the so-called "pile-bearing area," and stitching together the cut edges of skin and mucous membrane by interrupted sutures. This bloody, dangerous and tedious operation can only be recommended in exceedingly rare and selected cases, and in these I prefer another. If union does not take place by first intention, the result is disastrous and the danger of septicæmia, unmanageable ulceration and consequent stricture is very great.

The operation by clamp and cautery, which just now is being revived, has some points to recommend it, but aside from cases where there is great relaxation with redundancy of tissue, I cannot see how it has any advantages over the operation by ligature, but it has objections not possessed by the ligation method, and I propose to consider them together. No operator, be he ever so skilled, can say when the cautery has completely sealed all blood vessels. The danger of secondary hemorrhage I believe to be greater than when the ligature is used. When the amount of pain a small burn causes is taken into consideration, no one can maintain that operation by cautery is painless. While with the true internal variety this question does not arise in the majority of pile operations, one is compelled to take in tissue supplied by the sensory nerves, and, when he does, most certainly the pain after cauterization is far greater than that after a clean cut. Then, the cautery method requires cumbersome or costly apparatus, which often gets out of fix when needed, and the mere suggestion of a hot iron is remindful of most unpleasant memories.

As the operation by ligature is simple, requiring but a few instruments; is safe, being almost void of danger; sure, because it successfully removes and cures the hemorrhoids, it is deserving of the commendation justly awarded it by the many eminent authorities on rectal surgery.

Allingham says: "I do not think in the whole range of surgery there is any procedure worthy the name of operation which can show a greater amount of success or smaller death rate than the ligature of internal hemorrhoids." Bushe, Bodenhamer, Ashton, Van Buren, Cooper, Brodie and Syme never lost a case. Gross, in such expressive language, said: "The operation by ligature is as simple of execution as it is free from danger and certain in its results."

Matthews, in summarizing the results in 1,000 cases, certainly gives strong evidence in favor of ligature. Not in a single case did he have to operate the second time. Such a consensus of opinion ought to be sufficient proof of the superiority of the ligature method over all other operations.

I have intentionally made no classification of the varieties of hemorrhoids, simply because I believe there is but one practical division, viz., internal and external, with a combination of the two. Further classification is useless, confusing and misleading: likewise is the elaborate technique of operation, given by many authorities, more than is necessary.

Preparation for two days prior to operation, by a saline the second, and a purgative pill the night previous, followed by warm enema the morning of operation, is the best preparatory treatment.

After anesthetization, the patient is placed in Sims or the lithotomy position, according to the preference of the operator. The parts are cleansed and irrigated with some antiseptic solution. I prefer 1-5000 bichloride of mercury. The sphincters then are slowly and gently dilated with one of the many bivalve speculums. After this, the two thumbs are placed in rectum, palmar surfaces outward, and the dilatation is completed until you feel a gentle relaxation, not a rupture of the sphincters. This generally brings all hemorrhoids into view, but, if not, by grasping one of those in sight, and with a little downward traction, all that are hidden will usually be easily seen.

With a stout ligature and vulsellum, the smaller tumors are picked up and firmly ligated. Larger ones are transfixed with double thread, tied above and below, and the major part cut off with straight scissors. If, however, as is true in most cases of large hemorrhoids, the lower covering of the tumor approaches or is composed of the skin, a sulcus, including any immediate redundancy of the integument, must be cut and the lower ligature tied therein. The dissection of this sulcus should be carried up sufficiently high that no branches of the sensory nerves will be included in the ligature, or else there will be much more pain. The white line of Hilton I believe to be a most unreliable landmark and often impossible to locate.

As to the external variety, it has been my experience that the best method to deal with them is to make a clean excision of each and every one. Any hemorrhage that may follow can be controlled, and if it is feared, after making the incision of the integument, a ligature may be the integument, a ligature may be used. The practice of removing a part of the larger piles, expecting the subsequent contraction to obliterate the stumps and the smaller tumors, I believe to be a mistake. A clean excision of all is the best. Small, insignificant tumors often take on inflammatory action and become worse than those removed, thus requiring a second operation. Acute inflammation of external piles in no way contraindicates operative procedure. Their removal is the quickest and best way to "reduce their inflammation," as many men think should be done prior to operative procedure.

After attending to all hemorrhoids according to this plan, dusting the parts with iodoform and returning the ligated tumors with a piece of gauze into the rectum, and placing a good compress of cotton over the anus, retained by a "T" bandage, the patient is ready for bed. Free use of morphine for the first few days, to control pain and prevent movement of bowels, is administered. Retention of urine must be expected in many cases, and must be cared for.

With a gentle purgative on the sixth to eighth day, aided by an enema, the ligated

tumors generally come away, leaving healthy ulcerating bases, which kindly heal. Cleansing the rectum with an occasional enema of cold water or weak mercuric solution, I think, hastens the convalescence. No matter how desirous a patient is of getting out, to guarantee success the prone position must be insisted upon until the healing is complete. In brief, a free and full removal by knife and ligature is the most satisfactory method of dealing with hemorrhoids. The fear of taking away so much mucous membrane as to cause consequent stricture is unfounded and has caused many failures to cure by the operator not taking away enough.

A better, safer, simpler and surer operation and one you can promise so much relief from, does not exist.

COMMUNICATIONS.

CEREBRAL PALSIES OF CHILDHOOD—REPORT OF SIX CASES.*

THEODORE DILLER, M.D., PITTSBURG.

Inasmuch as I have been unable to learn of any paper read before the society on the subject of cerebral palsies of childhood, I venture to present to you to-night the clinical records of seven cases, together with some observations on the disease.

The cerebral palsies of childhood are not very uncommon. They are, I fear, often unrecognized. The clinical features are, however, well known. On the subject of pathology (excepting of the birth palsies) very little is definitely known; and, as an almost inevitable consequence, numerous speculations and various conflicting theories abound. Among those who have critically studied this interesting subject, several of our countrymen deserve mention, especially Sachs, Osler, McNutt, Peterson, Dana, Knapp and Fisher, as having made careful and laborious studies. Of the foreign writers who have helped us to a better understanding of the subjects, Gaudard, Gowers, Henoch, Strumpell and Wallenberg deserve mention.

Complied from the writings of these authorities, I venture to submit the following brief outline of the affection, against which the cases I am about to relate may be measured. I have no autopsies, and so am unable to contribute anything to our knowledge of the morbid anatomy of the subject.

The very name, cerebral palsies, indicates our lack of knowledge as to the pathology and morbid anatomy. It signifies only that the palsy is one of childhood, and is cerebral in origin; and it is well, I think, that this name should be retained until we shall have gained a far better knowledge of the underlying pathological changes which produce these symptoms. The name polioencephalitis, suggested by Strumpell, and which carries with it the idea that these palsies are due to inflammation of the large motor cells in the cerebrum similar to that which takes place in poliomyelitis, has been very generally rejected as based upon too meagre and unsatisfactory evidence.

These palsies may be divided into those which are congenital, or occur just at birth, and those which occur in infancy and early childhood. The first named (often called birth palsies) occur usually in the form of diplegias and paraplegias; and are frequently, but not always, due to meningeal hemorrhages; while the latter occur in the form of hemiplegias, as a rule, and the morbid anatomy is variable, and indeed, enigmatical.

These two types may be most advantageously studied separately.

Diplegia or paraplegia results most frequently, as proven by the careful studies

* Read before the Allegheny County Medical Society, February 19, 1895.

of Sara McNutt,[1] from meningeal hemorrhages. In many of these cases the labor is prolonged, the pelvis contracted, the head large, or the instruments have been used. In short, parturition has been difficult. Congenital agenesis and parencephalus account for a few cases. Asphyxia (blue baby), with convulsions at birth, have been frequently noted.

This form of paralysis is an exception to the rule that paraplegia is usually of spinal origin. Until comparatively recently these cases were looked upon as spinal in origin. Why cases of birth palsies should be so very generally bilateral, has never been to me satisfactorily explained.

Aside from the convulsions which occur at the time of birth, no symptoms may be noted until the time arrives when the child should begin to creep or walk. Then it is noticed that there is loss of power in the legs, and perhaps in arms too. As months go by this paralysis becomes very apparent. The lack of mental development and power of speech too become noticeable. Convulsions frequently occur. Finally the child's condition is one in which there is a spastic paraplegia or diplegia, a mental condition approaching or akin to idiocy, and epileptic convulsions. Not rarely there are athetoid or choreiform movements or tremors.

Hemiplegia occurs, according to Dana[2] rather more frequently in males than in females; while according to Gowers[3], and Osler[4], the reverse is true. Most cases set in before the end of the second year. They are rare after the fifth year. In one-half of four hundred and twenty-eight cases collected by Osler[5] the disease began with convulsions, so that this symptom is a very important one. This convulsion is generally unilateral (Gowers). A number of cases set in during or upon the subsidence of an acute infectious fever, such as scarlet fever, whooping cough, pneumonia, measles, or mumps. There is frequently some febrile disturbance for several days at the onset. In a few cases the paralysis comes on gradually, without initial symptoms which attract attention. After the onset the paralysis generally improves (in a few cases almost or entirely disappears) in varying degrees, but the characteristic hemiplegic gait is usually present; stiffness with contraction of flexor and adductor muscles, appears—the so-called spastic symptoms. If hemiplegia be right-sided, aphasia may be noted. In time, more or less difference in the size of the limbs on the two sides becomes apparent, and in some cases grows to be extreme. This is not so much due to acutal atrophy, but rather to the trophic changes which leave the affected members in a more or less stationary condition; while the sound side, so to speak, grows away from it. With advancing growth, various forms of talipes are apt to appear, due to the over-action of certain groups of muscles.

Convulsions have a strong tendency to recur, and may do so with every degree of frequency (according to Sachs[6] about 45 per cent. of cases are epileptic); but, even when they do recur, there is usually a comparatively long period of exemption between the initial attack and the one which next appears, often of several months', and sometimes of three or four years' duration. Mental defects are usually observed after the acute onset, or when the child has become old enough for them to become manifest. Along with them, moral defect or perversion is often seen. The moral perversion may be much more apparent than the mental; indeed, may seem to exist in the absence of it, although I doubt if it really ever does. The mental deficiency is seen in all degrees, from extreme idiocy up to a condition of minor mental defect, which is scarcely appreciable. Rarely is mental deficiency entirely absent. In about one-fourth of the cases some posthemiplegic movement, either tremor, chorea, or athetosis is observed.

Morbid Anatomy. Autopsies which have been made, throw light only upon the secondary changes which occur. Sclerosis with atrophy and parencephalus (so called true and acquired), are the conditions found most frequently. In a few cases, embolism, thrombosis, and hemorrhage have been found. What is the primary change which causes such acute and violent symptoms as we see in the onset of this affection? This question

cannot be satisfactorily answered to-day. But it seems likely that the symptoms are produced by several causes; among others, hemorrhage, embolism, thrombosis and meningo-encephalitis. Gowers[1] believes that thrombosis of cerebral veins and sinuses is the cause of the trouble in a certain number of these cases, arguing that it is well known that thrombosis of veins does occur in children, and that sclerosis and parencephalus, secondary changes, may be explained on the supposition of such an antecedent condition. "It is a known consequence of such general diseases as frequently precede the cerebral lesion" (Gowers). The lack and need of definite knowledge of the morbid anatomy has been well emphasized by Osler.[2]

The diagnosis of birth palsies is not difficult. Paraplegia or diplegia with contractures, increase of reflexes, and the mental state described, starting from no definite period after birth, are enough data by which to recognize it. If there are convulsions and asphyxia at the time of birth, the diagnosis is rendered still more certain; and the lesion is, according to McNutt[3], Osler[4], Sachs[5] and Gowers[6], meningeal hemorrhage.

The hemiplegic form is likewise easily distinguished by sudden onset (often during or after fever), convulsions, spasm, contractures, increase of reflexes without immediate atrophy, or electrical changes; thus forming a contrast to the spinal palsies where there is absence of rigidity, and of exaggerated reflexes; and where atrophy occurs rapidly, and the electrical reactions of degeneration are found early.

Prognosis. Complete recovery is scarcely possible, although a certain number of these cases reach adult age and are able to earn a livelihood in useful occupations. The presence of mental and moral defects, together with epilepsy, render the prognosis very bad. From the paralysis alone there is often improvement, especially in the leg. Athetosis or other post-hemiplegic movements augur badly. They are exceedingly difficult to overcome, and will often persist even when paralysis improves. The prognosis in the diplegic and paraplegic is much worse than in the hemiplegic cases. Many of them get into institutions and die before reaching adult age. It should ever be borne in mind that convulsions in children may be the signal of an oncoming cerebral palsy; and this should lead us to watch all convulsions in children closely, and to be very guarded in our prognosis. It must certainly be a humiliation to say a convulsion is trifling, that it comes from "worms," or the "stomach," or "teething," and find a complete hemiplegia follow it.

Treatment must be symptomatic. Chloral, bromides, or chloroform, may be given if the child is seen in the convulsive stage. Afterwards earnest and systematic efforts are to be made to educate the child. There is a great tendency, naturally, for parents to indulge the little cripple, and thus exaggerate the mental and moral defects or perversions. From time to time, systematic courses of massage and electricity are advisable. The ordinary remedies are to be employed to combat the epilepsy. The various forms of talipes, when severe, may be treated by the orthopœdic surgeon, and sometimes accomplish much.

Lannelongue's operation of linear craniectomy, which has been so much discussed in the journals recently, and trephining have been recommended in some of these cases. When the secondary anatomical changes are considered, it is difficult to see how any good could result from operative measures. Yet I would advise them in certain cases where the epileptic attacks are frequent and the mental condition hopeless. Improvement, (of course, not cure) has followed the operation. If it offers even a small chance in an otherwise hopeless condition, it is justifiable. That if done, it is an empirical operation, is no valid argument against it. Are not many of our best remedies used empirically?

Starr's[1] analysis of twenty-three cases operated upon shows that improvement has resulted in nine cases, and that eight have died from the operation. The mortality is high, but the number of cases improved should encourage us to make further attempts. Unfortunately the pathological condition present in a given case cannot be predicted. With a growing knowledge of the morbid anatomy, we

may hope to more carefully select cases for operation in the future.

Physicians attending obstetrical cases should always bear in mind the possibility of meningeal hemorrhages in protacted, difficult, and instrumental labors. Certainly many of these cases are caused by difficult parturition. Yet in a given case of diplegia where forceps have been used to deliver the head, the physician should never express the opinion that the paralysis was caused by them, as he can never be certain; and may, in doing so, cast reflections upon some competent and wholly unblameworthy professional brother, and thus do him grave injustice.

Case 1. (Referred to me by Dr. Strœssley, of Allegheny, June 6, 1894). F. C., boy, eight years of age. Has healthy parents, and brothers and sisters. Mother had no difficulty at the time of his birth. When eight months old, and when teething, he was, for the first time in his life, seized with convulsions, lasting, with short intermissions, for three or four days. Prior to this time his health had been excellent. Up to the age of four years he had, according to his mother, a convulsion every time he cut a tooth. From four to six he was free from them. At six they returned, and have recurred every two or three months since. They are sometimes general, but oftener the movements are confined to the left side. He is sometimes conscious throughout a spell. He did not begin to walk until the age of four, when left-sided paralysis was very apparent. This has improved very much during the last four years, but is still apparent. The fingers are spastic. He was four years old before he began to talk. Even now he expresses his ideas in "baby talk," *e.g.*, "Me not let oo do," etc. The growth of his moral nature was greatly perverted and retarded. He exhibits lack of inhibitory development—often is cruel to animals and playmates; very imperfectly understands that it is wrong to cause pain or distress in others. When punished for acts of cruelty, he does not understand the reason for such punishment. He is easily diverted or amused by some trifle. He eats voraciously—often bolts food and then vomits afterwards.

Measurements at corresponding points.	Right.	Left.
	Arm—7½ in.	8 in.
	Leg—10½ in.	11 in.

This boy was treated by the ordinary remedies, efforts being specially made to direct his moral and mental training. No benefit resulted. I advised linear craniectomy, after carefully explaining the possible effects of the operation, but the parents decided against it. The boy was afterwards sent to the Elwyn institution for feeble minded children.

Case 2. (Sent to me by her physician from West Virginia, Sept. 25, 1893.) A. G., aged five years. Healthy parents, brothers and sisters. In the midst of perfect health, at the age of two years, she was seized with a left-sided convulsion which lasted four and one-half hours, following which she was unable to walk because of a left-sided paralysis, which became apparent upon the cessation of the convulsion. One month ago she was seized with a second convulsion, but it is not known whether it was general or not. There had been great improvement in the paralysis up to the time of this second fit, which fortunately was not followed by a relapse. But immediately after it, much moral perversion was noted, greatly to the chagrin of the parents, who are conscientious Christian people. At times she will kick, scream, spit and swear, with little or no provocation, The first day she was brought to my office she fought, screamed, and struck at her father viciously, all because she was vexed at some trifle.

Examination. There is no appreciable speech or mental defect. There is left-sided spastic hemiplegia—child walks with a decided limp, but quite well considering the motor impairment. There is spasm, and contractures of the arm, with athetoid movements of the fingers. Any attempts at fine movements of the fingers brings on a spasm which renders the hand quite useless. Ordinarily she does not attempt to use the right hand.

The parents had become over-indulgent with the child on account of her infirmity. A systematic and somewhat rigid course of mental and moral discipline was recommended and carried out, and resulted in much benefit to the child. Massage and electricity distinctly improved the nutrition of the affected side; and, to an appreciable extent, overcame the paralysis. The spasm and athetosis remained, being scarcely affected by the treatment.

Case 3. (Referred to me for opinion November 8, 1894, by Dr. Sowash, of

Irwin, Pa). Girl, five years of age. Born in a very severe and prolonged instrumental labor. She was paralyzed on right side since birth; and this palsy became noticeable gradually when she began to try to learn to walk. During the past six months the child has been seized with a number of "spells," during which she was momentarily paralyzed. Very recently she has fallen in several of these attacks. There have never been any convulsive movements.

Examination. Some, but not marked, mental defects. Distinct loss of power in right side—much more marked in arm than in leg. There are contractions at elbow, wrist and fingers. Flexes fingers; but cannot, at will, extend them, because of spasm. Athetoid movements in fingers. She cannot grasp small objects.

Measurements of limbs at corresponding points were as follows:

Calf, R.—7⅛ inches.	Thigh, R.—11 inches.
Calf, L.—7¾ inches.	Thigh, L.—12 inches.
Forearm, R.—5¾ in.	Upper arm. R.—5¾ in.
Forearm, L.—6¼ in.	Upper arm, L.—6 in.

No perversity of morals. Eats and sleeps well.

This case, apparently a birth palsy, is, contrary to the rule, a hemiplegic, and not a diplegic or a paraplegic.

I have advised careful, systematic education and occasional courses of massage and electricity. A six-weeks' course of Fowler's solution was also recommended.

Only a few days ago I received a letter from Dr. Sowash saying that there had been considerable improvement.

Case 4. (Referred to me by Dr. Dean, November 29, 1893.) Boy, aged fourteen. While teething he was paralyzed on left side. In 1888, when nine years old, he began to have epileptic seizures. These occurred first about every six or eight weeks. He now takes, and has for some months past, six or eight seizures a month. Usually two fits come close together. By far the greater number come on at night. He has light (*petit*), and severe (*grand*) attacks. During the light seizures, the left side only is affected, and he does not lose consciousness. The severe attacks do not differ from those of ordinary essential epilepsy.

Examination. Left arm and leg considably wasted, the former much more than the latter. No athetosis. Contractures not marked. He is dull, heavy mentally, presenting the picture commonly seen in essential epilepsy.

Anti-epileptic treatment resulted in considerably reducing the frequency of the fits. He was advised to use the paralytic arm as much as possible; and the mother was directed to employ systematic home discipline, and warned against over-indulging him. I fear little can be accomplished in the way of overcoming the paralysis or mental deficiency.

Case 5. (Referred to me by Dr. Jos. Dickson, November 15, 1894.) Girl, aged six. Parents healthy. One sister eight, and another four years old, in good health. Mother had no trouble in any of her confinements. Child in excellent health until time of present trouble.

September 1st last, she complained for two hours of very severe headache, following which she was seized with a convulsion lasting four and one half hours, during which consciousness was lost. The movements were confined to the right side, and were more severe in arm than leg. They left her suddenly and perfect consciousness returned. For twenty-four hours following this convulsion her eyes were strongly drawn to the left—the side of the lesion. During this time she did not sleep. In taking up the child in her arms twelve hours later, the mother noticed that the right side was flaccid—powerless. The power of speech, too, was absolutely gone. Only after five weeks did she begin to say a word. Three days later the right arm "drew up," flexed at elbow and wrist. There was spasm, or tetanic movement, lasting a few minutes at a time, for forty-eight hours. At the same time there were slight movements in right leg—flexed great toe. These leg movements were trifling compared with those in arm. Child screamed at each contraction of arm. Was conscious throughout the forty-eight hours. Immediately upon the cessation of these spasms, she went into a sound sleep—seemed comatose. This lasted five hours, and during it, hair was wet with sweat. Seemed very weak after this. Then she began to improve in general health, and has continued to do so up to the present time. To-day the mother says that the health of the child is as good, or better than it ever was. No convulsive seizures since the attacks described. The paralysis, after remaining

flaccid for two weeks, began to disappear, and slight contractures became noticeable. She has steadily gained in power and tone ever since.

Examination.—In general appearance a bright and healthy child. Some paralysis and contractures in right arm, which is flexed at elbow and wrist. Athetoid movements in fingers. Cannot voluntarily extend fingers or wrist. No evident moral or mental perversion. Power of speech limited to the utterance of the words "Mae," "A," "E," "Dummy," says these words perfectly. Does not use inarticulate sounds.

What anatomical change occurred on September 1st which would adequately account for the severe headache followed by right-sided convulsions, leaving the convulsed members paralyzed and power of speech abolished? Evidently it was an acute process. Embolism and hemorrhage, as we see them in the adult, produce very different symptoms. Would not meningeal hemorrhage, or meningoencephalitis, or both, most plausibly account for these symptoms?

The case is a typical one, and in many ways the most interesting one of this series.

The prognosis is, I believe, in view of the rapid recovery which has already taken place, good; *i. e.*, as these cases go. The complete aphasia, especially from the fact of its long continuance, is an interesting feature. As a rule, this symptom usually passes away very soon. Gowers[1] states that it rarely lasts a month or two. In this case it has, with slight improvement, persisted eleven weeks.

Systematic education, a course of massage and electricity and quinine and arsenic were advised.

Case 6. Girl[2], aged twenty-one, was in the midst of a fever of some sort when six years old, when she was suddenly seized with right hemiplegia. Her condition at present is as follows: Marked diminution in size of right arm and leg; hemiplegic gait; arm practically useless; athetoid movements in fingers. Singularly, there is no rigidity or contractures on the paralyzed side. She has two or three epileptic seizures each year. Mental condition fairly good.

Treatment in a case like this is almost hopeless.

1 Op. Cit., 457.

2 This case was exhibited before this society June 19, 1894. and was published in Pittsburg Medical Review of July, 1894, p. 219.

Case 7. (Referred to me by Dr. T. C. Christie, December 23, 1894). Girl, aged three years. Non-instrumental delivery. Mother in labor eighteen hours. Baby born "blue." Thirty-six hours after birth she was seized with a convulsion lasting with short intermissions nearly a whole day. Parents cannot remember whether it was one-sided or general.

A second convulsion occurred at the age of fourteen months. Since then, they have recurred every few weeks, always beginning on the right side. Sometimes the movements are confined to that side.

There is no appreciable paralysis; or mental or moral defect. Unconscious in all these convulsions.

Case.	1	2	3	4	5	6	7
Age at onset.	8 mos	2 yrs	Birth	8 mos	6 yrs	6 yrs	1¼ days
Mental condition.	Bad	Good	Slight	Dull	No change noticeable	Fair	Fair
Moral condition.	Bad	Bad	Good	Good		Good	Good
Paralysis.	Left H	Left H	R. H.	L. H.	R. H.	R. H.	None
Epilepsy.	Yes	Yes	Mal petite	Yes	Convulsions only at onset	Yes	Yes
Time between first and second convulsions.	.....	3 yrs	4 yrs	No long interval	.....	.....	Fourteen months
Athetosis.	.....	Yes	Yes	No	No	Yes	No

Several of the most prominent clinical features of these cases are shown in the above table.

All of these cases, except in birth palsies, began with convulsions, immediately followed by hemiplegia. Two began at eight months; one at two years; and two at six years. In only two cases (five and seven) was neither mental or moral deterioration noted. In all cases, excepting case five, epilepsy is present. In cases two, three and seven, intervals of three and four years and fourteen months respectively intervened between the initial and second convulsion. Athetosis is present in three cases; aphasia in one.

The series of cases is entirely too short a one upon which to base general conclusions; and can only be of value studied in connection with other series of cases.

CORRESPONDENCE.

COLD IN THE TREATMENT OF PNEUMONIA.

TO THE MEMBERS OF THE MEDICAL PROFESSION:

My last paper on *Ice-Cold Applications in Acute Pneumonia* gives a record of seventy-four cases so treated, and only two deaths. Being desirous of making a full collective report on this subject, I take the liberty of asking those who have tested this measure to kindly give me the result of their experience with it. Full credit will be given to each correspondent in the report which I hope to publish.

THOMAS J. MAYS, M.D.
1829 Spruce St., Philadelphia.

RESUSCITATION OF STILL-BORN INFANT BY RHYTHMICAL TRACTIONS ON THE TONGUE.

EDITOR MEDICAL AND SURGICAL REPORTER:

On January 21st last, I was called in consultation to attend Mrs. G., aged twenty-five, in her second confinement. She had been in labor some thirty-six hours without progress. The pelvis was somewhat narrowed in the conjugate diameters. Instruments were used, and after forty minutes delivery was accomplished.

We saw the condition was serious for the child and immediatly pressed the blood from the cord towards the umbilicus; tied and cut it at once and removed the mucus. We used the usual water methods; also tried friction to the spine, back and soles of the feet; also artificial respiration. After trying for ten minutes we saw that our efforts in this line were utterly useless. I suggested "Rhythmical traction on the tongue," and requested my colleague to procure from his pocket-case a small artery forcep which was placed on the tip of the tongue. The tractions were made so that about twenty to twenty-four were produced each minute. We were very anxious; to our surprise in about six minutes the little one's nostrils began to flutter and in less than ten minutes respirations were established and normal in every particular.

A. ERSKINE, M.D.
Rogers City, Mich.

CHINESE CRUELTY.

Some four years ago I spent four days in Canton, the metropolis of southern China, on a special mission to investigate Chinese justice, and the results surpassed my most ghastly anticipation.

What I witnessed was nothing unusual, and is the daily practice of the country, but I am compelled to tone down the details to make them presentable for publication. Nothing but the strongest spirit of inquiry, supported by an iron resolution, carried me through the horrors of those days, and for weeks afterward I suffered from perpetual nightmare.

The place of execution, or "Matou," as it is called by the Chinese, is a filthy yard, long and narrow, like a blind alley, and, singularly enough, it is used as a potter's field when not required for execution.

On a cold January afternoon I proceeded thither to witness the final release of a batch of poor wretches who had already undergone a prolonged course of torture.

On this occasion the death-squad consists of thirteen, who are tightly bound hand and foot and carried in, huddled up

in baskets slung on a bamboo between two coolies. On arriving at the center of the ground these living loads are pitched out unceremoniously, and immediately seized by the executioner and his assistants, who arrange them in two lines in a kneeling position.

At a nod from the presiding mandarian, and with incredible swiftness, the butchery commences. The assistant seizes the first victim by the shoulders from behind, while the executioner steps up to his left side, armed with an enormously heavy, short sword with a broad blade and razor-like edge. Without any compulsion, the victim, still kneeling, bends his head forward, and almost instantaneously it leaps from his body, severed by one swift stroke. The assistant pushes the trunk over forward, and a shrill burst of approving "Hi-yahs" goes up from the crowd.

After the uncertain and clumsy operations of the mediæval headsman, one had been led to suppose that a human head required a great deal of severance; but so adept are the Chinese executioners that they appear to display no more effort or emotion in cutting off a head than they would in lopping a poppy from its stalk.

With fearful rapidity the slaughter proceeds, and not five seconds elapse between the fall of each head. One unerring stroke ends each life, and the victims are so arranged that each can witness the fate of all those in front of him before his turn comes.

The crowd is now in the most jovial humor, and signifies its light-hearted enjoyment by ribald chaff at the expense of the remaining victims, who frequently retort defiantly, and exhibit the most stolid indifference to their fate.

Suddenly a burst of merriment arises in one corner. A portly merchant has approached too near, and his long white coat is splashed with blood. How the bystanders laugh! Was there ever such a good joke!

The last few heads are falling now, when my hands is plucked by an excited youngster of ten, dancing with delight, who cries, eagerly, "Ho-ta?" (Isn't it beautiful?) I repress a fierce desire to throttle him, and in a few seconds all is over. Justice is vindicated, and the crowd quickly disperses, all but the city gamins, who remain behind to rehearse the whole proceedings and to skylark with the bodies.

Horrible though the sight has been, death has, at any rate, been swift and merciful, but another day the supreme horror of Chinese justice is revealed to us.

For certain offenders, notably parricides and women who kill their husbands, the penalty is the "Ling-chee," or "thousands cuts." This is too ghastly for detailed description, but suffice it to say that the victim is first crucified to a low cross, and then slowly sliced to pieces with a knife.

So skilful is the executioner that although his victim soon becomes almost unrecognizable as a human being, yet no vital wound is inflicted till perhaps half an hour of this torture has elapsed, when the agony is ended by decapitation.

So superior an entertainment as this is naturally rewarded by a full house, and even greater merriment prevails than at mere head-chopping displays, which savor somewhat of monotony to the *blasé* Cantonese.—*Harper's Weekly.*

Cystitis in the Female, with Special Reference to Treatment.

John C. Hersler, Ph.G., M.D., *Univ. Med. Mag.* The chief indications for treatment are:

1. To remove any discoverable source or sources of irritation which act through the medium of the urine. This may be affected by a milk diet, and a discontinuance of the use of acids, pepper, etc. Any mechanical source of vesical irritation should receive appropriate treatment.

2. The urine should be rendered bland by the use of a milk diet; the ingestion of considerable quantities of water, the administration of potassium citrate, if the urine be too acid, or of boric acid if it be alkaline.

3. Pelvic congestion should be relieved by hot vaginal douches, placing the patient in the knee-chest position; and the correction of constipation.

4. The inflamed cystic mucous membrane may be relieved by the administration of boric acid, salol, ol. santal, copaiba, or creosote by mouth; or the use of injections of boric acid, carbolic acid, of nitrate of silver in suitable strengths.

5. The patient's general health should be improved by tonics, etc.

6. Rest in bed, especially in all acute cases, is absolutely imperative.

THE MEDICAL AND SURGICAL REPORTER

ISSUED EVERY SATURDAY

Address all communications to P. O. Box 843, Philadelphia, Pa.

HAROLD H. KYNETT, A.M., M.D.
Editor.

RODERIC C. PENFIELD
Publisher.

Editorial Offices, 1026 Arch Street, Philadelphia, Pa.

Entered as second-class matter at Asbury Park, N. J.

TERMS:—Three Dollars a year in advance. Sent four months on trial for $1.00.

REMITTANCES should be made payable to the Publisher only, and should be made by Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We invite contributions of value to the profession, and if published originally in THE REPORTER such will be paid for at liberal rates, or a limited number of copies of THE REPORTER will be supplied, as the author may elect. Hereafter where reprints are desired writers are requested to make a note of that fact on the first page of the MS., but must order reprints directly from the publisher, who will supply the same at cost rates. Contributors should inclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, APRIL 18, 1895.

EDITORIAL.

THE TREATMENT OF ECZEMA.

Eczema, a term which has brought despair to the doctor and dollars to the quack, has long been the resort of those seeking a name for any skin eruption unknown to the observer. Even in its proper and limited application, eczema, which in protean form has always tormented mankind, is a subject about which medical science knows but little and understands less. Nevertheless, for a man who classifies all skin diseases as eczema, and not eczema (the latter class including the few eruptions he is familiar with, *e.g.*, those of the exanthemata, etc., etc.), there is much to learn.

Eczema was made the subject of a special discussion in the Section of Dermatology, at the meeting of the British Medical Association last year, and the report of the discussion as given in the *British Medical Journal*, contains suggestions of much value, and, as well, discovers the modern views of English dermatologists. Mr. Malcolm Morris, who opened the discussion, was particularly satisfactory in the expression of his opinions.

He assumes that in all cases eczematous lesions should be cured as rapidly and as thoroughly as the therapeutic resources at command will allow. He does not look upon a patch of eczema as a kind of overflow pipe for the escape of "depraved humors," which would otherwise—to borrow the language of popular pathology—"settle in" the lungs or other internal organs, a superstition that still survives in quarters not open to the least suspicion of scientific heterodoxy.

Opinions differ as to whether the disease is, in origin, constitutional or local. Probably the constitutional element is in most cases altogether secondary, the lesion being chiefly the result of parasitic irritation. A constitutional dyscrasia—such as gout, glycosuria, kidney disease, rheumatism, rickets, or scrofula—no doubt has a serious modifying influence on the local process, intensifying it, and preventing or retarding recovery, but the *causa causans* is, in the majority of cases, the action of

micro-organisms. Seborrhœa is a very common precursor of eczema, in fact it prepares the way by making the skin vulnerable by microbes. Unna goes too far when he teaches that eczema is always and in all cases the result of microbic action. Seborrhœic eczema is always parasitic in origin, but not all eczemas are seborrhœic. Often the disease arises on perfectly healthy skin, apparently as the result of some disturbance of the nervous system, caused, it may be, by mental shock, strain or depression, by the action of the cold, or by reflex irritation from the uterus, stomach, intestine, etc. Even in cases in which disordered innervation seems to be the starting point, it is probable that the parasitic factor plays a leading part in the process; the weakening or suspension of nervous control—in other words, the inhibition of trophic influence, in certain parts of the skin creating weak points through which the micro-organisms normally present on the surface of the skin, can penetrate into the deeper layers.

The treatment of eczema must in every case be carefully adapted to the special indications present. There is no general therapeutic formula applicable to all cases; it is not the abstract name but the concrete disease that has to be treated, and not the disease alone, but the patient, with his peculiarities of structure and constitution, behind it.

In the treatment of eczema diet has no influence except indirectly. Thus, if a constitutional condition such as gout or diabetes underlie the eczematous process, of course the dietetic restrictions indicated in the circumstances are called for. Again, if the lesions are of an acutely inflammatory type, the diet should be limited in quantity, and bland and non-stimulating in quality. Apart from these indications there is no reason to think that restrictions of diet have any good effect; on the contrary, a "lowering" regimen may do positive harm by weakening the patient. The true principle in the management of eczema, as far as diet is concerned, is to let the patient take such food as he finds most suitable to his digestive powers. Anything which disorders the gastro-intestinal tract, or which causes acidity, insomnia, flatulence, palpitation, or vasomotor disturbance must be avoided. The same principle applies to drinks; but here, it is almost needless to add, strict moderation in quantity is necessary. In acute forms beer is contraindicated, as are all other beverages likely to cause flushing. There need be no restrictions in the use of tea or coffee unless these beverages are contraindicated by definite ill-effects on the digestion or nervous system. In short, so far as diet is concerned in eczema, "A man's owne observation, what he findes good of and what he findes hurt of, is the best physicke to preserve health."

As a general rule the less internal medication there is in eczema the better. If a constitutional dyscrasia underlie the skin affection it must be treated on the ordinary principles of medicine; if the neurotic element be pronounced remedies directed to the restoration of the nervous tone are indicated; if the patient be broken down by want of sleep and the exhaustion consequent upon prolonged suffering, sedatives and general tonics will be required; similarly if there be disorder of the digestive apparatus this must be rectified by appropriate measures. Where, however, there are no definite indications of the kind referred to, internal medication is not only useless, but positively injurious by disordering the digestion. In an ordinary chronic eczema, where the patient's health appears to be unaffected, and there is no reason to suspect constitutional dyscrasia, trust entirely to local treatment. Where internal remedies are given the selection of the particular drugs employed must be governed by definite indications. When the lesions are acutely inflammatory in character, antimony is valuable, giving mx to xiiij of the vinum antimoniale, repeating the dose in an hour, and, if need be, again two hours later. The interval between the administrations is gradually increased, the dose being at the same time reduced till one of m vj is reached. This should be given thrice in the twenty-four hours until a distinct subsidence in the intensity of the inflammation becomes manifest. The indication for antimony is the presence of arterial tension; on the other hand, depression is a positive contraindication of this drug. If a neurotic element is clearly present in the case, sedatives and nerve tonics must be combined with local treatment. In such cases the sheet anchor is opium, under the influence of which the patient should be kept almost continuously until the nerve storm sub-

sides. In such cases, often, it is of great advantage to begin the treatment with a full dose of calomel, and, afterwards, the constipating effect of the opium should be counteracted by the administration of a saline aperient every morning. If opium disagrees, some other sedative, such as sulphonal, must be substituted. The indication for the use of sedatives is great nervous excitement, accompanied by sleeplessness.

If, on the other hand, the neurotic element shows itself in the form of depression nerve tonics are indicated; of these the most useful, perhaps, is quinine. This may advantageously be combined with opium. If there be much discharge, belladonna may usefully be combined with the quinine. Phosphorus is of great value in counteracting nervous depression and strychnine also often does good. Arsenic, though undoubtedly useful in some cases, is far from being a specific in eczema, and if injudiciously used will do harm instead of good. The indication for its use is deficiency of nerve force combined with absence of acute inflammation in the lesions. If the eruption be of an actively inflammatory type arsenic is positively contra-indicated. If the disease process shows a marked tendency to frequent exacerbations, ergotin may be useful by the control which it exercises over the vasomotor apparatus.

Malnutrition, weakness, and anæmia are indications for cod-liver oil, and general tonic treatment on ordinary principles. Iron, however, is contra-indicated by the presence of acute inflammation; in such cases it adds fuel to the flame. Any source of peripheral irritation discovered, must, if possible, be removed. In women menstrual derangement or uterine disease must be remedied, and hysteria or the disturbances incident to the climacteric must be combated by such remedies as musk, valerian, etc.

It is impossible here to go into the details of the local treatment of eczema of different forms and in different situations. Speaking generally treat every case as if it were of parasitic origin. Even if micoorganisms are not the exciting agents in the causation of the process in all cases, parasitic irritation always comes into play sooner or later as a secondary factor, and requires to be appropriately dealt with. The objects aimed at in the local treatment of eczema are, first, to destroy micro-organisms: secondly, to protect the inflamed surface from the air and further microbic invasion; thirdly, to soothe irritation. The general principles which guide in the application of local remedies are, first, to temper the strength of the remedy to the tolerance of the patient's skin; and, secondly, to keep the remedy continuously in contact with the affected parts.

The best remedy for local use in dry, chronic eczema, especially of seborrhœic origin is sulphur, and next to that resorcin. These drugs not only destroy the micro-organisms on the surface of the skin, but give rise to exfoliation of the horny layer, and bring away with it the microbes which have penetrated to the deeper parts of the epidermis. Morris uses at first, an ointment composed of 10 grains of precipitated sulphur, or the same quantity or resorcin in ʒj of zinc ointment or some other soothing application; the amount of the antiparasitic agent is increased very gradually. When the inflammation is acute, ichthyol is particularly useful, as it is a vascular sedative as well as a parasiticide. Other antiparasitic remedies which are of service as applications in eczema are salicylic acid, white precipitate, boracic and carbolic acid. Use them with cooling "creams" as vehicles when there is much irritation. For the continuous application of local remedies in limited areas of chronic character Morris has found nothing so useful as the plaster mulls devised by Unna, those he finds most generally useful being carbolic acid and mercury, and oxide of zinc.

When discharge is profuse, wash the part with a weak solution of boracic acid, afterwards drying it with muslin bags containing starch and powdered boracic acid, or with flour mixed with a small quantity of the same antiseptic. If itching is troublesome, weak lotions of carbolic acid or tar are most beneficial. For very persistent chronic eczema of the flexures he has frequently had good results from chrysarobin.

Morris sums up the principles on which the local treatment of eczema should be conducted as follows: Soothe when the inflammatory process is acute; stimulate when it is chronic; and in either case keep the parts under the continuous influence

of antiseptics and parasiticides, of a strength carefully regulated in accordance with the intensity of the disease and the sensitiveness of the skin.

To guard against recurrences of the disease, change of climate is often productive of good especially if accompanied by complete rest of mind as well as body. There are no special indications in respect of climate except that eczema, being a catarrhal disease, it will be well to avoid climates which are apt to produce catarrh of any kind. A too bracing climate—especially places where the northeast wind holds sway—should be avoided. The same may be said of sea air. As regards altitude, there is no general rule; as in the case of climate, it is largely a matter of idiosyncrasy. The true principle is to discover what suits the patient. After all, it is the change that is the most powerful alterative. Sea bathing very often produces a recurrence of the disease, but it sometimes undoubtedly counteracts the tendency to relapse.

Morris sums up his own conclusions as to the utility of springs in the following propositions:

"1. No spring known to me has any specific action on eczema.

"2. Such virtue as sulphur waters externally applied possess is due chiefly to the parasiticide action and partly to the temperature at which they are applied.

"3. Such virtue as sulphur, chalybeate, or arsenical waters possess when taken internally is due to their action in quickening the processes of metabolism, increasing the number of red corpuscles in the blood, and giving tone to the nervous system."

ABSTRACTS.

MODERN TREATMENT OF ABORTION.

JAMES R. LATHAM, M.D.

In this paper it is intended to speak of the management of all cases of premature delivery of the products of conception, up to the fourth month. In order that my remarks may be the more easily followed, it seems well that I should premise my discourse by a few words in reference to the anatomy of the uterus and its appendages, and also to say something of the physiology of conception. By this plan we may the better be able to appreciate those changes that take place in the uterine wall and in the appendages and which have so much to do in the destruction or preservation of the ovum in its beginning of that life that, once begun, goes on to birth.

The uterus, as we all know, is suspended in the pelvic cavity by its ligaments; its most important suspensory ligament being the broad ligament. Imbedded in this and connected with the uterus are the fallopian tubes and at their distal terminations lie the ovaries. It is in the ovaries that we have the ovum first appearing through rupture of a graffian follicle, thence taking its way through the fallopian tubes, either to be fertilized by contact with the spermatozoon or to be carried off with the menstrual blood at the first following menstruation.

The fallopian tube appears to be where the meeting of the ovum with the principle that is to render it productive takes place, and a great deal depends upon just where this meeting occurs. For it may happen that the contact is made before the ovum is fully discharged from the corpus luteum and in such a case cause extra-uterine pregnancy.

Now let us imagine that an ovum has liberated itself from its bed in the corpus luteum, reached the fallopian tube, met and been vivified in some subtle way by contact with the spermatozoon. It now finds its way out into the uterine cavity and attaches itself to the mucous membrane lining this organ. We now find

changes commencing in both its own condition and in the structure of the surface to which it is attached.

When the ovum first enters the cavity of the uterus and becomes attached to its membrane, its cell wall sends out numerous prolongations; these hold the egg in its position and facilitate its nourishment from the blood-vessels of the uterine mucous membrane. There is also an increase in the blood supply in the uterine wall corresponding to the place of attachment.

This state of things continues until about the third month, when the chorion and its villi atrophy and finally disappear, except at that portion attached to the uterine wall. Here the villi develop still further and the placenta is formed.

It is the fourth month, however, before the placenta can be fairly differentiated from the rest of the chorion; and it is the time previous to this that I will include in speaking of cases as abortive. So we have in all cases up to the fourth month the following intra-uterine condition:

An ovum attached by villi to a spot on the lining mucous membrane of the uterus with a connection between it and the blood supply of the uterine wall, and an increased blood supply in the uterine wall at that place not only, but an enlargement of the whole organ and a more than ordinary amount of blood corresponding in amount to the length of time of its attachment. Now if by reason of a sudden jar, as by falling and striking on the buttocks or feet, or in any way so as to transmit the shock to the uterus, we may have a rupture of the villi that attach the ovum to the mucous membrane, and the chorion being thus deprived of its means of nutrition, the ovum is cast off.

Sometimes it happens that the ovum being detached at one point becomes attached at another and the development goes on; the only sign of this being a slight discharge of blood from the lacerated spot per vaginam, and the continuation of pregnancy.

Thus violence may be, and is, one of the causes of abortion. In speaking of the causes of abortion I shall not attempt to mention all the conditions that may cause it, but will confine myself to those that are most common and with which we have to deal in our ordinary practice.

Now there is, I have found, a frequent cause for abortions in the abnormal condition of the intra-uterine mucous membrane caused by endometritis. If we study the changes in the structure of the endometrium that this condition induces, we can readily understand why the ovum, even after it has become lodged, fails to so firmly affix itself as to be able to withstand the slightest assault upon its position.

The surface of the mucous membrane is changed both in the chronic and acute forms of the disease. In the first we have the mucous lining smooth and deprived of epithelium; in the second it is roughened and congested. There is a change also in the epithelium, it being now of the basement variety instead of cylindrical or ciliated. It seems to me that here we have one of the great causes of non-retention of the ovule.

Let me quote a few words from Thomas' description of the condition of the lining of the uterine cavity in endometritis. In his description he is in agreement with Scanzoni. He says: "The mucous lining of the uterine body was in two cases quite smooth and to a great extent deprived of epithelium, while in a third it was roughened and presented points where the enlarged blood-vessels created a number of reddish spots." It is highly probable, too, that in most cases of recent origin these pathological appearances would not be found to exist, but in place of them a thickened, congested and florid appearance would present itself.

There is another condition whose existence has been so coincident with abortion as to compel interference for its relief; that is, lacerations of the cervix. I am not prepared to state how this exerts its influence, but its repair has often caused a cessation of abortions. It may be that the cicatricial plug in base of tear exerts a nervous influence, but I am more inclined to believe its bad influence to be due to its keeping up an endometritis.

Uterine displacements are another cause. I do not believe that these displacements are per se a cause of abortion, as I know of cases where pregnancy has gone on to a successful termination coincident with most marked displacement. It is only in such cases where the displacement has caused interference with the circulation in the organ, and where congestion has changed the normal condition of the

mucous membranes, that we may expect non-retention to occur.

There are causes due to conditions of the mother's blood affecting the ovule. Among these we may include syphilis, the infectious diseases, powerful emotions, etc.

There is also a condition spoken of as a "habit of aborting." We have all known of such cases where a woman will habitually abort after about the same period of utero-gestation, from no other apparent cause but the nervous effect of "habit." I strongly suspect, however, that in most of these cases, upon thorough examination, it will be found that the uterine mucous membrane is not in a condition to sustain nutrition in the attached ovum.

TREATMENT.

The treatment may be divided in two classes: expectant and preventive, in those cases where the ovule has not been cast out through the os; and radical, where we have reason to believe that the ovule has become completely detached and has passed through the os.

In the first class of cases we will be sent for to see a woman who anxiously informs us that, after having missed her menstruation for a month or two and believing herself pregnant, she has noticed slight pains in her pelvic region and a slight show of blood on her linen. She may or may not give a history of extra activity just prior to the occurrence. It is well now to inquire about the blood flow, its amount, and to inquire closely whether she has felt anything pass before the visible discharge of blood, for often the ovule will become detached and escape while the woman is on her feet, and she may remember a slight feeling of shock caused by the dilatation of the os during its passage. But failing in this, we should direct the woman to at once relieve herself of closely-fitting garments and to assume a recumbent position preferably in bed. We should endeavor to relieve her anxiety by encouraging words and administer a good dose of opium or morphine to relieve the uterine irritability. She should remain in bed closely until we are assured that, by the immediate cessation of the blood flow, we are on the right track. She should then remain in bed until there has been time enough for the ovule to reattach itself either wholly or in part; meanwhile we should give her just enough opium to quiet uterine sensibility.

If, however, we should find a greater amount of hemorrhage on our first visit, (and I know of no rule to guide us—a man in this must use his judgment,) and we conclude that palliative measures are useless, we then take such measures as will empty the uterus most thoroughly, to prevent useless loss of blood and subsequent septic infection by retained products of conception. In doing this we first anesthetize the patient if she be nervous and excitable. Anesthesia is not, however, always necessary. We then thoroughly cleanse the external genitals and the vagina by washing, first with soap and warm water, and then with bichloride solution 1 to 2,000. We should thereupon fully dilate the cervix with a steel dilator, and then scrape the lining wall of the uterus with a curette, until we are satisfied that we have removed all the retained products. Now we should wash out the cavity with a hot bichloride solution, 1 to 2,000, making sure that, there is plenty of room through the cervix for an easy return flow. If we have well emptied the uterus of the membranes we will shortly have the water returning clear of blood. We now fix the cervix with a tenaculum and proceed to introduce into the uterine cavity a strip of antiseptic gauze about two inches wide, and this we pack in until the cavity is moderately full, leaving about an inch of the gauze protruding through the cervix into the vagina. The vagina is also filled with gauze. The speculum is withdrawn, and the gauze left in position for two or three days, the woman remaining in bed. If everything goes well and there has been no great pain, no discharge through the gauze, and no rise in temperature, we may on the third day withdraw the gauze first from the vagina, wash out the vagina with the bichloride solution and dry it with absorbent cotton; now we may proceed to withdraw the strip of gauze from the uterine cavity. Often we will find a large portion of it forced out into the vagina by the uterine contraction. Taking hold of it with the dressing forceps we gently make traction and find it will easily come out. We now repack the vagina, after flushing it again with the bichloride solution, leaving this in for a day; we can then withdraw this and leave the case to recover without more active local interfer-

ence. Sometimes we find, however, that there is more or less hemorrhage following the first packing. We know by this that there is something retained and another curettage is necessary. This should be done under ether with the same aseptic precautions, packing as before. If, however, the primary operation is thoroughly done, I have seldom found it necessary to do a second operation, unless, indeed, there be some deeper reason for a continued hemorrhage. The advantage of the gauze packing is that it acts as an irritant to the uterine cavity, causing contractions, and also as an admirable method of drainage. There will be found some difficulty in introducing the gauze until practice has improved the novice's method. Pull down the cervix gently with tenaculum to straighten the uterine canal; then introduce with instrument specially designed, called a gun-screw applicator. By this treatment I have avoided all dangers of metritis, endometritis, etc., and had the woman practically well on the fourth day.

It will, perhaps, be noticed that I have made no mention of abortion produced by criminal means. In such cases, should there have been no traumatism, the treatment is the same. In such cases, however, we often do not see them until some time after the death of the ovum, and the greatest care is necessary to prevent the effects of septic infection. — *American Medico-Surgical Bulletin.*

THE SKUNK AS A SOURCE OF RABIES.

W. Wade, (*The American Naturalist*, March 1895,) writes:

Doubtless many have heard the story that the bite of a skunk can convey rabies. I first heard it some years since in the form of an inquiry from a distinguished physician in London; and to an old fox-hunter, who has known of hounds by the dozens being skunk-bitten with no subsequent ill-effects, the story was exceedingly ridiculous. But when my friend stated that Dr. John H. Janeway, a surgeon in the U. S. Army, was said to have given the story his endorsement in a New York medical journal, the matter became immediately worthy of most serious consideration, my friend suggesting that there might have been something in the environments of the skunk, at the time Dr. Janeway wrote, to account for the marvelous exception, and I at once set to work to investigate what was known on the matter. Immediately I was involved in a maze of contradictions, no two stories agreeing. No belief of the story could be found anywhere but in Texas, the Indian Territory, and adjacent districts. Even in southern Kansas no such belief was found. Then in some cases it was the skunk, *Sui generis*, that had this power, while again it was only one particular variety of the skunk, the "hydrophobia cat." The vulgar idea was that any skunk, rabid or non-rabid, was capable of conveying infection of rabies, while more intelligent observers held that only a rabid skunk had this power, but even these seemed to hold that there was special danger of skunks being rabid, or that the virus conveyed by their bite was more potent than that from any other rabid animal. Again, instances were cited of men dying as the result of a skunk bite; in one case after many months of lingering illness, which most certainly could not be rabies, or another case of a man exhibiting rabic symptoms after a skunk bite but recovering on copious bleeding, and evidently there was no rabies *there*. Again, the New York *Sun*, about six months since, had a most blood-curdling story of many soldiers in Mississippi dying from the bite of a skunk, and the deaths spread over a period of several months, a marvelously long-lived skunk to live a month after rabies had developed to the stage of being communicable, and inquiries in Mississippi showed that no fatal case of skunk bite was ever known there, although skunks were sometimes kept as vermin killers.

Now remember that this story drew all the weight it could have from the allegation that *Dr. Janeway had endorsed it*, and remember further, that the belief was that the skunk, *at present*, had this power. At last I was able to get Dr. Janeway's

paper, which was published in the *Medical Record* of New York, March 13, 1875, and a more ridiculous breaking down of a ridiculous myth I never saw.

It appears that Dr. Janeway was stationed at Fort Hays, Kansas, when an epidemic of rabies broke out in the surrounding country, and his paper in the *Medical Record* was based on his report to the Surgeon-General of the U. S. Army; and in a letter to me he says that after writing this paper to the *Medical Record*, he endeavored to trace the origin of the epidemic, and if he remembers aright, found by inquiries that it was first noticed in the northern tier of Texas counties, and travelled north by west to the Fort Hays reservation.

So far from Dr. Janeway stating that *any* skunk could convey rabies, he distinctly refuted the assertions of some clergyman to this effect, citing instances of dogs and men being bitten by a skunk without injury (and one case wherein one person died and two escaped unhurt from the bite of the same rabid wolf). Dr. Janeway gives a very qualified adhesion to the belief that the bite of a rabid skunk was fatal in a larger proportion of instances than the bite of other animals, and thus explains it:

"That more cases, proportionally, may result fatally from the bite of this animal than from the bite of rabid dogs and wolves, is probably, if not actually, the case; still there are obvious reasons for it to be so. An animal, nocturnal in its habits, generally timid, but armed with a powerful battery to resist any injury or affront; one that will not bite in defence until the secretion provided for it by nature is exhausted, loses that secretion by the disease. It is a well authenticated fact that rabid skunks are entirely free from the odor so characteristic of these animals, which could not occur if the secretion were not exhausted; and forgetting its normal timidity, will attack any person or animal it may come in contact with, biting the most exposed parts of the body, the alæ of the nose, the lobe of the ear, the thumb or one of the fingers, and passes on. Here is probably the reason these bites are more fatal than those of other animals—always in a vascular part not protected by clothing—which prevents by wiping away the poisonous saliva, from the fierce attacks of the mad dog or wolf and thus saves the life of the one bitten." This is very intelligible and reasonable.

Then, even those who believe that only the *rabid* skunk conveys rabies by its bite, and that the skunk is more susceptible to rabies than other animals, seem to believe that this is the *present* state of affairs that skunk bites are *now* peculiarly dangerous. Now Dr. Janeway expressly says that rabies was epidemic in Texas when he made his observations on the disease in skunks and other animals, thus: "Rabies Mephitica, like Rabies Canina, is evidently epidemical, no cases of it having been reported previous to 1870 in this region;" and in his letter to me of December 15th, he says: "The epidemic was short-lived, no cases that I heard of occurring the next year. A great number of skunks must have succumbed to the disease, as they were less plentiful after that season;" and further, a surgeon in the U. S. Army, now stationed at Fort Bliss, writes me: "I have served five years in Texas, four in the Indian Territory, four in Dakota and other places where skunks abound; during this time, I have never known anyone to be bitten by the animal referred to. The bite of a rabid skunk will, of course, produce the disease, and in other instances where serious trouble has followed this occurrence, I am of the opinion that the symptoms are due to septic poisoning. The bite or scratch of almost any animal is more or less poisonous from the bacteria always present on the teeth and claws. Even *human saliva* is poisonous when injected into certain animals, as has been conclusively proven by our present Surgeon-General."

Now I have never been able to get hold of anybody, in Texas or elsewhere (of course, other than Dr. Janeway), who had ever seen a case of skunk rabies, or who had anything like definite evidence on the matter; "I have heard it," "It is generally believed," etc., has been the utmost limit of statements on this point. Some believe it themselves, but are completely "out of reasons for it." One well-known naturalist puts his views on the question in this form:

"1st. The bite of the skunk often communicates rabies and death.

"2nd. Skunk rabies kills more people than dog or wolf rabies.

"3rd. To be bitten by a skunk is to risk a terrible death.

"4th. Beware of all skunks, for one can never tell when a rabid skunk will come along."

And perhaps this expresses intelligent, but incorrect, belief on the subject as well and accurately as it can be done. Therefore let us examine what the actual evidence on the matter is. Dr. Janeway, like any intelligent physician would do, refutes the self-originating idea of rabies in the skunk (and parenthetically, a physician with all the light of recent knowledge as to rabies, tells me that Dr. Janeway's conclusions are singularly sound and conclusive, when the deficiency of exact knowledge on the disease, then the case, is taken into consideration). That idea is such utter nonsense that only the erroneous assertion of Dr. Janeway's endorsement entitled it to a second thought. Then Dr. Janeway positively says in his paper in *The Medical Record* that rabies was epidemic when he made his observations, and he adds in his letter to me that this epidemic was so transient that in one year it had passed away. (Scientific men have suggested, as the probable explanation of such epidemics wearing themselves out, that the subjects die off faster than they can communicate the disease to fresh victims). A surgeon in what is now the central seat of belief in the "skunk-rabies" delusion has not heard of a case in the nine years he has been in this district. A physician in southern Kansas, not remote from Fort Hays, wrote me that he had never heard of the skunk-rabies belief, that skunks were not uncommon as pets in his neighborhood (deprived of their scent powers, I believe). From Southern Colorado to North Dakota, I can find no belief prevailing in this myth. Then it all amounts to this: Dr. Janeway made careful observations twenty years ago, during an epidemic, he says this epidemic lasted only a year. A surgeon in the U. S. Army tells us that the ill effects that do sometimes follow skunk bites may readily be accounted for as septic poisoning, just as might result from the bite of a fly or the scratch of a tiger's claws. Therefore, my answers to the points I quote from a well-known naturalist are:

1st. The bite of a non-rabid skunk can communicate no rabies, and it is beyond question that rabid skunks are exceedingly rare, if found at all. In no part of this country were rabid skunks ever reported save during a short period of epidemic rabies in Texas and Kansas.

2nd. Skunk rabies perhaps killed more people in Texas, etc., during a certain period than canine rabies, but because sleeping in the open air ("camping") was common there and the skunks readily encountered men. I think that statistics would show that dog and wolf rabies has caused twenty times the deaths that skunk rabies has.

3rd. To be bitten by a skunk is to risk contracting septic poisoning, I believe a terrible death, and the bite of a fly is said to have produced the same disease, and I think a butcher cutting himself with his butchering knife is in the same danger, but none of them risk rabies.

4th. Well, yes, "beware of all skunks" on "smelling" grounds, but it might as well be said "beware of all dogs, for one can never tell when a rabid dog may come along."

Minimizing dangers that are real is most dangerous and reprehensible, but making spooks of mist is but little less so. Some boy reads or hears that skunk-bite "will make a man go mad," some day he does get a skunk bite, and we can easily imagine the terrors he suffers, and all from the veriest bosh.

The subject of rabies is now loaded down with quite enough rubbish, such as the absurd notion that if a healthy dog bites a man and subsequently becomes rabid, the man will "go mad" also, and adding another piece of bosh is more than we ought to be afflicted with.

I fear I may just now be venturing beyond my depth, and therefore, I wish the following to be taken entirely as suggestive: Must it not have been under very exceptional circumstances that rabies was first introduced among skunks in Texas? It surely is true that rabies is especially a disease of the canidæ, dogs, wolves and (?) foxes. Now a rabid dog (and I suppose, a rabid wolf), in the stage of the disease in which communication of infection is possible, is about destitute of intelligence. It runs blindly, wildly, and without purpose. The skunk is both nocturnal and retiring, and would easily and naturally get out of the way of a rabid dog "on the run." In Europe where rabies is more

prevalent than in this country, the polecat and other animals, relatives and of similar habits to the skunk, are never known to be rabid. So how in the world did the first rabid skunk become so? Unquestionably there were rabid skunks, and almost certainly there was a first one which communicated the disease to its fellows, and does it not seem certain that this first victim became infected under most peculiar and exceptional circumstances, and that these are not likely to be repeated? And, as a final wind-up, What is all this pother about? There is not a particle of evidence that skunk bites are particularly dangerous, and while nobody need wish for such a bite, if he does get it he need not worry himself about any danger of rabies.

THE DURATION OF THE CONTAGIOUSNESS OF DIPHTHERIA.

The *Journal des praticiens* contains an article in which the writer remarks that this question is the subject of much controversy. A young physician, M. Tézenas, recently collected sixty observations of patients who were attacked with characteristic diphtheria, and he divided these cases into three series, and made a bacteriological examination of the products taken from the bucco pharyngeal mucous membrane and from the nasal discharge. The following results were obtained: In the first series, in forty-four cases, the mucous membrane did not present any false membranes and there was no nasal discharge. On bacteriological examination, the cultures showed no bacilli, except in three or four cases where Lœffler's bacillus disappeared after four days. In the second series, in five cases the mucous membrane was divested of its false membranes and the nasal discharge dried up. Nevertheless, Lœffler's bacillus persisted from twelve to twenty-eight days. In the third series, in eleven cases the nasal discharge persisted, and the cultures with this discharge were positive, although those of the products drawn from the bucco-pharyngeal mucous membrane were negative. The presence of bacilli in the nasal discharge was observed for from five to thirty-five days. These facts, says the writer, lead to the following practical conclusions: 1. In a number of cases the metadiphtheritic contagiousness ceases with the disappearance of Lœffler's bacillus. Nevertheless, the irritated condition of the bucco-pharyngeal mucous membrane, under the influence of the intercurrent measles, favors the increase of the bacilli and their presence in the mouth; hence the necessity of a bacteriological examination of the products taken from the mucous membrane of this cavity. 2. Not infrequently (in eleven cases out of sixty) Lœffler's bacillus disappears from the throat, but is still found in the nasal discharge. The trouble is thought to be common coryza, which is a mistake, as this discharge is not accompanied with any symptoms of classic coryza. There is no conjunctival injection, or headache, or watering of the eyes. Ordinarily it is unilateral. The discharge is a transparmucus and by no means the sanious discharge which succeeds false membranes of the throat. 3. According to M. Tézenas, Lœffler's bacillus exists in the nasal cavities as long as the nasal discharge continues, and disappears when it does. He adds that when this discharge is absent there are no bacilli in the nose.

In practice, then, says the writer, this fact must be taken into consideration, that a nasal discharge the origin of which does not coincide with the disappearance of the false membranes is not diphtheritic. It does not contain Lœffler's bacillus. The bacteriological examination proves that unquestionably.

Anti-Toxic Action of the Liver.

It has been established for some time, says the *London Lancet*, that the liver has a power of retaining certain poisonous alkaloids in high proportion and in their most active state, when injected into circulation. Dr. Schupfer, of the University of Rome, Italy, has now shown by experiments on frogs that intrinsic action, due to the specific activity of its cellules, the organ diminishes the toxic power of the alkaloids with which it is brought in contact, not only those introduced from without, but those elaborated within the body, as from disease.

CURRENT LITERATURE REVIEWED.

IN CHARGE OF ELLISON J. MORRIS, M.D., AND SAMUEL M. WILSON, M.D.

THE ANNALS OF GYNECOLOGY AND PÆDIATRY, JANUARY, 1895.

Charles Greene Cumston, B.M.S., M.D., Instructor of Clinical Gynecology, Tuft's College, contributes an article on

Parietal Fibro-Myomata of the Uterus, and Professor Vulliet's Operation for their Extraction.

After discussing the general subject of fibroids, the writer proceeds to describe Professor Vulliet's operation for their extraction. The procedure is composed of three steps: (1) dilation; (2) "debridement" of the neoplasm; (3) after treatment.

To make the diagnosis the uretus must be dilated sufficiently to allow the finger to penetrate easily into the cavity. If the cavity be not lengthened, the index finger will be sufficient, but with a lengthened cavity the index and medius fingers must be introduced, and if the fibroid is very high up in a deep cavity it will be necessary to introduce the hand as far as the root of the thumb. Vulliet uses in certain cases male urethral sounds of laminaris, cut the length of the cavity, several being inserted together. When sponge is to be used it should be selected for the size of the cavity to be dilated and should be most carefully prepared. The sponge is cut like a cone. Operation should never be performed immediately after removal of the cones; the cavity is irrigated and packed with cotton, which is left in place for two days; after this the field of operation is considered sufficiently sterile.

Debridement. The incision ought not to be either a simple scarification or a "boutonniere." To accomplish the end the direction and length should be proportional to the direction and length of the greatest diameter of the neoplasm, and its depth should be that of the tissues covering the tumor.

After treatment. On the next day ergotin is given and electricity is applied. The cotton packing is removed every forty eight hours. Neither finger nor foreign body excepting the cotton or the irrigator should be introduced into the uterine cavity. Three eventualities can happen after incision: First, enucleation is immediately done; secondly, the endometrium unites and the tumor slowly developes into a polypus protruding into the uterine cavity; and lastly, no modification may take place, the neoplasm remaining in the same position.

Contra-indication. This procedure is absolutely contra-indicated in all cases in which the dimensions of the growth are such that an incision the entire length of the uterine cavity is not large enough to allow the production of spontaneous enucleation. Also, even when the uterine cavity is large enough to permit of a sufficiently long incision, the upper limits of the tumor are too high up in the abdomen, thus preventing forced enucleation in case commencing infection might appear. And lastly, any symptoms indicating a virulent process in the uterine cavity is an absolute contra-indication.

James A. C Goggans, M.D., of Alexander City, Ala., contributes an original article on

Extra-Uterine Pregnancy.

The author is strongly opposed to the use of morphia or electricity for destroying the life of the fœtus. He says, "I regard those measures as unsurgical and fraught with much danger. Only eight or ten cases of extra-uterine pregnancy have been carried to full term with satisfactory results to both the mother and child, so the chances for such a happy result are so slender that I advise such patients to have the whole mass removed just as soon as the diagnosis is made certain. Especially is this treatment indicated during the first three months and if the rupture has already taken place.

After the fourth month, and up to the period of false labor, operation is not advisable. Operate in all cases after false labor and death of the child, when the amniotic fluid has been absorbed, indicating that the circulation in the placenta has ceased.

Under any circumstances, I would advise operation when the life of the mother is in danger."

Philander A. Harris, M.D., Patterson, N.J., contributes a paper on "Pelvimeters and the Practice of Pelvimetry as a means of Discovering Irregularities of the Pelvis which are likely to Embarrass Parturition," making an earnest and forcible plea for the more general use of pelvimetry. The various forms of the instrument are described and illustrated and their imperfections shown.

A. Lapthorn Smith, M.D., etc., of Montreal, Canada, contributes an article entitled "What has Sewer Gas got to do with Bad Results in Obstetrics and Gynecology," relating a number of instances in which patients did badly on account of poisoning of the atmosphere by this gas

Carey Kennedy Fleming, M.D., describes "An Aseptic Goodell Dilator" designed by him.

The editorials in this issue are: "Holmes and Puerperal Fever," "Professor Richelot and Vaginal Hysterectomy," "The Special Action of Permanganate of Potassium on the Gonococcus."

In the Department of Pædiatry, E. Channinm Stowell, M.D., of Boston, describes "A Cheap Form of Malt Diastase for Poor Practice."

The editorials in this department are: "Dr. Hartwell and the Condition of Health in Massachusetts," "Foreign Bodies in the Heart," "The Relation between Tuberculosis and Diphtheria."

[In reviewing the paper of Dr. Geo. S. Peck on Appendicitis, which appeared in the last issue of the *Annals of Gynecology and Pædiatry*, the statement was made that the author had lost two cases out of the four reported. The author has called the attention of the editor to the fact that there was but one death out of four—the second death occurring in a fifth case, reported for comparison. The editor takes great pleasure in correcting this mistake on his part. In a personal letter Dr. Peck states that he has made seventeen operations for appendicitis (all pus cases but one). Thirteen out of the seventeen are alive and perfectly well.—E. J. M.]

THE BRITISH JOURNAL OF DERMATOLOGY FOR FEBRUARY.

Dr. Alfred Sangster reports a case of

Congenital Exfoliation of the Skin.

The patient was a man of twenty-four years who seemed rather stupid. The history given by his parents was as follows: The parents were both healthy and had ten children, four of them living and healthy. No history of syphilis nor any affection similar to this one.

Three weeks after the birth of the patient the skin of his forehead began showing signs of desquamation and in three years this had spread over the body. The patient is physically weak but seems to have good health excepting loss of sleep from the itching due to this skin affection. Three or four times yearly there are exacerbations and at these times the scales are cast off so freely that handfuls may be collected from his bed. He suffers also from chronic constipation.

Removing the clothing the patient was found to be fairly well nourished, seemingly not very muscular. The skin was dusky, deepening to brownish in places, and the general complexion dark.

Extensive areas of brittle crackling epidermis similar to those surrounding old leg ulcers could be found and from those sheets of epidermis might be peeled, the surface underneath appearing grayish, sticky and smooth. No inconvenience resulted immediately; but in a short time a tingling or smarting would be felt and the denuded surface would become marked by hyperæmic, and then subside by degrees to the condition of that removed. Examination of the removed superficial layer showed the under surface marked by a network similar to that of normal skin and without the papillary elongations found in ichthyosis. Other areas were found with these changes going on spontaneously. The nails and hair seemed unaltered.

The case is considered unique and to differ from ichthyosis in the absence of hyperkeratosis and of papillary hypertrophy.

Dr. Henry W. Stelwagon has an article on "The Contagiousness of Molluscum Contagiousum," quoting most of the cases on record bearing on the subject and stating that at intervals the controversy is renewed and always closes with some more evidence in favor of the infection theory. He is decidedly of the opinion that the disease is communicable.

JOURNAL OF NERVOUS AND MENTAL DISEASE

Dr. Philip Meirowitz reports a

Case of Multiple Neuritis Due to Acute Arsenic Poisoning.

The patient was a young man of nineteen years, who swallowed a teaspoonful of arsenious acid in mistake for bromo seltzer. As soon as he discovered his mistake he vomited as much as possible of the poison and went home and to bed. Three hours afterward severe vomiting began and the iron antidote prescribed by a physician was rejected as well as everything else.

After an illness lasting eleven days, and during part of which the patient had hemorrhages from the ears, hallucinations of sight, delirium, etc., convalescence began. Nine days after this severe burning pains began in the legs, preventing sleep, and three days later they extended to the feet and these became swollen. These pains continued for nine weeks. There was at no time any pain in the arms, but some tingling in the hands.

The patient came to the dispensary on crutches. He had no facial paralysis, no speech disturbance, and had had no double vision. Examination shows his gait to be markedly ataxic, walking performed better with the shoes on than off, and marked involuntary twitchings in the calf muscles. There is marked tenderness to pressure along the feet, legs and thighs, and the muscles of the leg are atrophied. Coarse strength is preserved in the thigh muscles. The foot, patellar and cremasteric reflexes are gone; but the gluteal, abdominal and epigastric ones are present.

Tactile anesthesia is found in the feet and to a point just above the ankle joint; above this is an area of hyperesthesia and there is general hyperesthesia to pain throughout the lower extremities. The feet are anesthetic to the thermal test and the lower legs hyperesthetic. Anesthesia to galvanic and faradic currents is found in the legs. The muscles of the hand are atrophied, those of the body not affected, and no disturbances referable to the central nervous system.

The treatment consists in the use of the static and the induced currents, and the internal use of strychnine sulphate, of which one-twelfth of a grain is being given three times daily, with apparent benefit.

THE PHYSICIAN AND SURGEON.

Dr. W. H. Haughey writes of the

Treatment of Eclampsia.

The opinion of the author is that this disease is a taxæmia in which the renal disturbance is at most an accessory, and is probably very frequently a result, as in diphtheria. Cases are frequently seen in which there is decided albuminuria, but no uræmic symptoms, and cases in which no urinary trouble

was found until just before the eclampsia showed itself. A theory that he is disposed to accept is that there is a poisoning by fœtal waste products. Whatever the cause may be, the best treatment for a patient who threatens to have the disease, is the prophylactic one—stimulation of the skin, kidneys and bowels When the convulsions begin the author has used with success a quarter grain of morphine after each spasm unless, he says, they are too close together. From ten to twenty grains of calomel are given in divided doses, and, in one or two cases, an eighth of a grain of elaterium was given every two hours until one-half grain was given.

Other writers have advocated rectal injections of chloral, every half or three-quarters of an hour if required, no less than one half drachm being given at a dose, tincture of veratrum viride in fifteen minims to one drachm doses every fifteen minutes until the full physiological effect (vasomotor paralysis) is obtained, etc., and good results seem to follow each of these methods. Chloroform will control the convulsions, but seems an undesirable substance to use on account of resembling in its effects the narcosis following the convulsions. Blood-letting has long been recognized as one of the best means of treat ing a plethoric patient, and the majority of cases of eclampsia occur in such women.

Dr. F. Maas reports the

Cure of an Hepatic Abscess of Long Standing by Operation.

In northern climates the author thinks hepatic abscesses a comparative rarity and that the majority of pus accumulations in this region occur around rather than in that organ. While an abscess may occur in the liver from the entrance of pus from various sources, the most common is probably that following tropical dysentery.

The subject of this history is a man forty years of age who suffered seventeen years ago from recurrent jaundice without pain. During the last six or seven years this became persistent and during the summer would be accompanied by pain in the hepatic region radiating to the shoulder and back. These symptoms disappeared at the approach of cold weather, but last winter they continued and the pain become so severe as to interfere with sleep. The bowels were alternately constipated and quite loose. There is no history of previous bowel trouble excepting an occasional diarrhœa due to beer. Severe chills were felt at intervals last winter.

Physical examination showed the temperature to be 103°, the tongue coated, skin tinged grayish yellow, the upper border of the liver at the usual level and the lower one two or three inches below the boundary of the ribs, the spleen was a little enlarged, the liver region sensitive to touch, the urine normal, and the gall-bladder difficult to outline but seemingly enlarged.

Under chloroform an incision seven inches long was made over the lower border of the liver. Palpation revealing a hard spot on the convex surface of the liver, one of the ribs was resected, an opening made in the pleura and the diaphragm and the edges of the latter stitched to the skin incision The wound was packed with gauze, and the formation of adhesions waited for.

Three days later, after considerable pain and rise of temperature, a free movement of the bowels took place and gave great relief and resulted in an almost normal temperature. The discharge contained much pus.

The following day under chloroform anesthesia three large trocars were inserted into the abscess and about a pint of thick odorless pus withdrawn; the canulas left in position, to avoid hemorrhage, and the wound dressed.

A free discharge of pus continued, as much as one pint to one-half pint escaping daily for three weeks.

The patient developed a good appetite and made so good a recovery that there is now only a small discharging sinus and the author is not disposed to take much pains to have this heal as he thinks it a safeguard against another accumulation of pus. In his opinion this trouble started seventeen years before with the absorption of a little pus from an intestinal ulcer, and the abscess emptied itself pretty thoroughly for eleven years, and then at intervals for six more; but then in some way the escape of pus was partly prevented and the symptoms became prominent. Streptococci and staphylococci were found in the pus, but no amœbæ coli.

Dr. Harvey J. Chadwick makes a plea "Pneumotomy in Phthisis Pulmonalis." English surgeons in Australia employ this treatment with success, and it is certainly in accord with modern surgery of other parts of the body.

According to the experience of Adjunct Prof. Vansant, *recurring habitual* or *epistaxis* is due, in the large majority of cases, to ulceration of the anterior and inferior portion of the nasal septum, and is associated with slight or moderate deformities of the septum. The following treatment is recommended:

Treatment of an attack, which may be carried out by the patient, consists of firm and prolonged compression of the nose with the fingers, the patient being seated or reclining, and the head held erect, or bent slightly forward; if this is not successful, a loose plug of absorbent cotton saturated with full strength official solution of hydrogen dioxid is inserted and the compression of the nose continued. If the patient finds it necessary to seek professional aid, the bleeding point should be found and touched with pledgets of cotton saturated with a 5 per cent. or 10 per cent. solution of silver nitrate; if this is unsuccessful, the galvano-cautery knife heated to a dull red, should be lightly applied to the source of hemorrrhage. The patient should be instructed to apply emollient ointments, and to avoid picking the nose.

For the permanent relief of such cases, it is desirable to correct the existing deformity of the septum, otherwise repeated ulceration is likely to occur from slight abrasions due to accumulation of dust and scabs. The desire to pick the nose, under such conditions, is almost irresistible. Correction of the septal deformity prevents these accumulations and the temptation to pick the nose is removed.

PERISCOPE.

MEDICINE

Lumbar Puncture for the Removal of Cerebro-Spinal Fluid.

This was the title of a paper by Dr. William Browning, of Brooklyn, read at a meeting of the American Neurological Association. He reviewed the main points in this recently devised operation. Brief notes of a few cases were given, as well as directions for its performance. The following conclusions were reached:

1. The method was simple, easily practised and rather attractive.
2. In itself it was usually without danger.
3. By it we certainly could draw off cerebro-spinal fluid.
4. The quantity removed at short sittings had been from one ounce to one and a half in adults.
5. This without doubt represented the amount of free fluid usually present in the lower vertebral canal even when occluded above.
6. In internal hydrocephalus the relief, if any, was but very temporary. In the common form due to tubercular meningitis the result was not worth the trouble, while in the closed or sacculated forms it must rather do harm than good.
7. As a diagnostic means—*e.g.*, in suspected meningeal hemorrhage—it was valuable. As an index of pressure it might also be worth noting.
8. It was worth further trial—(*a*) as a passing relief in brain tumors not complicated by hydrocephalus; (*b*) as a substitute for trephining in progressive dementia; (*c*) in certain spinal troubles; (*d*) and possibly as a means of applying medication directly to the spinal meninges.
9. In conclusion it might be said that, while admissible in all cases of brain pressure, there is as yet no established indication for this procedure except for diagnostic purposes.

Ingrowing Nail.

At a recent meeting of the Congres de l'Association francaise pour l'avancement des sciences, a report of which is published in the *Progres Medicale* for September 1st, M. Felix Regnaut, of Paris, read a paper on this subject. He remarked that different writers had attributed this trouble to many causes—such as lymphatism, improper shoes, etc.—without defining the relative importance of each. Some writers had regarded shoes as the principle influence in causing ingrowing nails, although Dionis had observed ingrowing nails among bare-footed monks, and Binaud had seen it among tuberculous patients who were confined to their beds. Tight shoes had deviated the great toe and bent the nail, but not sufficiently to cause ingrowing, and although it might be curved like a claw and sunk deeply into the flesh, it did not necessarily give rise to ulceration. Poniet had shown that lymphatic persons who had small, flat nails and a thick great toe were often subject to ingrowing nails. The constitutional condition was the primary cause; shoes played only a secondary part and applied only to one class of ingrowing nails, which occurred in healthy, non-strumous persons, the great toe of whom had been more or less altered by the kind of shoes worn.

M. Regnault thought that traumatism and dirt were predominant factors in giving rise to cultures of common microbes in the pus in the groove of the nails. Sometimes, also, a contusion of the great toe had caused ingrowing nail. Traumatism might occur after cutting the nails. The speaker had observed two cases, one where the nail had been improperly cut, and the skin broken; several days afterwards the nail had begun to grow in. In the other case, that of a young man who had his nails attended to in a bathing establishment, suppuration had set in eight hours afterward. This pathogenic knowledge, said the speaker, had an important bearing in relation to the treatment; if ingrowing nails were properly cared for at the beginning, they were easily cured by constant bathing in carbolized water and by antiseptic dressings.—*N. Y. Med. Jour.*

The Tendon-Achillis Phenomenon.

Ziehen (*Deut. med. Woch.*) concludes a discussion on this subject based on a large number of cases. He has found that out of one hundred and eighty-eight general paralytics this tendon-Achillis, or ankle jerk, was normal only in fifty-seven. An inequality between two sides was very common. The gradual diminution and disappearance was actually observed. Sometimes the loss of this tendon reflex was an early symptom. The knee-jerk is not always absent at the same time Thus in twenty three cases the knee-jerk was present, and yet the ankle-jerk was lost on one or both sides. The loss of the ankle jerk is very uncommon in functional psychoses or neurasthenia, and the author does not believe that it is often absent in health. Once the jerk unquestionably reappeared under vigorous mercurial inunction. Foot-clonus is very common in general paralysis, but is of no diagnostic significance. A one-sided or double-sided weakening of the ankle-jerk is strongly in favor of general paralysis as against functional psychoses. It will not serve to distinguish general paralysis from senile dementia, cerebral syphilis, or chronic alcoholism. In senile dementia it was altered in thirty cases. In secondary or

congenital imbecility it may point to congenital syphilis as a cause. Foot clonus and unequal ankle-jerks are more common in hysteria than in epilepsy, the increase being on the side of the hemi anesthesia. In chronic alcoholism diminished or absent ankel-jerk was commoner than foot-clonus. Absent ankle jerk on one or both sides is very uncommon in functional psychoses or neurasthesia, being present without doubt only in four cases. The author concludes that the ankle-jerk is quite as important as the knee-jerk, that absolute indications are as rarely given by it as by the knee-jerk, that absence on one or both sides is of the greatest importance, and that the loss of it in a mental case points with great probability to general paralysis or syphilis of the central nervous system, or in a less degree to senile dementia or alcoholism. Peripheral complications, such as sciatica, etc., must be excluded.—*British Med. Journal.*

Antipyrine in Laryngology and Rhinology.

Antipyrine has been used almost since its first introduction to the profession as a hemostatic in epistaxis, with marked success, a four per cent. solution being thrown into the nostrils as a spray, or applied upon a pledget of absorbent cotton. Now, the solution is used either as a spray or as a direct application upon any oozing surface. It is unirritating, and unlike those preparations which check the flow of blood by the formation of a clot, it constricts the blood vessels, so that the surface seems blanched, as if all the blood were pressed out. In tonsilitis and pharyngitis, when the pain shoots up into the ears and effects the swallowing, the spray checks the spasm, relieves the pain, and reduces the active congestion.—*N. Y. Medical Times.*

Report of a Case of Acute Supra-Glotic Œdemia Without Apparent Cause.

Dr. John Pryor (*Medical Record*), the patient, a dentist, aged thirty, vigorous and healthy, consulted the author on account of difficulty of speaking and breathing. The trouble came on suddenly in the early hours of the morning, the patient waking up with a slight sense of fulness and discomfort in the region of the throat. Towards the afternoon of the same day the condition became worse; the face wore an anxious expression, and the voice had a peculiar metallic resonance. On examination the epiglotis and ary-epiglotic folds were seen to be very œdematous. The former showed a line of division in the center, which gave the appearance of two large puff-balls. At its base or lingual surface of the right side a large bleb of about one-fourth of an inch in diameter was seen. No view of the interior of the larynx could be obtained. There was also pronounced infiltration of the connective tissues of the neck in the region of the larynx. No pain was complained of. Respirations were eighteen per minute; pulse and temperature normal. Six leeches were applied to the laryngeal region, a hot mustard foot-bath, wrapping in blankets, and copious draughts of hot lemonade and whisky being also ordered. Relief soon followed. The author states that no evidences of cardiac or of renal disease could be found. The following considerations he points out as worthy of careful study: 1. The absence of any known causative agency and constitutional symptoms; 2, the extent of œdema which may occur without marked dyspnœa; 3, the peculiar character of the voice; 4, the marked benefit of prompt treatment without scarification; 5, the possibility of the case belonging to a group of obscure clinical manifestations known as anglo-neurotic œdema or allied vaso-motor curiosities.—*Journal of Laryngology, Rhinolooy and Otology.*

Inflammation of the Middle Ear of Infants.

Dr. A. Hartman (*Deutsche Med. Wochenschrift*) gives the results of investigations of this subject in the Institute for Infectious Diseases, Berlin:

1. Post-mortem examinations and examinations of the ears of living children establish the fact that 75 per cent. suffer from inflammation of the middle ear.
2. Inflammation of the middle ear can nearly always be determined by an otoscopic examination.
3. The symptoms of the otitis media consist of restlessness, elevation of temperature and loss of weight. Sometimes these symptoms are not present.
4. Very often the symptoms of otitis media are connected with broncho-pneumonic processes. Probably both processes are due to the same process, viz., aspiration.
5. Death can result in cases of otitis media, slow stone atrophy, or from an extension of the micro-organisms into the cranial cavity, (meningitis) or into the blood (septicemia).
6. The inflammation of the middle ears of infants must receive treatment suitable for the varying conditions.—*American Journal of Medical Sciences.*

Diphtheria.

Dr. L. Emmett Holt summarizes the treatment as follows:

1. Germicidal treatment, preferable by the use of strong hydrochloric acid, used early to be effectual; especially valuable in cases beginning on the tonsils.
2. Local cleanliness by the use of a weak antiseptic solution in the pharynx.
3. Nasal spraying with the same solution in every case where there is nasal discharge.
4. Alcoholic stimulants begun as soon as the first systemic effects of the poison are seen, and in very severe cases pushed to the point of tolerance.
5. Calomel fumigations as soon as laryngeal symptoms appear.
6. Intubation in laryngeal cases not relieved by fumigations.

Heart Disease and Menstruation.

Dr. Gow recently read a paper (*Lancet*) before the Obstetrical Society of London, with a record of 50 cases. In 28 the flow was unaltered; in 17 the flow was absent or scantier than before; in 5 the flow was either more profuse or recurred more frequently than before; in no case was there good evidence that heart disease gave rise to severe menorrhagia. It would seem that either amenorrhœa or scanty menstruation was a far more common accompaniment of heart disease than menorrhagia. A further analysis of these cases seemed to point to the fact that heart disease led to relative sterility, and also that it greatly increased the tendency to premature expulsion of the ovum. In conclusion, it was pointed out that a large number of women suffering from valvular disease of the heart pass safely through the period of pregnancy and labor. The cases were further analyzed as follows:

1. Mitral stenosis (22 cases): In 9 cases menstruation was regular and the amount lost unaltered, in 5 cases menstruation was regular but more scanty, in 4 cases there was amenorrhœa, and in 4 cases menstruation was either more frequent or more profuse.

2. Mitral incompetence (15 cases): In 10 cases menstruation was unaltered, in 4 cases menstruation was more scanty, and in 1 case there was amenorrhœa.

3. Mitral stenosis and incompetence (7 cases): In 4 cases menstruation was unaltered, in 1 case menstruation was more scanty, in 1 case there was amenorrhœ, and in 1 case there was slightly increased menstrual loss.

4. Aortic incompetence and obstruction (2 cases): In both cases menstruation was unaltered.

5. Aortic and mitral incompetence (3 cases): In all cases menstruation was unaltered.

6. Aortic incompetence and obstruction and mitral incompetence (1 case): Menstrual loss was more scanty than before.—*The Kansas Medical Journal.*

The Pathology of Enlargement of the Prostate.

(*Lancet.*) By C. Mansell Moullin, M.D., of London.

The theories current at present regarding this condition are: 1. That based upon the analogy between it and fibroid disease of the uterus. 2. That it is merely an occurrence in a constitutional disorder which begins as an arterio-sclerosis and ends in fibroid degeneration, affecting the genito-urinary organs in a special manner. 3. That it is secondary to and developed as a compensatory measure to primary changes in the bladder.

These three theories are disproved by the following facts: 1. The prostate is not homologue of the uterus. 2. Uterine growths originate as fibromyomata and have little or nothing to do with the mucous membrane; neither does the enlargement begin as a fibroid degeneration, but as a glandular overgrowth. 3. The prostate is of sexual origin and has to deal only with sexual function. It has nothing to do with micturition, which, if the prostate remains undeveloped or undergoes atrophy, takes place just as if the prostate were normal. There are, however, certain facts which we know that suggest the real cause. The enlargement is dependent in some way upon the testes. The evidence in favor of this is in brief as follows: 1. The normal development of the prostate is undoubtedly controlled by that of the testes. Up to puberty there is no prostate worth mentioning. 2. If castration is performed before puberty the prostate never grows; if after puberty, it wastes and disappears, and the same has now been shown to be true of the abnormal development known as enlargement. This rarely begins after an age at which it may be presumed that the testes are no longer functional, and it disappears if they are removed. There are now nine cases on record in which castration has been followed by a complete disappearance of the enlargement within a few weeks. How the testes act is questionable. The mere induction of sterility (such as by section of the vas deferns,) although it may cause atrophy of the tests, does not appear to be sufficient. The influence, whatever it is, comes from the testes themselves and exists so long as they are present. It may be exerted through the nervous system or through the circulation. Three cases have lately been reported of unilateral atrophy after removal of one testicle. If post-mortem examination of these cases should show this to be true, it is probable that the influence is exerted through the nervous system.

If this suggestion, that enlargement of the prostate is dependent upon some change which takes place in the testes during the latter part of their active life, should be accepted, it will be a curious instance of the way in which modern views are sometimes foreshadowed by the speculative theories of a long past date.

Why People Become Deaf.

It has taken the medical world a great many years to discover that loss of hearing is almost invariably caused by some disease of the throat or nose or both. But very recent researches in these fields have demonstrated this fact beyond question, and it is now admitted by the more advanced medical men that, aside from rupture of the ear-drum, there is scarcely a symptom of defective hearing which is not traceable directly to the condition of the nose and throat.

In view of the new discoveries, ear specialists are finding their occupation gone, save as they make their particular branch an assistant in further investigation. It is said, as we have already pointed out, that the use of smelling-salts is one of the most prolific causes of deafness, operating by weakening the olfactory nerves, and through them the auditory system. All strong or pungent odors should be avoided as far as possible, especially those which act upon the secretory processes, and, as the popular expression goes "make the nose run."—*Medical Brief.*

Heart Surgery Next?

A contributor to the Medical News suggests that the principles upon which wounds in other vital organs are dealt with by modern surgery might often be applied with equal success to the heart. In view of cases on record in which the heart has resisted the effect of gunshot and other wounds for hours and even days, it is at least open to discussion whether a surgeon might not open the pericardium, clean out the clots, and close the wounds in the heart wall, with a chance for the patient of recovery which certainly could not be lessened by the attempt. It is claimed that this is no more improbable now than the safe removal of a tumor from the motor area of the brain seemed to be in the recent past. That the application of sutures would necessarily stop the action of the heart, is not proved; and if it should be, there would remain a question of possibly starting it again. The danger from the entrance of air into the circulation has been proved not so great as has been supposed. Drs. Hare and De Schweinitz, of Philadelphia, who have done much work along the line of experimental cardiac surgery, have demonstrated that the intravenous injection of large quantities of air is not necessarily fatal.

Ureterotomy.

In the December number of the *Bulletin* of Johns Hopkins Hospital, Dr. Howard Kelly gives some interesting details of three cases of ureterotomy undertaken for diagnostic purposes. Whilst operating for severe pelvic diseases, he noticed in three of his cases such bulging of the uterus as led him to the belief that one of the uterus had been included in some of the ligatures which had been placed to control bleeding. After locating the ureter over the brim of the pelvis, he cut a slit in it, and passed a catheter through the ureter down into the bladdder in two of the cases, thereby demonstrating that the ureter was previous, and concluding that the dilatation was probably due to pressure upon the ureter by the tumor which he had just removed. In one of the cases he found, as he suspected, that one of the ureters was included in a ligature. This he cut, after which he could pass the catheter freely into the bladder. The slit in the ureter he repaired by mattress sutures. In one of the cases there was leakage of urine, which, however, was controlled by superficial sutures. Care has to be taken not to make the sutures pass into the lumen of the ureter. In these cases the operation on the ureter had no untoward effect upon the patients, recovery having been uninterupted in each case.

Blood-Letting in Over-Distention of the Right Heart.

Dr. I. E. Atkinson, of Baltimore (Maryland *Medical Journal*), thinks that blood letting, in this condition, is of the highest, at times, of life-saving usefulness. Mechanical relief is afforded by the abstraction of blood in cases where the right side of the heart becomes engorged or over-distended, in consequence of increased obstruction to the flow of blood through the lungs, or left side of the heart, as may be seen in severe bronchitis, emphysema, pulmonary œdema, incompetency of the mitral valves, or stenosis of the mitral orifice. In some cases where there has been mitral disease, and the hypetrophy is followed by dilatation and degeneration, the heart may be too much diseased to avail itself of the relief coming from venesection. In cases where the right ventricle becomes suddenly distended beyond the power of its systole, in acute bronchitis is an emphysematous lung, marked benefit comes from blood-letting. The feeble action of the right ventricle is rapidly relieved by this means. The balance of the circulation is greatly improved. The veins are emptied, and more blood flows into the arterial system. The systole of the right ventricle again becomes efficient, and the cyanosis disappears. In advanced cases of mitral disease the benefits are often temporary. In pulmonary œdema and engorgement very brilliant results may be obtained. As the blood flows from the arm the patient feels marked relief. The dyspnœa subsides; the cyanosis lessens; the pulse grows slow and fuller. The patient usually falls into a quiet sleep. From one to two pints may be taken with safety. The author mentions a case where the patient had ceased breathing. He resorted to artificial respiration and venesection. When half a pint had escaped respiration began. The patient made a good rocovery.

Treatment of Typhoid Fever.

Dr. Osler, of Baltimore, in discussing the treatment of typhiod fever at a recent meeting of the Clinical Society of Maryland, said: He thought that the antipyretic drugs were entirely superfluous in this disease. The cold bath is more efficacious, but is not always available in private practice; but all the good effects of the bath can be obtained by sponging. A good nurse or doctor can sponge the patient so effectually that the fever will be satisfactorily reduced. When the temperature is high, ice sponging—not with ice water, but with lumps of ice—over the back and legs will reduce the temperature very pleasantly to the patient, and satisfactorily to the doctor. Delirium and stupor are also effectively treated by ice sponging. The use of modern antipyretics in typhoid fever is, in nine cases out of ten, positively hurtful. They reduce the heart's action, and cause weakening sweats, and their use is an unmitigated evil. In the majority of cases the treatment may be taken from old Dr. Nathan Smith, of Yale, which was pretty much that of to-day: Plenty of fresh air, liquid diet, and cold externally. He was in the habit of turning out the friends of the patient, putting the patient on the floor, and then dashing water, handed through the window by an assistant, over the patient.—*Canadian Practitioner.*

The Hygiene of the Kidney.

Dr. J. Henry C. Simes, of Philadelphia (*Diet. and Hyg. Gazette*) deals with the care of the kidneys. He calls attention to the relation between the skin and the kidneys, and observes if the skin is not in a healthy condition the kidneys have an extra volume of work to perform. The importance of a healthy action of the kidneys is manifested by the fact that serious trouble may arise in other organs, as heart, lungs, brain and nervous system, when the excretory work of the kidneys is imperfectly done. In watching the action of these organs many factors must be taken into consideration, such as the nature of the diet, the amount of liquids consumed, the nature of the exercise and activity of perspiration. Then again, as the urine varies so much, a correct examination cannot be made unless the entire amount voided in twenty-four hours be collected, and a specimen taken from this. The quantity of urine varies greatly with the amount of liquids holding the solid constituents of the food in solution. When it is remembered that nine hundred and fifty parts of every thousand of the urine are water, the importance of this element in the dietary becomes evident. On this point, the author is strongly of the opinion that the majority of men eat too well and do not drink enough water. As a result of this, there is deposited in the tissues many effete products that should be carried off by the kidneys. The work done by those organs is in this way interfered with; and in time organic disease often come on. It is owing to the large amount of water that much of the benefit from a milk diet arises. In advocating the use of abundance of water with the solids, the author again calls attention to the danger of washing down the food with it, and taking time to masticate properly. While water is of prime importance, it cannot take the place of the saliva. The benefit derived from a sojourn at a mineral spring is almost entirely due to the flushing out the system gets. Waste products are dissolved and washed away by the kidneys. The opinion is expressed that pure water drank for a lengthy period would have as good an effect. This of course applies to cases where there is no organic lesion, and efforts are directed against the ill-effects of a sedentary life and over-eating. In advocating the use of water, its excessive use must be guarded against. The habit of taking too much water may be indulged in. This is the other extreme, and may result in harm. The effect of water is to make the kidneys act, and by over drinking these organs may be over worked. The abuse, therefore, of water may prove the reverse of "in aqua sanitas." In the cold season, warm clothing is of much value, as tending to prevent congestion of the kidneys. Should such happen, it must be relieved by acting upon the skin and bowels. Judicious bathing is useful, as tending to maintain the healthy action of the skin, and thereby avoid congestion of the kidneys. If many people drank more water, and used less solid food, kidney diseases would not be so common as they are at present.

Guaiacol in the Treatment of Gonorrhœal Epididymitis.

At a recent meeting of the Societe Medicale des Hopitaux of Paris (*Union Med.*), M. Balzar and M. Lacour stated that they had obtained excellent results in the treatment of gonorrhœal epididymitis with guaiacol. On the skin of the inguinal region, they said, pure guaiacol could be applied; on the scrotum it was better to employ an ointment of from two to five parts of guaiacol to thirty of vaseline. One of the first effects of the application of this ointment was a rather sharp burning, lasting for about ten minutes; then the patient felt a sensation of heat, and almost immediately the pain disappeared, at least for three or four hours, and sometimes it did not return Ordinarily it was necessary to make two applications on the first day, but after the third day there was no longer any pain. The applications were then discontinued, for they did not seem to exert any very decided resolvent action upon the inflammatory infiltration of the epididymitis. It was evident, the authors said, that guaiacol exerted a very clear and energetic effect upon the pain of the disease; moreover it overcame certain of the general symptoms which were due to the pain, for example, sleeplessness. It gave rise to a slight erythema of the scrotum, followed by drying and exfoliation of the epidermis. The authors had treated twenty cases with guaiacol, and in all of them the results had been most favorable and very rapid.

A New Method of Shortening the Tendo Achillis.

Phocas (*Am. Med. Surg. Bulletin*) proposes the following operation:

A median incision five or six centimeters is made over the tendon, the sheath opened and the tendon carefully denuded. It is then transfixed laterally at the upper end of the wound by a bistoury which is carried down the middle of the tendon by a sawing motion. The posterior flap is cut away above and folded on itself, and this is now done, the freshened surfaces together, thus shortening it one-half the length of the incision, and the fold stitched together with catgut. The sheath is closed, and the skin also separately. The foot is then put up in equinus in a fixed dressing.

Treatment of Collapse from Loss of Blood.

In a paper printed in the Texas *Medical Journal*, Dr. A. S. Fuller, of Houston, cites two cases of collapse, due to *post-partum* hemorrhage, treated by the injection of a salt solution into the peritoneal cavity. The first case was a multipara about thirty years of age, the hemorrhage coming on a few moments after expulsion of the placenta, and collapse occurred before the flow could be checked. Stimulants, hypodermically position, and heat failing to have any effect, one and one-half, pints of a hot two per cent. solution of sodium chloride was injected into the peritoneal cavity, and in about three hours the patient was sufficiently recovered to allow the doctor to leave.

ORIGINAL ARTICLES.

ETIOLOGY AND PROPHYLAXIS OF PULMONARY TUBERCULOSIS.*

HENRY LANDIS, M.D., READING, PA.

The question of contagion in tuberculosis appears to be still in controversy. The older writers were almost universally opposed to the theory of contagion, and the great Louis, who wrote some fifty years ago, and to whom is due the credit of having made a more careful and elaborate investigation into all questions relating to pulmonary consumption than any other man of the age in which he lived, does not even mention contagion as a cause of the disease. Dr. Thomas Watson, another eminent authority, in reply to his own question, "Is consumption contagious?" says, "No, I really believe it is not. * * * The disorder, I am satisfied, does not spread by contagion." Prof. George B. Wood, in his excellent work on the Practice of Medicine, published some thirty-five years ago, says, "Phthisis is pre-eminently a hereditary disease," and he was in the habit of advising his pupils, before pronouncing a diagnosis in any case of lung disease, to trace back the pedigree of the patient to at least the grandparents, before abandoning the search for some hereditary predisposition of phthisis. He does not allude to contagion, or any specific agency as a possible cause of consumption. Dr. Austin Flint ignores contagion, and leans so strongly to the theory of heredity that he says, "It may reasonably be conjectured that a predisposition may be inherent in the organism of persons none of whose relatives have had phthisis. Indeed, it may be that the diathesis always involves a congenital predisposition, that is, it is never wholly acquired." Dr. Cotton, of the Brompton Hospital for Consumptives, and Dr. McCormac, of Dublin, are strongly opposed to the theory of contagion, and the former goes so far as to say that "a residence in the consumptive hospital (Brompton), and a long continued working in its wards, is a good way, indeed, not to catch the disease." This declaration he bases upon statistics collected at his hospital during a period of twenty-one years, showing an exceedingly small percentage of mortality from consumption among the internes of that institution. The much quoted Dr. Williams apparently straddles the question, and while, in the main, combatting the theory of a specific contagion, admits "that a noxious influence may pass from a patient in advanced consumption, to a healthy person in close communication, and may produce the same disease."

On the other hand, M. Villemin, in 1865, after a series of careful experiments on healthy rabbits, announced that tubercle is a virus, and communicable from one animal to another. His experiments were repeated by Lebert and others with results

*Read before the Lehigh Valley Medical Association, at Easton, January 31, 1895.—From advance sheets of "Lehigh Valley Medical Magazine."

that confirm the opinions of Villemin. Tappiener, of Meran, experimenting on dogs, succeeded in producing tuberculosis of both lungs in ten out of eleven of them; and also of the kidneys in most of them, by causing them to inhale the air of a chamber previously contaminated by spraying, with an atomizer, a mixture of tubercular pus with water. The seances were daily of two hours duration, for an average period of thirty-five days. Every physician, of any considerable experience, must recall numerous instances in which persons in good health, without any hereditary tubercular taint, have died of consumption after intimate and long continued association with one sick of the disease; as in nursing a dear friend.

Notwithstanding the negative testimony of Dr. Cotton, we have, on the contrary, the records of numerous institutions, under the charge of the Catholic Order of Sisters of St. Francis, which show a fearful mortality from consumption among these assiduous and devoted nurses. My personal observations, during a period of twenty-two years' service at St. Joseph's Hospital, Reading, Pa., under the management of said sisters, confirms the reports from other similar charities. This large mortality among these sisters from this cause, cannot be ascribed to heredity, since they are not the descendents of any special class or community of people, but represent various classes and nationalities and, therefore, are presumably fair exponents of the average health of the general population.

Nevertheless, fourteen years after the discovery of Villemin, Dr. Henry Hartshorne, in a note to Reynold's System of Medicine, after reviewing the experiments of Villemin, Lebert, Tappiener and others, and after fully discussing numerous supposed examples of infection, states as one of his conclusions, that "Tubercle is not a specific morbid product, and therefore in no strict sense can phthisis be called a contagious disease." However, in the light of recent bacteriologic research, prosecuted with such earnest zeal in almost every part of the world; of the discovery, by Villemin, of the communicability of tuberculosis from one animal to another; of Koch's find of the bacillus tuberculosis, a microbe constantly present in the disease; and of clinical experience; it is difficult to escape the conviction that tuberculosis belongs to the list of zymotic or contagious diseases, and that the Koch bacillus is the pathogenic agent thereof. I cite the opinions of the older authorities chiefly to show how tenaciously the mind clings to old dogmas based upon antecedent authority, and how difficult it is to root up such dogmas even by an array of stubborn contradictory facts.

But, laying aside the statement of facts and statistics, what conclusions can we come to in regard to the contagiousness of consumption by a process of reasoning? It cannot be denied that the disease is governed by the universal law of cause and effect; being an effect, it must have a cause, and this cause must be either intrinsic—be inherent in the individual, or come from without. Now, if the disease were universally hereditary, as has been contended by Flint, it would be liable to spontaneous extinction, under the two laws of "natural selection" and the "survival of the fittest." Under natural selection because marriageable young people are inclined to shun conjugal relations with those who are afflicted with, or manifestly predisposed to the disease; thus diminishing the opportunities of propagating phthisical offspring. Under the survival of the fittest, because the average age of consumptive women at death is only about thirty years, and from the marriageable age to that of thirty, they cannot bear as many children as healthy women do up to the age of the menopause. And, besides, of the children they do bear some would die of tuberculosis, in addition to the usual mortality from other causes, before arriving at the age of maturity. For these reasons it would follow, as a natural consequence, that the ratio of the consumptive to the healthy population would diminish in each succeeding generation, until the disease would become extinct in the human family in the lapse of ten or twelve generations; this has not been the case.

But the anti-contagionists contend, further, that the predisposition is inherited in only about thirty-three per cent. of all cases, while in the remaining sixty-seven per cent. it is acquired by the operation of such causes as imperfect nutrition, vitiated atmosphere, depressing mental emotions, excessive venery, intemperance, etc., and, in fact, any cause that will lower the vital

energies. But predisposition, whether inherited or acquired, is not a disease; it is simply a condition of diminished resistance in the economy to the aggressive operations of pathogenic agencies. If tuberculosis were an affection developed fortuitously, and not dependent upon any specific extraneous cause, this condition of diminished resistance would be just as likely to develop typhoid fever, diphtheria, or smallpox, as phthisis, because these maladies also thrive best on conditions of lowered vitality. But no one would allege, in this age, that smallpox or scarlatina are of spontaneous development.

Having accepted the theory of contagion and the communicability of tuberculosis, the subject of prophylaxis becomes invested with an increased and all-important interest. It is a problem as broad and intricate as the disease is widespread and insidious, and involves a radical disturbance of many existing domestic, social and financial relations and usages. Realizing the importance of the subject the profession, as well as boards of health and other legally constituted sanitary authorities, are rapidly adopting both advisory and compulsory measures of prevention.

In order to acquaint myself with the work done up to this time by some of the principal cities of our country, in the matter of prophylaxis in phthisis, I recently addressed letters of inquiry to the secretaries of the boards of health of the following cities: New York, Philadelphia, St. Louis, Baltimore, Washington, Buffalo, Cleveland, Detroit, Chicago, Cincinnati and Boston. From New York, Philadelphia and St. Louis, I received printed literature on the subject, consisting of rules, instructions and advice to the profession and laity. From the next five cities the replies were that they had taken no steps in the matter, and from the last three there were no replies.

The literature issued by the first three named cities is based upon the theory of the communicability of consumption, and the preventive measures recommended in the circulars, are chiefly intended to guard against the inhalation of dust arising from pulverized dried sputa of consumptives. Other sources of infection are barely mentioned, and the public is lulled into a sense of false security, by being advised to guard only against one channel of infection when others remain unguarded. The New York Board says: "This matter, spit upon the floor, walls, or elsewhere, is apt to dry, become pulverized and float in the air as dust. The dust contains the germs, and thus they enter the body with the air breathed. The breath of a consumptive does not contain the germs, and will not produce the disease." The Philadelphia Board says: "There is no danger from the mere breath of a tuberculous patient. The risk is from dried expectoration." Medical writers, through our numerous journals, reiterate substantially the same views; namely, that the chief danger of infection lies in the inhalation of dust arising from the pulverization of the dried sputa of consumptives, and that tuberculosis could be easily stamped out if the sputa was scrupulously collected and destroyed.

While I fully admit the great danger from the inhalation of contaminated dust, as described, I also contend that tuberculosis can be communicated by the breath of a person whose lungs are affected by the disease. Not by the breath of ordinary and tranquil respiration, but by the breath in coughing. Let us see how this may happen: the act of coughing consists of several distinct processes; 1st, a long and full inspiration of air; 2nd, closure of the glottis and epiglottis to retain this air; 3rd, a powerful contraction of the muscles of expiration, placing the air in the lungs under a heavy pressure; and, 4th, a sudden opening of the glottis and epiglottis, accompanied by a forcible but momentary explosion of a blast of compressed air; and then a succession of sudden closures and re-openings of these organs, until the entire volume of compressed air in the lungs has been expelled in a series of forcible jets, carrying with them the offending matter in the air passages. This is followed by other full inspirations and the succeeding spasmodic expiratory blasts until the paroxysm of coughing comes to an end. The flapping movements of the epiglottis, the rapid vibrations of the vocal bands and mucous membrane of the larynx together with the friction of the forced jets of air, lash a large quantity of the escaping pus into a spray or mist which is blown into the apartment of the invalid. In other words, the human larynx, during the act of coughing, is a living atomizer or nebulizer, by which the atmosphere

surrounding a consumptive person is constantly impregnated with atomized pus, carrying with it myriads of tubercle bacilli. This spray floats like a mist, and is wafted about the sick-room by every movement of the attendants, bed-clothing, curtains, fans, etc., and is, of course, inhaled, to a greater or less extent, by every person occupying the apartment. Being moist and fresh from the diseased lungs, it is far more infectious than the dust from dried sputum, in which many of the germs of the disease have lost their vitality by long continued desiccation. When we consider how incessantly the paroxysms of coughing occur in many cases of phthisis, and how, in almost every act, some pus is expelled from the larynx, it is no stretch of the imagination to conceive of the sick chamber of the consumptive to be literally filled with a mist of atomized infection.

Both the Boards of Health of New York and Philadelphia declare, in their circulars to the laity, that consumption can be largely prevented by simple and easily applied measures of cleanliness and disinfection, and have formulated a system of very excellent rules of asepsis and antisepsis, in the treatment of the sputa; but in omitting a warning against the danger from the inhalation of atomized pus, invisible to the unaided senses, they tend, as before stated, to delude the public into a false sense of security, while yet in the midst of great peril.

In view of the results of the experiments of Tappiener and others, in communicating tuberculosis to the lower order of animals by simply causing them to inhale an atmosphere impregnated with atomized phthisical pus, the possibility, and, indeed, the great probability of the disease being propagated from man to man, by the breath, should not be ignored. This channel of infection has hitherto been either unsuspected or overlooked, and it behooves our sanitary authorities, as well as the profession, to warn the public against it. The subject is certainly worthy of further investigation, and it is with this view that I humbly suggest it to the consideration of my fellow members of this Association.

By prophylaxis we understand the practice of all measures to prevent the occurence, and arrest the progress of the disease. Regarding consumption as a zymotic disease, engendered by a pathogenic microbe emanating from an affected individual, *isolation* is obviously the most effectual prophylactic measure. But, as man is a gregarious animal, perfect isolation is impossible, because it would imply that every affected person should live the life of a hermit. Isolation by segregation, then, becomes the next best method. Separate wards in hospitals, almshouses, and other eleemosynary institutions, as well as hospitals for the exclusive use of consumptives, could be established. Under a more enlarged and comprehensive application of this idea, communities of consumptives could be organized. If legislative bodies possess a constitutional right to appropriate the public funds, which few people now doubt, for the establishment of asylums for the insane and epileptics, with the view of protecting the community against injury to the person and damage to property, surely the commonwealth would have an equal right to establish homes and communities for consumptives, to protect its citizens against the ravages of this fearful scourge —tuberculosis.

An ideal institution of this kind would embrace, in the first place, a large tract of land in some healthful locality, upon which, as a nucleus, a home for these invalids could be erected, which would, by more or less rapid accessions, develop into a community. The land would afford ample opportunities for out-door exercise in various agricultural and horticultural pursuits; and for the organization, from time to time, of small industrial establishments for the employment of such of the inhabitants as were skilled in the mechanic arts. In this way the institution might be made to become almost self-sustaining. This would, however, be only a trifling consideration compared to the more important results that would accrue from the isolation of the sick from the healthy; from the excellent hygienic advantages afforded to the inmates; from the superior facilities for the practice of asepsis and antisepsis; and from a more systematic and methodical therapeutic treatment than is usually followed, at least among the poor, in private practice.

Domestic relations would necessarily in most instances have to be disrupted, but this disadvantage would in a great measure, be compensated by the establishment of

pleasing social diversions; and life in such a community would not be nearly as forlorn and dreary as might at first thought be supposed. Many perplexing questions would, no doubt, present themselves in such an enterprise, which only time and experience would enable us to solve; but the experience we have already obtained in conducting asylums for the insane and other public institutions, would be an invaluable guide to us.

Ventilation, probably, comes next in importance to isolation as a prophylactic measure. Recognizing as the two chief sources of infection the nebulized pus and the dust from pulverized pus, both of which are almost as evanescent as air itself, it is evident that a frequent change of the air in the apartments of the sick would greatly reduce the danger of infection; besides affording the vitalizing influence of pure oxygen, and averting the baneful effects of carbonic and other expiratory gases. The old-fashioned open chimney-place, with a grate-fire, stands at the head of ventilating devices for dwelling-houses; where this is not available, a large flue with a wide funnel-shaped opening, pendent from the ceiling or projecting from the wall, having a heated stove-pipe running along the axis of the flue to create an upward current, would answer as an efficient substitute. Into either of these devices, a tide of air is constantly converging, and if the invalid's bed, or chair, were so placed as to enable him, while coughing, to simply direct his face toward the open mouth of the ventilator, the nebulized pus, at least, would almost all be carried out of his apartment.

The importance of asepsis, as at present generally taught, in carefully collecting and destroying by fire, all the visible and tangible purulent expectoration, and other measures of scrupulous cleanliness, cannot be overestimated. Neither is diligent antisepsis, by various agents and methods too numerous to recapitulate here, of much less importance. By this measure we not only destroy the contagion deposited upon the walls, furniture, clothing, etc., in the shape of nebulized pus, but also that of dust which will arise notwithstanding the most careful asepsis.

It may be rash to prophesy that the time may come, and it is to be regretted that it has not yet come, when the infant science of bacteriology, aided by chemistry, will discover some volatile and diffusable agent which will be germicidal to the bacillus tuberculosis but innocuous to human life and health. The hope that such a discovery may yet be made is not altogether visionary; but until it is made, it appears to me that there is no certain way, except perfect isolation, of escaping the danger of infection in pulmonary tuberculosis, from the inhalation of atomized pus, unless it be by artificial immunity.

Prophylaxis by the conferring of immunity is a theory which is at present gaining great favor in the profession. Nature is constantly reminding us of and trying to teach us this principle of immunity, by showing us, in our daily observations, how, in the case of a number of contagious diseases, one seizure produces an immunity against another. Long before the time of Jenner, the profession utilized this principle by the practice of inoculation against smallpox. Jenner improved upon this practice by using the virus of variola only after modifying it by passing it through the blood of the cow, and thus securing the inestimable advantage of depriving it of its variolous contagion.

For upwards of a century after Jenner's discovery of the vaccin virus, until Pasteur's announcement of his antitoxins for anthrax and hydrophobia, the profession rested almost in a state of lethargy in relation to the evolution of the principle of immunity. With a knowledge of the existence of natural and acquired immunity, and of the protection afforded against smallpox by vaccination, it is surprising that science was not stimulated to make any advances in this direction during so long a span of years.

Professor Koch's world-famed tuberculin, although it has failed to sustain the claim originally made for it, as well as the recently introduced diphtheria antitoxin, are important steps in the direction of prophylaxis by immunity. The antitoxins, it is true, are intended to cure diseases; but it is evident that if they should prove antagonistic to the morbific agents already developed in the economy, they would prove equally effectual in inhibiting their inception, and thereby confer immunity. The theory of artificial immunity appears to be a plausible one; and although many failures may yet be expected in the numerous experiments now

in progress and hereafter to be inaugurated, the scientific mind has been thoroughly aroused to the importance of the subject; and it is hoped, as well as believed, that the time is not very remote when many of the contagious diseases, especially the fearful malady under consideration, will be shorn of their power to devastate whole families, communities and nations.

CONTRIBUTIONS TO THE STUDY OF THE ETIOLOGY OF HEPATIC CIRRHOSIS*.

N. KABANOFF, Moscow.

I have collected, during the last two years, fourteen cases of vascular cirrhosis of the liver, and in ten of them there is a history of alcoholism. The opinion, therefore, that alcohol is of importance in the etiology of cirrhosis seems justified, apparently, but only apparently. One remark ought to be made in the beginning. The use of alcohol is, at present, so wide spread that among adults, men especially, one can scarcely find ten per cent. who do not take it. It is not surprising that alcoholism should be often noted in cases of cirrhosis.

Of our fourteen cirrhotics, thirty per cent. do not take alcohol at all. Of the ten alcoholic cirrhotics, we must consider that five only have really abused alcohol. For example, one of the patients, the janitor of an apartment house, has used alcohol only during the last nine years, being now thirty-nine, and in doses of only one one or two small glasses of *eau-de-vie* occasionally before dinner. Again the wife of a shoemaker, aged thirty-eight years, married at the age of eighteen, who, during the first few years of her married life, and then only on visits, has used alcohol to the extent of five or six little glasses, once or twice a month. Also a bookbinder who, from time to time, drinks a few little glasses at great festivals, or when in company, and who has rarely gone so far as to drink half a bottle. Also a cook drinking *eau-de-vie* to the amount of a bottleful in a whole day, once a month after a washing, who has never been drunk and who, for the last seven years, after ceasing to do washing has not drunk at all. Finally, a terrace-maker (sodder?) who would drink every day, after hard work such as laying turf, a cup of tea with *eau-de vie*. This last is the only case in which the use of alcohol verges on abuse.

But what is much and what little, with regard to alcohol? It cannot be measured in numbers of glasses. For one a small glass is an abuse, for another it signifies nothing. Our sodder belongs to a class of peasants whose use of alcohol is more or less habitual. His father drank *eau-de-vie* moderately, and he has doubtless acquired by heredity a certain immunity against the effects of alcohol. He has never been fuddled by his cup of *eau-de-vie*, and rarely, on great feast days, has he become drunk.

Thus, in these five cases, we can not ascribe to alcohol an essential rôle in the production of cirrhosis. The use has been moderate, less than usual, especially if we take into consideration the class of society to which the patient belongs.

Nevertheless, there remain five cases (35 per cent.) in which the abuse of alcohol is irrefutable. But what are the occupations of these patients? Book-binder, janitor of a rooming house, peasant, German mechanic, sodder, inn-keeper, merchant, surgeon's assistant, laborer, cook, a shoemaker's wife, an artisan's wife, and a woman without definite occupation. We must admit that among a similar class of people we would scarcely find less than thirty per cent. who abuse alcohol. Consequently, the percentage of those among the cirrhotics who abuse alcohol scarcely exceeds that among healthy persons of the same class.

Of the five persons who might be said

* From Archives Generales de Medicine. Translated and condensed by A. L. Benedict, A.M., M.D., Lecturer on Digestive Diseases, Dental Department, University of Buffalo.

to abuse alcohol, there are only three whose abuse is carried to high degree, and, curiously enough, in these three cases the hepatic and abdominal symptoms are unimportant. With the peasant, for example, (aged fifty-nine years) nervous symptoms were the most marked (a state of exaltation, extreme tremors, insomnia), while the ascites was very slight and disappeared entirely within five days after admission to the clinic. The liver was very slightly diminished in size and the spleen was not hypertrophied.

In the case of a women, aged fifty-one, without regular occupation, the symptoms were cardiac, and on admission she had no ascites, but it had been present six months earlier. The disappearance of ascites on treatment in another hospital and other symptoms, showed that the ascites depended on a failure of cardiac compensation. The liver is perceptibly enlarged—a fact explicable as part of the same mechanism.

In the most marked case of alcoholism—the merchant, aged thirty-two, whose mother had when he was six years old, begun giving him daily two teaspoonfuls of *eau-de-vie* for his health, and who has drunk a bottleful a day since the age of fourteen—there were symptoms of delirium and of multiple alcoholic neuritis, but a merely incipient cirrhosis of the liver. In the history ascites is not mentioned, and on admission there was only a slight amount of fluid, which soon disappeared. These cases support the proposition that alcohol has no more action on the liver than on other organs. We must bear in mind that the latest and most carefully conducted experiments on animals, have not given a single result in the way of producing an alcoholic cirrhosis. (Strassmann, Aphonassiew, Kahlden.)

Let us now investigate the other etiological factors in the production of cirrhosis of the liver,—syphilis, malaria, etc. These are as follows:

Artisan's wife,—dwelling in a damp basement.

Surgeon's assistant,—a series of acute affections; three weeks of malaria twenty-two years previously; typhus thirteen years ago; during the last seven years, frequent attacks of dry bronchitis. In clinic, there was found a very slight specific lesion at the apex of the lung, and a dry cough without mucus. During his sojourn in the hospital, his temperature very rarely rose two or three tenths, above 37° C. (98.6—99. F.)

Workman,—malaria ten years before; cold and damp dwelling. His cirrhosis was atrophic.

A case in which the use of alcohol was moderate,—rheumatism.

A similar case, — painful mental conditions.

The etiology of hepatic cirrhosis is very similar to that of numerous other diseases. We must conclude that every external evil influence can become a cause of cirrhosis, and that the same evil influence can become the cause of an entirely different malady, or may exist in perfectly healthy persons. We must, therefore, suppose an internal cause or predisposition, acting with the external cause. Ordinarily it is the organism as a whole that is in a state of greater or less vulnerability, according to the greater or less activity of the vital processes. However, all the organs do not participate in the disease to the same degree; such and such an organ presenting a high degree of susceptibility, while another is scarcely affected. Rarely, however, is a single organ diseased. In the particular class under discussion, it is very uncommon to find a cirrhotic liver with no other organ diseased. It must be noted that, owing to the compensatory power of the various organs, there may be a history of health up to an age considerably later than the time of the beginning of the lesion. We must bear in mind in estimating the beginning and the course of the case of hepatic cirrhosis, that the disease antedates, by far, the appearance of ascites, which really marks the beginning of the end.

In five of the cases, there is evidence of hereditary influence. The janitor, aged thirty-nine, was the next to the last child of a man who was a great drinker. Before his military service his health was fair. During his military service in the Turko-Russian war, while about Mt. Caucasus, he had malaria, an acute nephritis and a return of the malaria which, in spite of medical attendance, lasted till after the close of the campaign. After his recovery he settled in Moscow, obtaining a position as janitor—a great change from his peasant life—and married. He had been addicted to no excesses, and did not begin

to drink even moderately, till he was thirty. There was nothing unwholesome about his life except that it was not what heredity and habit had fitted him for. At thirty-nine, three years after the beginning of ascites, he presents a well-advanced cirrhosis.

Case 2. The father and mother of the shoemaker's wife were heavy drinkers, the father having shown œdema of the legs and face for several years prior to his death, which, at the age of fifty-five, occurred suddenly in the street. The mother developed ascites six months before her death. Of twelve children, only three remain. The patient from an early age showed the influence of bad heredity by weakness. Married at eighteen; the first sixteen years of her married life were pleasant enough and the use of alcohol was very moderate. During the last four or five years her husband has taken to drinking heavily, their losses have been severe and she has been greatly depressed. She has had ten children. Here, the external conditions really seem insufficient to produce such troubles as cirrhosis of the skin, a considerable decrease of tissue change throughout the organism, enteritis, arterio-sclerosis and, finally, cirrhosis of the liver badly compensated for; and all this at the age of thirty-eight. In this case better than in many other examples, we can recognize the rôle of hereditary weakness of the system; the hereditary predisposition to various maladies in the development of such and such extrinsic lesions and, in particular, of the congenital predisposition on the part of the liver. It is interesting to note certain anatomical indications of degeneration in the great toes; the metatarso-phalangeal articulations forming a boss on the inner side of the foot. The same anomaly occurred in the father and the oldest brother of the patient. Of her ten children, only the three oldest survive and all of these are in a satisfactory state of health.

Case 3, was that of a noble lady, aged twenty-five. Her father was syphilitic; several ancestors on the mother's side had died with heart disease. From early childhood there was a history of bad health, including diarrhœa, anæmia, furuncles, abscesses, arthritic pains, headaches, etc. She was married four years ago. Three years ago she had an attack of acute nephritis and, the same year, a miscarriage. Otherwise she has remained sterile and showed by the lack of development of the breasts, the anteflexion of the uterus and the conical cervix a failure of maturity. On the foundation of the hereditary syphilis, there was the arthritic diathesis with the cachexiæ mentioned.

Case 4, was that of a laborer with well marked cirrhosis at twenty-eight. His father is a heavy drinker; his mother and a sister died of phthisis; he is the only survivor of six children, the rest having died at an early age. At ten, he had malaria lasting four or five months and recurring occasionally. At the autopsy, it was found that his heart was of only half the normal size, and the liver weighed but 950 grams. This could not be explained solely by the cirrhosis, which involved only the left lobe. There was a genuine failure of development of both heart and liver.

Case 5, was the case of the surgeon's assistant, aged thirty-six. In spite of the absence of alcoholism, he presented an imperfectly compensated cirrhosis of the liver, enteritis, hemorrhoids, emphysema, dry bronchitis, an incipient tubercular lesion in the apex of the right lung, a considerable cutaneous cirrhosis and arterio-sclerosis. A considerable degree of anæmia developed during his stay at the hospital. All this is inexplicable if we bear in mind the external causes only, but it is readily explained by the heredity. His father is a heavy drinker; his mother, after aborting once, as delivered of three children. One was addicted to onanism and died of phthisis at the age of twenty-three; the second is a woman of forty, at present in bad health, with a chronic cough and nervous symptoms; the third is our patient. In the history we note a succession of acute diseases and rheumatism. In short, a predisposition to all sorts of inflammatory processes.

In the following cases heredity is not established as a cause of the hepatic disease.

Case 6, is that of the binder, aged thirty. He shows cirrhosis of the kidneys, vessels, myocardium and lungs, as well as enteritis, œdema of the lower extremities and considerable anæmia. Though married, he has no children. Regarding his parents he can give no definite information, but the existence of a hereditary weakness is manifest.

Case 7, is that of the inn-keeper, aged forty. At twenty-five he was a coachman; for the last several years he has enjoyed prosperity. Yet, at forty, he is an invalid, worn out, emaciated, with a considerable emphysema, a confirmed cirrhosis badly compensated, with slight œdema of the malleoli and with arterio-sclerosis. The external causes, including the use of alcohol, are insufficient to explain his condition. We must recognize a constitutional enfeeblement of congenital origin. At eleven he had an inflammation of submaxillary ganglia with suppuration. He married at the age of eighteen and had four children, of whom three have died at an early age. By a second wife he has had three children, of whom two are dead. During his entire life he has been subject to indefinite rheumatic pains. Although we may recognize the causative action of alcohol in his affection, we must also bear in mind that from the age of fifteen he has lived a life entirely different from that of a peasant for which heredity fitted him, and that he has had a superabundance of nourishment and an almost complete absence of physical exercise.

Case 8, is that of the woman without definite employment, aged fifty-one. She has a universal atrophy, including cirrhosis of the liver and kidneys, emphysema, sclerosis of the skin and endocardium, and an arterio-sclerosis of high grade. Thirty-six years ago she had a six months' attack of malaria; fifteen years ago, two acute attacks; she has used alcohol moderately since the age of twenty. As a child she was sickly, and had much trouble with intestinal worms, which cause no serious trouble in a healthy person. At fifteen she had anæmia with headache, vertigo, etc. For the last four years of her life she has lived in a cold, damp place, without means to support herself in comfort. Her organs were evidently in a diseased state when she began her life of poverty, the hard conditions of the last few years serving to bring the symptoms into prominence.

Case 9, the wife of an artisan, forty-one years of age. From her nineteenth to her twenty-seventh year she lived in a basement; at the age of thirty-four failure of compensation was evident. Her condition is that of Case 6, with the addition of colitis and pleurisy with marked dropsy. A congenital enfeeblement is apparent; at fourteen, after her second menstruation, she had acute nephritis; while during her abode in the basement she suffered from continual headaches. Toward the end of each pregnancy, her feet would swell. Pregnant ten times, she aborted five times, and of the five children born alive, two died early. She states that the other three are alive and well. She had sixteen brothers and sisters, of whom twelve died early, and another at thirty-four of an acute mental disease. Evidently the family is tending to become extinct in one or two generations.

Case 10, is the merchant, thirty-two years of age, already referred to as having abused alcohol from an early age. His brother is also a drunkard, and this fact points to a hereditary weakness. His symptoms showed themselves only a year ago when a sudden reversal of fortune, in which he lost about $20,000, was almost immediately followed by loss of compensation. In addition to the hepatic trouble, he has cirrhosis of the kidneys and a moderate arterio-sclerosis.

Clean Thermometers.

Those who are constantly preaching the germ causes of disease are the very fellows who many times are equally as careless as their unbelieving friends. How frequently do we see physicians take the temperature of their patients, regardless of the existing disease, wipe the instrument with their handkerchief, which is the most liable linen to be full of germs, or a towel, or even use the sheet, and carefully place it away in a case prepared with a small amount of absorbent cotton in the bottom to keep from breaking, and unintentionally preserving the germs from time to time, to be conveyed to the next unfortunate, who may be the first patient called upon. This seems to be a very simple thing to discuss, but any reasonable person can readily see the necessity of having his thermometer thoroughly cleaned every time it is used. It should be washed with soap and water, and if any cotton is used in the botton of your case, let it be sublimated cotton and occasionally renew it.—*Charlotte Med. Jour.*

Ice applied to the external genitals (the scrotum in men and the labia majora in women) controls epistaxis and hæmoptysis.

PRECAUTIONARY MEASURES AGAINST PUERPERAL CHILL.

M. F. McTAGGART, M.D., NAPA, CAL.

Considering this subject, the questions present: How far are we justifiable in employing measures for the prevention and elimination of septic deposit during and immediately after parturition? Should intra-uterine injections be resorted to?

Regarding the "Germ Theory" as a logical basis for provisionary expedients against disease; drawing deductions from accumulated knowledge resulting from scientific investigation of the existence of bacteria; accepting the postulate pursuant to the greater mass of the medical profession, that bacilli engender and propagate all infectious and contagious maladies; we are only moving upon the plane from which we receive the impetus, when we resort to intra-uterine injections immediately after childbirth, and such other methods as shall here be advocated to preclude the danger of septic infection during the puerperium. In doing so, I am conscious of the fact that I conclude and act against the brunt of much opposition; though with some concurrence of the best medical authorities.

We have either to consider the element of putrescence as a living germ, *i.e.*, that it is an established fact as such, or we must deem it out and out a nonentity. That it is not the latter, is evidenced by overwhelming proofs of its prevalence in every sluice of contamination. Science tells us it is everywhere. No part of the parturient room, carpets, drapery, bed or sheeting is exempt from it. It is on all parts of the body and is in the vagina.

In the face of these facts, many able physicians, while admitting the truth of the dictum, dispute the propriety of the very remedies or proceedings that are most liable to reach or exclude them, basing their objections upon the suspicion that the benefits to be derived by the precaution will fail to compensate for the injuries that such treatment is liable to produce by acting as an irritant or foreign substance. While others who are convinced of the utility of some such radical measure as a preventive of sepsis, are slow to recognize its application because of similar apprehensions.

We know, however, that when debris of any kind is pent up in the womb, it forms a nucleus for germs, whether it be a portion of placenta, blood-clot, or serum held in the contractile tissue, or whether it be extraneous matter conveyed by the fingers of physician, nurse, or other medium; and that chills, fever and all the symptoms of blood poison, or rather septicæmia supervene. Then it is that the womb is invaded with impunity through forcible dilatation, with thorough drenching and even curetting, with marked benefit. The patient receiving considerable punishment at a time when her life is already menaced by a very exhausting disease. Why then, immediately after delivery, when the uterus is uncontracted, when impurities are being thrown off, when all conditions not only invite but facilitate precautionary steps, why then should we hesitate, upon a mere suspicion of its influencing the mother unfavorably, to avail ourselves of a recourse that should prevent subsequent danger of such grave import to both mother and child.

It has been my practice to act according to the belief that no measure should be ignored nor neglected that gives reasonable promise of immunity from so serious a *morbus* as septic infection; and I am warranted in declaring that every effort in that direction has been requited with ample success. Any one who has met with the accident of puerperal chill—we will call it accident, but I am not sure that it does not deserve the name of criminal negligence—will readily concede the need of more efficient prophylatic measures than those that are usually brought into requisition by the medical profession.

So soon as Koch's developments became patent to science, they were greedily clutched by every aspirant to medical honor. Not so much because of logical presentation, but because the resources of medicine seemed deficient and its achievements offered little more than disappointment or mortification when confronted with grave and serious disorders. The theory seemed possible and the bare possibility offered,

it was hoped, an additional means of accounting for many obscure diseases, as well as suggestions with a trend to save life.

Now, admitting the existence of bacteria as an invulnerable theorem not needing props from any quarter to substantiate it, we recognize the propriety and *absolute necessity* of resorting to such measures as will prevent invasion by them or will destroy them when present.

On going to the chamber of the parturient women, if there be time before the child is born, the nurse is instructed to thoroughly drench the vagina with creolin, lysol, or other sterilized solution, in every part that the syringe can reach by various shiftings of its position. If my presence is needed because of threatened delivery, I frequently repeat this process myself with water as hot as the patient will bear, until the presentation of the vertex implicates danger of flooding the face, which must be carefully guarded against. By this operation the parts are cleansed; the contracted or rigid cervix is dilated; the perineal muscles are relaxed —hence greater protection against laceration of cervix and perineum is secured. It many times prevents the employment of chloroform—which by the way is an excellent agent and one we do not hesitate to use—but by this means its requirement is in many instances avoided, and therefore its unpleasant after effects, which, in some cases, retard the recovery of the patient, or distress her, are obviated. It insures to the parturient a safer accouchment, relieves pain, comforts the mother and secures to the infant exemption from sore eyes—a frequent result of vaginal infection.

Further, it liberates placental adhesion through the engorgement of the utero-placental arteries by reason of liberal application of heat, and their subsequent contraction, a resultant of its discontinuance. Thus facilitating the removal of the placenta, it is more liable to be expelled intact and with much less risk of post-partum hemorrhage. After the expulsion of the placenta to make sure that the uterus shall contain no element of infection, a finger, or hand if necessary, is passed to explore and dislodge, and the organ is then freely flushed with hot antiseptic solution. I use a "Kelly" rubber apron if possible, from the beginning of active labor to its completion, with a view to keeping the patient's robes and bed clean during the whole process, and to leave her so when all is done. This effected, the genitals are dressed antiseptically by cleansing, drying and applying medicated cotton pads. The nurse is instructed to change the dressing and to douche the vagina frequently; occasionally finishing with a large cup of strong coffee as a deodorant and stimulant. This keeps everything sweet and promotes functional activity of low intra-vascular pressure.

Where all the proceedings detailed for conducting accouchments are efficiently carried out, I am satisfied from experience and observation that puerperal fever, eclampsia and the need of forceps, become far less frequent. Besides the mother is not only shielded from the danger of infection, but if lacerations have occurred they will be less in extent and with greater certainty of healing. But unless the hands and everything which comes in contact with the maternal organs be scrupulously clean, such a process will fail of accomplishing the hoped for results. If microbic manifestations appear we have to employ the most active agents the tissues will tolerate to obliterate them. To illustrate the necessity of strict attention to the requirements mentioned, I cite from my notebook, out of many instances, but three cases which, perhaps, will suffice to indicate the merits of the proceedures urged and will attest the value of prompt action in emergencies.

A lady, age thirty-six, mother of three children, had been confined by a midwife two weeks prior to my being called to her sick-bed. I was summoned in haste. I found her with a temperature of 105°. She had no pain. Breasts were yielding thick, green milk, which induced vomiting and enteritis in the infant; respiration was labored; pulse soft and compressible; tongue furred and dry; bowels torpid and urine heavily charged with urates. She thought she had been making a good recovery until within the last three days. Chills, fever and lethargy preceded by insomnia has dictated the need of a physician. Digital examination of the uterus disclosed nothing abnormal; but feeling confident that the cause lay in that organ, the cervix was dilated and a small, fragile, foul-smelling portion of placenta was dis-

lodged. The womb was thoroughly irrigated with peroxide of hydrogen (15 Vol. diluted one half with water) the irrigation being completed with a strong infusion of coffee. In two hours the temperature fell to normal. Second day temperature rose to 101.3°. Irrigation was repeated with creolin solution and the temperature fell to normal. The lavage was continued three days longer, the temperature remaining normal, and patient made a rapid recovery.

Case II.—I was called in consultation to a mother of seven children. Infant was three weeks old and feeding from the bottle. The attending physician admitted having used no special precautions during accouchment, but assured me that the placenta had been removed entire. Her temperature was 103.5°. The breasts were inflamed and nodulated. There was tenderness of the abdomen, and a heavy fetor from the vagina. As we could detect no other cause, it was at once referred to a septic uterus. The cervix was dilated, resulting in the disclosure of numerous minute, friable fungoids adhering to the endometrium just above the os internum, and from which issued a puriform discharge, with an intolerable odor. The uterus was thoroughly irrigated, then curetted and all debris completely flushed out. In a few hours the temperature fell to normal, never rising thereafter but twice. A lavage once a day was kept up for five days, and the patient was up on the seventh day after I was called.

Case III.—A primipara, aged nineteen. Eleventh day after delivery I was summoned by her physician and found temperature 104°; headache; breasts swollen, caked and very painful; cervix and perineum both lacerated. The bowels had judiciously been kept open with aperients. The uterus was tender to the touch, as was also the abdomen, and was suggestive of peritonitis, while the lochial odor was very offensive. Without dilatation, the irrigation, as in the former cases, was resorted to with like results. The lacerations would not heal, however, and were afterward repaired, requiring two different sittings for the operations, the perineum being torn through the sphincter.

In these instances—and I have notes of others, perhaps of greater significance, urging a place in this article—no special care had been taken to protect the patients from infection. There was no possible doubt that septic deposit was the sole element of disturbance, since antiseptic treatment of a radical nature so promptly proved the remedy to save the patients. I know it may be urged, and it is, that many confinement cases do well without any such provisions. In fact, where everything has seemed unfavorable, even to the extent of placing old, dirty rags, portions of soiled quilts—a nest for germs—and all sorts of refuse cloths under the sheet of the woman to absorb the "muss," as is often done. At the same time it may be noted that those cases were in a condition of health to resist the encroachment of microbes, and that a delicate organization or a diseased constitution is more liable to furnish a nidus for bacteria, than a healthful one, and not knowing just where to draw the line of demarcation between such health and disease, it were better to use such precautions in all cases, than to sacrifice one life in a life-time of practice by an omission. It is important that the nurse, too, be instructed relative to these matters, and in leaving a case of confinement or sickness that she should bathe her person in antiseptic solution, fumigate* her clothes and give especial care to her hands. Unfortunately, in families where cleanliness is subservient to the conditions of poverty, the best efforts of physician and nurse may be frustrated and successful results be impossible.

Papain for Tapeworm.

Roberts Bartholow (*Med. News*) reports a case in which, after failure of the usual remedies for tapeworn, a parasite twenty-five feet in length became dislodged and was passed after the use of papain, in ten-grain doses, three times a day after meals. The worm had not undergone solution, but Bartholow thinks the drug had exerted a toxic influence upon it.

* The fumigation may be done by burning a teaspoonful or more of buhach powder on an iron shovel, and under the garments in a closet. This kills all of lower forms of life. A house may quickly be cleared of mosquitoes by burning a little of the powder in the rooms. These insects swell up and die. Flies are not so affected by it; they become intoxicated, however, and drop to the floor where they may be swept up. One of my routine preliminaries in fitting a room for operation, is this fumigation. Touch a lighted match to the powder and it will burn steadily till consumed. The odor is not offensive, nor is the smoke intolerable.

PRACTICING MEDICINE.*

J. McF. GASTON, M.D., ATLANTA, GA.

The invitation of our president to relieve him of a part of his onerous duties on this occasion was accepted in view of the fact that he had labored incessantly during the closing session of our college, not only filling his own hours, but taking the hours of every other member of the faculty who would consent to yield the time to him. I am under special obligation to him for taking my place while I was off duty for a month suffering from the despotic grasp of the grippe.

The great controlling influence with me was, that my venerable chief would be relieved of his burden by a younger member of the faculty. He and I were students together many years ago at the University of Pennsylvania; but it should be remembered that he was one of the oldest and I was one of the youngest in the class. Thus it turns out that with the motto, "*Virtus in arduis*," he is working still, under the accumulation of years, flesh and honors. In the meantime I am renewing my youth with the multiplicity of various duties devolving on me; and we are both striving, in season and out of season, to keep up with this progressive age and our youthful colleagues.

A comparison of the facilities for medical education half a century ago, which passed under our observation, and were noted by us in due form, with what preceded that era, and what has followed, may prove profitable to the graduating class.

My limited time was to be occupied with a strictly professional view of this period, as my distinguished friend who was assigned the duty of making the general address on this occasion, was expected to afford a feast of reason in discussing matters of general interest to this intelligent assembly of ladies and gentlemen. A large proportion of those here to-night have undoubtedly been attracted by the reputation for erudition and eloquence of the Hon. W. C. Glenn, but indisposition prevents his appearance this evening. Not being capable of entertaining this audience with the rich cullings of literature, I shall content myself with briefly noting some matters for the guidance of those who are about to enter upon the practical work of treating the ills which flesh is heir to in this world of pain and suffering.

It may not be out of place at the outset to note that our small list of graduates on this occasion is due, as already stated by the Dean, to the inauguration of a three years' course of lectures, with six months for each session, for graduation in the Southern Medical College.

Formerly our students received the degree of M.D. after two sessions of five months each, and by great diligence and painstaking many of them have attained a fair measure of proficiency in their preparation for the practical work of the physician. But it is evident that by a graded course of three years, in which the first session is devoted chiefly to rudimentary branches, that more satisfactory progress is made subsequently in the higher order of medical education.

The old fathers of medicine in by-gone days, such as Hippocrates, Boerhaave, Galen, Harvey, and their followers, were supposed to know all that was available of the curative art, and, indeed, gave a stimulus to subsequent investigators of great importance. But their work reminds me of a Thompsonian practitioner who flourished in my section during my boyhood days. He had a mania for doctoring his patients with lobelia and cayenne pepper, while they were immersed in hot water baths, in the presence of an old negro woman, who became quite an adept in all the details of the practice. On one occasion when Toney, the husband of the woman, was expatiating upon her great achievements, he remarked with emphasis: "Bless my soul! Mars Dan'l done teach Fanny more than he knows hisself." So it was with those old worthies of early times; they taught the generation which succeeded them more than they knew themselves. At that period all was empirical in medicine, and little was at-

*Address to the graduates of the Southern Medical College, April 3, 1895.

tempted in practice which did not have the sanction of high authority. But gradually the professional dictum came to be set aside, and the physician began to look around him for new fields of investigation. With Harvey's discovery of the circulation of blood a new light dawned upon the medical world, and the fact was impressed upon the observers of results that they were not bound down by the records of the past. Independence of thought and action led to individual investigation; and "thus saith the record" was replaced by a large accumulation of observations in the different fields of medicine.

In the course of events there came forth Bell, Sir Astly Cooper, Goode, Cullen, Marshal Hall, Velpeau, Physick, Valentine Mott, and others no less original and progressive in medicine and surgery.

Among the earliest organized movements for promoting medical education in this country stands the time-honored University of Pennsylvania. It was my privilege to receive instruction there from Chapman, Horner, Jackson, George B. Wood, Gibson, Hodge, and Hare, who were held in high esteem by the large class of students who attended their lectures at that early day.

This was the medical Mecca to which pilgrims flocked from all parts of the United States, and also from other portions of the world, being the great center of medical instruction.

Being impressed with the vast field for advancement in medical knowledge offered at Philadelphia, yet with that State pride which predominated in everything at that day, I was influenced to return to the Medical College of South Carolina to take my second course of lectures, and receive my degree of M.D. A faculty no less distinguished than that of the University of Pennsylvania filled the different professorships at that time in Charleston; and the faithful teaching of Dickson, Geddings, Holbrook, Moultrie, Prioleau and Shepard are vividly recalled by me. In purity and eloquence of diction, the lectures of Dr. Dickson on the practice of medicine have never been excelled; and he was afterwards called to fill the same chair in the Jefferson College of Philadelphia, sustaining fully his high reputation.

Notwithstanding the celebrity of these distinguished professors, which placed them far in advance of the false theories and vain speculations of olden times, it is evident that they had utterly failed to grasp all the principles which lay at the foundation of true progress in teaching.

The advances which have been made in the past fifty years in all departments of medical science, are so stupendous, that should a professor of any branch taught in the curricula of that period be called forth to observe the course of instruction in the better class of our schools, scattered broadcast over this vast field of progressive education, he would stand aghast at the advancement. If the attainments for graduating with the title of M.D. formerly, were compared with the achievements of those receiving the degree of M.D. from our schools of high grade at the present day, the latter-day graduates would be proved to have far greater proficiency in all that pertains to the discharge of their professional duties. I don't hesitate to say that a sufficient number of graduates from the Southern Medical College could be selected each year to fill the professorships in every department more satisfactorily than they were filled by those holding these chairs fifty years ago. Yet it must be remembered that you are only upon the threshold of true progress. If any of us have gained recognition in the medical profession, it has been by dint of diligence in study after graduation, and I would urge upon each of you higher efforts after graduating.

It has been found most conducive to progress in practical attainment for the graduate to spend the first year or two after receiving his degree of M.D. as interne of a well regulated hospital, and these positions are considered so desirable, that some of our medical colleges make the assignment as internes to a hospital, prizes for those who have the best records upon examination. The importance attached to the advantages of securing these appointments is manifested in the number of graduates from our college who have been assigned to duty as internes in the Grady Hospital. My advice to the members of the present class is that any of you who can make it convenient to spend at least one year in this work should take the requisite examination for securing one of those places. I am pleased to note that the Grady Hospital is a well conducted institution.

The grand element of advancement in knowledge offered by the Polyclinic or Post-graduate schools, should enable every new-fledged doctor to apply the instruction which has been received in the medical college, and those who graduated under the old regime had not the facilities for the practical observation of the treatment of medical and surgical patients which are presented in the well organized and splendidly equipped hospitals of the present day. While much has been accomplished by faithful working in laboratories of different kinds and by experiments upon living animals, for the elucidation of biological problems, accurate observations of the progress of disease in the human subject and making records of their data for future reference is far more important to the practitioner.

It is desirable for the graduates to realize that, in receiving their diplomas, they have not learned all that is requisite to acquire for the practice of medicine. In other words, they do not know it all, and it is important that they should know their ignorance. It is thus essential to get a certain amount of knowledge to understand your shortcomings, and to appreciate what further must be learned to fit the graduate in medicine for the proper exercise of his professional duties. You are taught in college all the fundamental principles which are requisite for the degree of M.D., and to qualify the physician to enter upon his work in accordance with the laws of the land. He is fitted thus to take charge of the treatment of cases of diseases, and yet he must inform himself as to what has been done by others under similar circumstances.

Some of you may have read the record of the experience of the lamented Dr. Marion Sims, upon first entering upon the practice of medicine, and his trials and tribulations in undertaking the treatment of his first patient. We must presume that he was well equipped with the teachings of the professor of practice in the medical college where he received his degree of M.D., and yet he was at sea completely in applying this instruction to the case in hand. After reading all the books which were available, his mind was in a state of confusion worse confounded, and he called in an experienced practitioner, to help him out of his dilemma. With similar results in other cases, he became so much disgusted that he resolved to leave that location, tore down his sign, and went to another section of the country. His efforts, after leaving South Carolina, and going to Alabama, were crowned with more success, and, by perseverance, with close application, he ultimately attained such distinction, as to be unequalled by any other member of the profession, at home or abroad.

This affords encouragement to all who may encounter difficulties at the outset, to redouble their energies in overcoming the obstacles which may be encountered, and to continue their studies by reading the best authorities in the different departments of medicine and surgery, after entering upon the practical work of treating diseases. Not only should you study books, but observe closely the practice of experienced physicians, and elicit all the information possible, by getting their advice in consultation. It will not suffice to note the practice of others, but the graduate should study his own cases, and read every available book upon the disease under treatment, so as to select the very best remedies for the case in hand. All the accumulated experience of the best authorities in medicine and surgery is printed in a condensed form, for the information of the members of the profession, who are entering upon the untried field of practice, and you should not grope in the dark, when the light may be turned on, by simply opening the appropriate volume. Do not fail to exercise your rational faculties in determining what is best to do, after you have consulted the highest authorities in the matter under consideration, and each must be his own judge for the occasion.

In a consultation, a few years ago, with a prominent practitioner, who had been engaged several years in the duties of his profession, he remarked to me that he envied my experience as a physician and surgeon. In reply, I told him that all which had been acquired by observation, during a rather eventful life, would most cheerfully be exchanged for the chance to know, with his age, and the opportunity to profit, in future years, by what has been recently brought to light.

You have, then, not simply to pluck the fruit which is ripe, but to take advantage of the growing crop, to reap a magnificent harvest in the future. What

those who have gone before you secured by hard work, by day and by night, is laid before you, to be turned to account in the developments of the near future.

The gradual but steady enlargement of the field of medical investigation, corresponds to the tension of a watch spring, which sets out with a small coil, and by subsequent turns, grows larger and larger, and extending from the outer circle, it is connected with the intricate machinery to keep it in motion.

The developments, have gone forward, in the past two decades, with a rapidity which encourages the belief that still more valuable accessions will be made to our practical knowledge, within the next quarter of a century, and those members of the profession are to be congratulated who may have the satisfaction of observing the fully-completed work of this period. The triumphs of the surgery of the brain, the thorax, the abdomen, and the vascular system, will most probably be overshadowed by the magnificent advances in other branches of medicine and surgery.

The interminable list of remedies within easy grasp of the physician by the tact of manufacturers, continues to grow from year to year, and the diagnosis of diseases, through the implication of the nerve centers promises good fruits for the practice of medicine. But the present interest in bacteriology manifested by investigations of the laboratory and by clinical study offers the best prospect of working out good results of a practical nature at no distant day. The relation of cause and effect has, thus far, not reached a point which enables the pathologist to trace certain disorders to a bacterial origin, and the most that can be claimed is the connection of specific forms of disease with definite organisms or with microbes of a distinctive character. But there is hope for the future of bacteriology.

It is a gratifying reflection for the medical philosopher and scientist to point out the separate germs of the various disintegrating processes involved in the aggravated condition of wounds, and to define the special microbes of distinct diseases; but the practitioner is not always prepared to accompany the bacteriologist in such investigations, nor does it devolve upon him to accept the conclusions from his investigation for the application of remedies in surgical cases. After a somewhat careful research of what has been accomplished by the use of the microscope in detecting the different forms of micrococci and noting the discrepancy in the observations of different experts in this department, I am still in doubt as to the role of bacteria. But I am convinced that such micro-organisms and ptomaines have a share in the degeneration of vital structures.

My attitude in regard to the germ theory of diseases has not always been properly understood, but I wish it to be known that the results of investigations with the microscope are fully appreciated, and that the observations of those who are experts in the use of this instrument are accredited as realities. There is no doubt in my mind of the existence of the comma bacillus in cholera, the bacillus tuberculosis, the cryptococcus xantogenicus in yellow fever, the anthrax bacillus in malignant pustule, and other specific germs which have been recognized as accompanying various other forms of special diseases. But this is quite distinct from the proposition to combat these diseases by the use of germicides or to employ agents of this class as prophylactics against the development of disease.

I am on record as stating that all the practical appliances of surgery may be appropriately classed under the headings of Aseptic, Antiseptic and Septic processes. The first embody all those measures which come under the class af prophylactics, and look to the avoidance of hurtful agencies, thus being assured if the measures does no good, it will do no harm. As the term implies, asepsis consists in shunning all kinds of contamination from within and without the body. Antiseptic application in surgery differs widely from aseptic measures in their aim and results. The practice of antisepsis is confined to correcting any tendency to or the development of degeneration and disintegration of living structures, and yet the claim for antiseptics includes measures which, instead of protecting the tissues, lead to septic development.

The employment of antiseptic vapors to correct the supposed vitiated condition of the air surrounding a patient, has long been exploded, having received its death blow from Thomas Keith, at the meeting of the International Medical Congress, in London. Antiseptic washes in operations upon normal tissues have been abandoned

by many who formerly used them, while a large number of the profession, like myself, have never employed them, and are sustained by reports of the most advanced bacteriologists, that they are not simply innocent, but hurtful, by necrosing the healthy tissues. It is held that antiseptics should be reserved for those cases in which septic processes are to be combatted, and that antiseptic surgery ought to be limited to cases presenting septic conditions. Aseptic surgery has supplanted the so-called antiseptic surgery, in most surgical cases.

In accordance with the accredited doctrine of the Rev. John Wesley, that "cleanliness is next to Godliness," the medical profession has adopted the most stringent regulations against filth of every kind, and eschews dirt in all its forms, in surgical procedure, and in the regime of the sick room. Not only is the surgeon and physician, as well as the nurse to be scrupulously clean, but everything about the patient and bed must be kept clean.

The funeral procession of so-called antiseptic surgery is accompanied by a host of mourners, headed by Sir Joseph Lister, and the last rites of the solemn service at the tomb are to be conducted by a white-robed priest of the order of Esculapius, who with clean hands will lay the defunct body to rest, in everlasting oblivion. "*Requiescat in pace.*"

COMMUNICATIONS.

REFLEX IRRITATIONS.*

SAMUEL AYRES, M.D., PITTSBURG, PA.

There are many interesting problems connected with reflex irritations, the correct solution of which would make us Masters of our Art. The ability to recognize, and then to remove, the causes of remote disturbances in the system, would be so desirable to possess that, were one so endowed, his power of healing would be little less than that of the gods.

It seems curious to me, in view of the great importance of this subject, that there is no distinct treatise in the English language, and so far as I know there is none in any other language, containing a philosophical analysis and interpretation of reflex irritations, based especially upon clinical and experimental research. Where, for example, can we find a convincing explanation of the mechanism of production of the vertex pain, or the palmar heat or wrist pain, said to be caused by uterine disease? On all sides the expression *reflex irritation* is used by medical men; perhaps too often in a nebulous sense to conceal ignorance, or to change the subject—perhaps often in a correct manner, but without a real conception of the mechanism involved. Indeed the term has well nigh become an oppobrium to our art.

It would be well at the outset, it seems to me, to have a clear understanding of what is conveyed by the term "reflex irritation." I believe it is agreed to mean an irritation at some point of the body, internal or external, such as an injury, a foreign body, a pressure, or, indeed, a lesion of any character, which produces a disturbance, or pain, or disordered function at some other part of the body, usually considerably removed from the original point of irritation. The primary irritation is to be regarded as the cause and the reflex irritation or disturbance as the effect. Two elements are therefore always present. It will not be forgotten of course, that reflex acts and influences abound in countless numbers throughout the body; indeed this is an organic law of our economy. But these physiological reflexes, such as the contraction of the heart from the stimulus of blood; the peristalic movements of the intestines from the presence of their contents; or the ac-

* Read before the Allegheny County Medical Society, February 19, 1895.

tivity of glands from their accustomed excitants, are not referred to in the above definition. If the symptoms of visceral or other internal disorders were localized over, or in, the part primarily affected, there would be little difficulty in the study of reflex phenomena. We would merely have to search beneath the surface for the cause. But, unfortunately, this is not the case. Instead, there is a veritable labyrinth of nervous inter-communication and ramification, the irritation of some part of which may be transmitted to a distant region and exhibited as pain or disordered function.

But notwithstanding this complexity of nerve irritations and manifestations, may not the question be pertinently asked, whether there has not been in the last decade or so too much stress put upon reflex agencies in the production of disease? In other words, are there not many symptoms incorrectly attributed to distant lesions, or reflex sources; and, on the other hand, are there not lesions whose remote effects are not recognized or correctly interpreted? The first part of the paragraph naturally suggests local or constitutional causes of a disturbance as opposed to reflex causes. To illustrate: A person has pain, or numbness, or some abnormal sensation, in some of the fingers, or a part of the hand. Is the cause of this local, or is it a reflex from the bladder, or uterus, or elsewhere? Or, a poorly nourished girl has infra-mammary neuralgia; she also has menstrual pain and leucorrhœa; is her neuralgia caused by anæmia or by some uterine irritation? Thus we see that no matter which way we turn the subject is fraught with interesting phases. But let us be more specific. What class of irritation shall we first consider? Suppose we begin with the ocular.

It would be trite indeed to more than refer to the reflex mischief alleged to be set up by errors of refraction, muscular insufficiencies, irritations, or other defects of the eye. Headaches galore, occipital distress, frontal pressure, vertigo, nausea, epilepsy, chorea, insanity, etc. Do these symptoms, and still others claimed, actually result from this source? Will astigmation in the left eye, of one-half dioptre cylinder axis vertical and hypermetropia of two dioptres in the right eye, always produce a certain effect in a school teacher twenty-five years of age in ordinary health? Will they produce the same, or similar effects, in twenty women or twenty men, the conditions being about equal in all? Will they not often occur without noticeable effect? If so, why? The answer may be made that the human system is not a fixed quantity, and that such effects cannot be precisely estimated. True, but are there not enough cases of like character from which to deduce some law? Is there such a law governing these alleged reflex ocular disturbances? Will the ophthalmologists please enlighten us?

A few years ago, the startling announcement was made by a New York physician that chorea, epilepsy and insanity are functional nervous diseases caused by refractive errors, the relief of which, by glasses, would cure these disorders. A little later, this versatile physician shifted his position, or sufficiently stretched the margins to include muscular insufficiencies as further causes of these affections—hence tenotomies and prisms would cure what cylinders and spheres had failed in. The New York Neurological Society after a thorough investigation of the above claims, failed to substantiate them; and D. B. St. John Roosa, in a valuable paper entitled, "The Relation of Errors of Refraction and Insufficiencies of the Ocular Muscles to Functional Diseases of the Nervous System,"* completely exploded this theory. He states: "From an examination of 6,455 eye cases, defective muscular or refractive states do not necessarily produce even local disturbances, such as are comprehended under the term asthenopia, inflammation of the edges of the lids, etc., although high degrees of hypermetropia, and moderate degrees of astigmatism, and all cases of mixed astigmatism are apt to do so, sooner or later," But note, he does not say they invariably do. He farther remarks that asthenopia depends chiefly upon two sets of causes, nervous exhaustion and uncorrected errors of refraction. You observe he places a constitutional or general cause first.

In the *Lancet* of October 28th, 1893, H. W. Dodd reports 100 consecutive cases of epilepsy, their refraction and their treatment by glasses, in which he states that of the 100 cases 25 did not require glasses, so they were not prescribed. Of the remaining 75 cases, only 52 secured and wore glasses as ordered. Of these, 52,

*N. Y. Medical Record.

he says, 13 have had no fits since wearing the glasses during periods varying from one year to four months. Three cases remained in *statu quo*, and 36 have improved in a marked degree.

While some of these individual cases show surprising results and seeming cures by the removal of the apparent exciting causes of the attacks, the results are, on the whole, much obscured by the statement that in nearly all cases the usual internal treatment was continued some time after the glasses were ordered. Then again, the period of time of from four months to one year is not long enough to draw conclusions as to cure in epilepsy. It is a very common thing for cases to escape an attack for several months, or even a year, under large doses of bromide, and then relapse later.

Dodd in his summary uses this language:

"Given a certain condition of instability of the nervous system,

"(*a*) Errors of refraction may excite epilepsy.

"(*b*) The correction of the errors of refraction will, in combination with other treatment, in many cases cure or relieve the epileptic condition."

Thus, we see how conditional are his statements, and how uncertain are the figures here claimed; and how, in many of these neuroses, apparently cured by the relief of some peripheral defect, an unstable nervous system is the real lesion, without which the various reflex irritants would fall as harmlessly as drops of water upon a solid rock.

What as to the aural reflexes? We do not hear much of them. But can we not have ear strain as well as eye strain? The muscles of the middle ear, the tensor tympani and stapedius, are, perhaps, quite as delicate as the ciliary muscles. May they not be disturbed in their action, and produce ear strain? Here is a field, it seems to me, for some enterprising otologist. But we know that there are reflex irritations connected with the ear. For example, every one must have heard or experienced the cough that is often caused by pricking in the external auditory meatus, or by the presence of cerumen; and the vertigo and nausea of Meniere's disease are classical.

How shall we approach that prolific field, the nasal and naso-pharyngeal reflexes? It is an interesting one, and a sensitive area, too, as every one knows who has had a pledget of cotton covered with iodine, etc., swept over its mucous surfaces. This never fails to bring the tears, or redden the eyes, or provoke a sneeze—evidence at once of one of the most pronounced reflex upheavals of which the system is capable. What are the remote effects of inflammation of the nasal mucosa, of polypi, hypertrophies, exostoses, rhinoliths, deviated septa, etc.? Since the nasal fossæ are so richly endowed with sensory nerve ends from the first branch of the fifth pair, and from the glosso-pharyngeal and vagus; and since so exposed, they are obviously the source of much local disturbance, whether their reflex irritations are as far-reaching as is claimed is another question.

McBride in his work on "Diseases of the Throat, Nose and Ear," says: "There can be no doubt that at present there is an undue tendency on the part of specialists to seek in the nose, the starting point of various evils. Yet, it cannot be denied that even this position is preferable to stolid skepticism." This writer thinks that nasal polypi do sometimes cause asthma, as first pointed out by Voltolini; and that cases of migraine, nervous cough, supra-orbital neuralgia, swelling of the face, vertigo, and epilepsy are closely associated with conditions of the nose.

Von Stein states that functional affection of the heart, as palpitation and pain, may be caused by nasal irritation. Joel has related cases of œsophogeal spasm cured by nasal surgery. Hack describes a case of Basedow's disease relieved by cauterizing the nasal mucous membrane. Nocturnal incontinence of children has been traced to nasal stenosis by Ziem, Major and Block. Bosworth in his treatise on diseases of the nose and throat, p. 193, says he has seen a number of cases of chorea relieved completely and permanently by the cure of nasal disorders. Sollinger and Fincke report cases of epilepsy cured by treating intranasal disease, and Richardson mentions the case of a lady thirty-four years of age cured of epilepsy by the removal of a post-nasal fibroma. On the other hand, Moldenhauser states that he never met with a supra-orbital neuralgia or simple headache, from a nasal reflex, and Sajous

says exostoses in the majority of cases give rise to no inconvenience unless they extend across the fossa and compress the turbinated bone. Thus, we have the diverse views of different writers on this phase of the subject. What conclusion shall we reach? I fear the same elements of error and haste are to be found here, as in the alleged ocular reflexes.

A neurosis that has been apparently cured, or temporarily relieved by treatment of the nose is not necessarily of nasal origin. It may exist coincidently, and not be thus caused. McBride seems to get at the correct solution of many of these so-called nasal reflex neuroses, in his statement that irritation of the nose may change a nervous center from stability to instability. "Is there any valid reason why the reverse should not take place?" He says: "Is it not probable that, given an unstable nerve center, irritation of the nose may render it stable?" Thus he believes that the application of the electric cautery and other agents to the nasal mucosa often act as counter-irritants, and thus relieve in this manner. In other words, an equally good counter-irritant or derivative applied to the nucha, or temples, or elsewhere, would probably give the same results. In this connection, I may mention the case of Mr. S. as an illustration of the stress that is laid upon some of these reflex sources, as the fountain of all evil to the exclusion of the real cause. Mr. S. was a most afflicted man; mournful and melancholy, nervous, fearful and tearful; with head and body pains enough to satisfy the most enthusiastic specialist, no matter what his field. He had gone the round with the usual results. Sanitoriums, and their baths and waters, had been freely taken internally and externally. In Chicago he had fallen into the clutches of those orificial fellows who discovered the cause of all his lamentations, and promised quickly to relieve him. His rectum was most effectually bored and ballooned, and his anus trimmed "according to Hoyle." But, not being relieved, he in due time landed in the office of an Allegheny doctor, who found his ills all due to some bones in his nose. These were sawed out, and still he suffered as before. In this extremity he came to see me. It was not a very difficult feat to discover that he was suffering from constitutional syphilis, and that this was probably the cause of many of his symptoms. The response to specific treatment, which he had evidently not received before, was altogether satisfactory, and most of his symptoms disappeared; but not all, for these cases rarely get entirely well, as you are perhaps aware. It was a matter of more surprise that there were enough bones left in his nose to saw out.

Another case which was under my treatment, and would by all precedent be regarded as a cure of epilepsy by the removal of the hypertrophied tissue on the turbinated bone, may be referred to. It was that of Mr. S., twenty years of age, who had been epileptic for six months; a fit every week or two without a very clear cause, though he came of a neurotic stock. While examining him I touched with a probe the inferior turbinated bone, when he immediately had an attack. I recommended the destruction of the hypertrophy, which was done under cocaine, and he has had no spell since, now more than two years; but I was careful to keep him on large doses of bromide for several months. I saw this man the other day and he says he has sensations in his head of threatened attacks. I do not believe the hypertrophied tissue was the real cause of his fits, and am satisfied if I had touched his eye, or occasioned any sudden pain, the shock would have originated the spasm, just as the sensitive nasal tissue seemed to do.

Turning now briefly to dental reflex irritation, we find numerous transferred disturbances from this source. There can be no doubt that, in weak, nervous children during early dentition, convulsions, vomiting, eczema, diarrhœa, and other troubles, result from this source. Occasionally the irritation from a decayed tooth, or inflamed dental nerve, is transmitted to the ear, producing well marked earache. Headaches apparently due to dental origin are said to affect chiefly the temples and occiput. How often, though, have we seen whole sets of teeth, and many of them sound, too, sacrificed to a mere suspicion that they were the cause of persistent headaches; when, in truth, the teeth were not in any manner responsible, as is proved by the continuance of the headaches after their removal.

The reflex disturbances of gastric origin are apparently so numerous that time

will not permit more than brief reference to them. The stomach being the center of a nerve plexus whose branches ramify directly or indirectly to every part of the body, it is not strange that, when disordered, it should originate disturbances at almost any part of the system. Its irradiations are transmitted chiefly through the two branches of the pneumogastric and the sympathetic nerves. The altered chemistry of digestion causing imperfect assimilation, and the usual train of dyspeptic disorders, does not correctly come within the province of our subject; for the absorption of these products of defective digestion, and their circulation in the blood, directly cause local irritation at any point of the body; such, for example, as joint pains, or headaches, from uric acid. A good illustration of reflex disturbances from this organ is gastric vertigo. The mechanism of this reflex is believed to be the following: The irritation from the stomach when overloaded is transmitted through the sensory fibres of the pneumogastric to the nuclei in the pons, and from there through other of its fibers which pass to the cerebellum. Since this organ chiefly presides over equilibration, a temporary disturbance of its function, possibly circulatory, occasions the dizziness. Reversing the direction of the irritation, we can readily understand the vomiting which often accompanies vertigo from central derangement of the cerebellum. We shall not stop to explain the frequent production of gastric vertigo through the close connection between the nulcei of the vagus and auditory nerves in the pons, and the resultant disturbance of the labyrinth.

The back pains over the eighth or ninth dorsal vertebra from gastric ulcer are also well-known reflexes; the explanation being that the irriation from the ulcer passes through the sensory sympathetic nerves, and from their ganglia to the corresponding segment of the cord, from which the irritation is reflected through the posterior root nerve to this particular region.

Were there any doubt as to reflex disturbances arising from disordered conditions of the uterus, ovaries, their appendages, the nausea and vomiting of pregnancy would be a sufficient argument to silence all skeptics. But there are no doubts on this subject; the only question is as to what remote disorders are directly the result of irritation in these organs. There is perhaps no problem in the realm of symptomatology more difficult to answer. Those who labor in the field of gynecology will, I think, confirm this statement. That ocular, cephalic, respiratory, cardiac, gastric, spinal, splanchnic, and other transferred irritations, are caused by these pelvic lesions, is a sort of tradition which we all implicitly accepted in our early years, and it still contains much truth. But how often are we doomed to disappointment if we rely solely on the restoration of these generative organs for the cure of the distant irritation.

It is not many years since these viscera were regarded as the *fons et origo* of all evils in woman; but I think the Schneiderian membrane and the ciliary and recti muscles are sharing this responsibility in the last five or ten years. The error of such conclusions is exemplified in the following case: This was a girl of about twenty-two, a former patient of mine, affected with recurrent mania, from whom a well-known gynecologist removed the ovaries with the expectation of curing the mental malady; and both himself and the family actually thought he had restored her, for the operation had quite a derivative effect, and she appeared all at once to get well. But, of course, she relapsed, as these cases always do, and she is still as miserable as she was before the oöphorectomy. The mental disease had not been understood. Owing to the far-reaching influences of sexual derangements in woman, and since pelvic surgery is so comparatively safe in competent hands, it has, I believe, largely become the practice to cure the diseases of these parts, if possible, by way of exclusion, and await results. But it is also true that constitutional conditions, as depraved states of the blood, exhaustion, etc., quickly disorder these organs, and that a course of rest and upbuilding (except there be palpable local disease) may not be time lost.

It was my desire to include a brief consideration of those very interesting reflex phenomena connected with vesical, prostatic, rectal, and urethral diseases; but as I fear to tax your patience, I must forego this part, I will, however, state in connection with this subject, that the numerous reflex neuroses supposed to emanate from phimosis and adherent pre-

puce, can now, at least, be counted in one day; and that we hear much less of the necessity of circumcision, except for hygienic and moral purposes.

I must here distinctly disavow the least inclination to discourage or to interpose any obstacle to the legitimate search for the actual causes of reflex symptoms; but I must insist that one's zeal should not run away with his judgment; and I am opposed to that medical enterprise which would make all the crooked ways straight, and the rough places smooth, in the vague searches for the causes of lesions. But I am free to confess there are extenuating circumstances even in the practice. Were medicine an exact science, and the interpretation of these same reflexes systemized, our investigations would be more exact, and we should know better where to look for the causes of the disease. But since it is not, and since our efforts in one direction after another fail to relieve our patient's distress, we, in our despair, seize upon this, or upon that, as the possible origin; and, like the drowning man, grasp at a mere straw; and so is our most ancient and honorable profession brought low. Unfortunately, my brethren, the fault is too often with ourselves. We do not, or cannot, look deeply enough, and search out the hidden mysteries of disease.

Another interesting question might be touched upon here, if certain disordered conditions present are not believed to be the essential cause of the discomfort or impaired health, to what extent may they act as contributory causes? For example, a case of anæmia has hypermetropia; or a case of uterine disease has also a rectal fissure; will the eye strain in the former tend to use up some extra nerve force, or cerebral energy, so that the nutrition and blood-making organs are retarded in the performance of their functions? It may be so; the question is difficult to answer. Perhaps this is the reason for the general patchwork and repair advised by some specialists. It would seem the wiser course, though, to first correct that lesion which seemed to be the chief cause; and if, after sufficient time and general treatment, the trouble had not disappeared, then remedy other defects.

We must here enter our protest against the premature reports of alleged cures after the removal of the supposed reflex cause. I am sure this is a very prevalent error. Owing to the enthusiasm of many operators, the conclusion is at once reached, after an operation, that the cure is permanent; and forthwith it goes on record. In many of those cases immediately relieved, the psychical effect of the operation, *per se*, or its derivative effect on the circulation, or innervation, is, I believe, no small factor; and from six months to two years should intervene before pronouncing a case positively cured. The temptation to rush into print is dazzling to some, and one reason for the unreliability of statistics.

In our endeavor to reach correct conclusions as to the part certain defects or irritations in organs or tissues may play in this drama of disease, we should bear these leading facts in mind: That constitutional conditions, as gout, syphilis, rheumatism, or other toxic blood states, deep-seated local disease, cerebral and nerve exhaustion, and especially inherited or acquired instability of the nervous system, are of the first importance; and the influence of environment; of meteorological conditions; of various psychical factors, as suggestion, expectation, etc., is not to be underestimated.

Perhaps it may be said that there are three classes of cases with reference to reflex irritations: 1. Those persons of normally robust organizations, on whom ordinary irritations play in vain; their equilibrium cannot be disturbed by anything short of a decided cause. 2. Those persons of unstable nervous systems, who are susceptible to reflex disturbances, but from careful avoidance, and other fortunate circumstances, largely escape their effect. 3. Those neuropathic, sensitive constitutions, so delicately balanced that a single depressing or irritating agent will throw them into an abnormal or pathological state—our neurasthenics and hysterics, for example.

There are many phases of the subject that could have been considered with profit had time permitted. For instance, I have not referred to the mechanism of the reflex arc which enables us to explain many of the more manifest transferred phenomena of irritation. It seems probable that in the production of those complex and unaccountable reflexes, the sympathetic nerves must form the chief media of communication.

NEPHRECTOMY IN A CHILD OF TWO YEARS FOR A SIX-POUND SARCOMA; RECOVERY.*

J. J. BUCHANAN, M.D., PITTSBURG, PA.

The specimen which I here present is a morbid growth of a kidney which I removed by the transperitoneal method from a female child a little less than two years of age. The operation was performed three weeks ago last Thursday, (Jan. 25th), and the child was removed to its home, well, in two weeks from that time.

The history of the case is brief and typical. When she was about nine months old, an enlargement could be felt by the parents in the left side of her abdomen, which gradually increased till it filled the entire left half of the cavity, from the border of the ribs to the groin and encroached far beyond the median line. No urinary symptoms were at any time exhibited. Of late the child had declined in health and weight, and when operated on was in a very debilitated state. The growth was smooth, elastic and slightly movable. It gave all the physical signs of a solid mass. A diagnosis of sarcoma of the kidney was made before operation and the macroscopic appearance of the specimen, taken with the location and history, and age of the patient, leaves little doubt that the tumor is of a sarcomatous nature; but it has not yet been submitted to microscopic examination.

The incision for its removal was placed in the left semi-lunar line, and was rapidly enlarged to an extent sufficient for the extraction of the mass. When the tumor was exposed, it was found to have developed between the folds of the meso-colon; and the descending colon was stretched over its entire anterior surface, from above downward. This condition of affairs has led to the abandonment of the operation by competent surgeons; but since I met with an exactly similar disposition of the bowel over an intralgamentous cyst some years ago, which was successfully dealt with in the manner I am about to describe, I was encouraged to proceed with the enucleation. A longitudinal incision was made through the external fold of the meso-colon parallel with the bowel, and the bowel and the meso-colic covering of the tumor were peeled away till the base of the growth was reached. A satisfactory pedicle was secured, consisting of the ureter and the vessels supplying the kidney. This pedicle was tied with silk and dropped. Only one vessel in the mesentory required ligation, and the entire loss of blood did not exceed an ounce.

An examination of the single fold of meso colon, which was now attached to the descending colon, showed that it probably carried vessels sufficient to nourish the bowel. A temporary packing of gauze was placed in the cavity till the external wound was almost closed. This was finally removed and found dry and the incision closed without flushing and without drainage.

The tumor weighs six pounds, and, it will be observed, springs from the upper portion of the kidneys, which can be easily identified in its lower two-thirds.

In renal tumors of such large size, the lumbar incision (extra-peritoneal) is manifestly out of the question, and the only point as to the incision is its direction. Gerster prefers the transverse, as does Abbe; but, in this case, the longitudinal, in the linea semilunaris proved perfectly satisfactory and seemed to give the freest access both to the surface of the mass and to its pedicle. The Trendelenburg position was employed toward the close of the operation, and no doubt limited the venous oozing and kept blood in the infant's brain.

Although chloroform was used for anesthesia, and the amount and duration of exposure limited as much as possible, an acute bronchitis supervened, from which the child recovered in a few days. No abdominal symptoms appeared; and, as before stated, the child was taken home in two weeks, and has since been perfectly well.

Sarcoma of the kidney is a particularly unpromising disease for surgical treat-

* Read before the Allegheny County Medical Society, February 19, 1895.

ment; and is, of course, absolutely hopeless when treated in any other way. The pedunculated nature of the kidney itself; the fact that a sarcoma, developing in its substance, expands its capsule and forms a definite mass, which can usually be completely removed; together with the fact that autopsies have sometimes shown these growths to have been solitary and without metastases, would render it probable that they are among the most favorable of all malignant tumors for extirpation. On the contrary, however, they are about as unpromising as any growths with which we have to deal. Abbe, of New York, reporting two cases in very young children, still living at periods of one and one and a half years after operation, quotes the statistics of Barth, of Marburg, and Sigrist, as follows: "Barth reports, up to June 8, 1892, collected statistics of 100 nephrectomies for malignant disease, the largest yet gathered, of which 42 died from operation, 20 died from metastases and 38 were cured. The use of the word 'cured' here cannot be accepted in its strictest sense. Sigrist collected 64, with 32 deaths from operation. Nine went one and a half years without recurrence. Five went beyond two years, and one continued well at four years."

These statistics are certainly appalling, and would seem to almost justify the opinion expressed by Mr. Bland Sutton, at a meeting of the Clinical Society, of London, just one year ago. He spoke as follows: "In the cases under discussion, the chances of prolonging life are so very remote, and the immediate risk to life is so excessively great, even in the hands of the most skillful operators, that any surgeon who undertakes the removal of a renal sarcoma in a infant incurs a very grave responsibility, and he would act more judiciously by placing the child under the beneficent charge of a physician."

Mr. Godlee's suggestion, however, should have some weight even with the pessimists, namely, that before the operation be set down as unjustifiable, a series of operations be done on tumors of small size when, of course, the probability of metastasis is the least.

A CASE OF DIPHTHERIA TREATED BY ANTITOXIN.

T. J. ELTERICH, M.D., PITTSBURG, PA.

On Wednesday, February 13th, at 1 P. M., I was called to see Minnie O., aged 6 years; a healthy, well-nourished girl. She had been ill one day. On examination, I found both right and left tonsils covered by pseudo-membranes, tongue heavily coated and a thin serous discharge mixed with blood from the nose. A most pronounced fetid odor was present. The chest, back and limbs were covered by an erythema. Axillary temperature 101½° F., pulse 120, marked dysphagia, headache and general malaise. She had vomited once. Examination revealed nothing abnormal about the heart and lungs.

I rubbed a sterilized cotton swab over both tonsils and sent it to the laboratory for bacteriological investigation. Ordered bichloride of mercury, 1-40 gr. every two hours and stimulants. No local application of any kind was made, neither then, nor at any time during the progress of the disease.

I saw the patient again at 8 P. M. Her condition was about the same as at 1 o'clock; temperature 102½° F., pulse 120, considerable glandular enlargement. Examination of urine sp. g. 1030; acid reaction, no albumen or sugar.

Feb. 14. Condition of the throat about the same as on the previous day, except that the pharynx has become involved. She had passed a restless night with high fever. Temperature at 10 A. M. 99½° F., pulse 120. Report from the bacteriological laboratory, true diphtheria.

At 8:30 P. M., about thirty hours after I had first seen the patient, and about sixty hours after the first appearance of the disease, I injected 10 c. cm. of Behring Serum, White Label No. 2, 1000 antitoxin units. I was assisted by Dr. Chas.

S. Shaw and Dr. J. B. Crombie. Condition immediately previous to injection: Both tonsils and pharynx covered by pseudo-membranes, discharge from the nose, cadaveric odor, temperature 102½°, pulse 120. After having first cleansed the skin with a solution of bichloride of mercury the injection was made by pinching up a large fold of skin, immediately below the right scapula, for this purpose. Dr. Roux's antitoxin syringe was used. No re-action, either local or general, followed the injection. The bichloride treatment was now discontinued, and nothing but stimulants ordered. On the following day I again saw the patient at 9:30 A. M., thirteen hours after injection of antitoxic serum. She had passed a restless night, and complained of pain at the point of injection. However, an examination revealed no inflammation whatever at the point of injection. She was now bright and cheerful; no odor present, temperature 99½° F., pulse 108, somewhat irregular; on inspection the membranes appeared thinner, white in color and at one point on the right tonsil a red spot about the size of a three-cent piece could be seen through the membrane. Slight glandular enlargement still present. Patient taking more nourishment.

At 8.30 P.M., twenty-four hours after injection, a remarkable change had taken place. The greater part of the membrane *had entirely* disappeared, leaving an apparently perfect healthy mucous membrane. No ulceration whatever, temperature 101°, pulse 96 and regular. Patient takes plenty of nourishment.

February 16th, 9.30 P.M., thirty-seven hours after administration of antitoxin, only a small portion of membrane still visible, appearing as thin flakes about the size of a pea on each tonsil. The mucous membrane apparently perfectly healthy, of a pale red color, no ulceration. Patient had slept all night; temperature 98½° F., pulse 90, full and strong. The patient now recovered rapidly, the remnants of membrane disappeared within twenty-four hours, and, to all appearances, the patient is perfectly well; is not anæmic, eats well and sleeps well. The urine was again examined, but no trace of albumen could be found.

Since the administration of the antitoxic serum she has received no medicine whatever, with the exception of a dose of castor oil on the second day. The only unfavorable symptom which was noticed was the irregular action of the heart soon after injection, but which disappeared in the course of twenty-four hours.

I have reported this case, not with the expectation of proving the efficiency of serum therapy. I simply wish to call attention to a few facts; namely, the rapidity with which the remedy has acted, the manner in which the false membrane disappeared, and the absence of any unfavorable symptoms with the one exception, irregularity of the heart's action.

I frankly admit that this case was not of the malignant type, and although a grave form of the disease, a reasonably good prognosis could be given; but at the same time, I must insist that I have never seen a case of such a severe type yield so quickly under the old methods of treatment. Within forty-eight hours after the injection, the false membrane had entirely disappeared without leaving any ulceration whatever. The membrane did not detach, it melted away. The success which I have achieved in this case will warrant me to continue to use this remedy, and especially in the laryngeal form of diphtheria, the treatment of which, we must admit, has been nothing but a dismal failure heretofore.

Cannabis Indica.

This drug, the most active of non-opiate anodynes or soporfics, which was very popular years ago, although little the fashion at present, is deserving of a large share of professional favor, *Med. Rev.* The principal cause which led to its disuse was fear of its toxic power, though there has never been a case of poisoning recorded from its use. Its effect on the system is most marvellous. It causes sleep, overcomes spasms, relieves pain and all nervous irritability, and that too within a few moments after administration. Its soothing and curative effects upon the nervous sympathetic system are great, and there is no one agent that will restore the epuilibrium of nerve motion more quickly. The placidity of repose that is produced by this narcotic is rapid and to the point. Further, it does not check secretion or tend to constipation. It does relieve fatigue and arouse vital action, and can and should be given freely until the effect desired is apparent.

TRANSLATIONS.

ARE MILK-SUGAR AND GALACTOSE DIRECT PRODUCERS OF GLYCOGEN?*

Kausch and Sochin kept rabbits from food for five days so as to reduce the glycogen in the system to a minimum. In the course of twelve hours fifty grams of milk-sugar were given, in concentrated solution. Twelve hours after the last portion of sugar, the animals were killed and the glycogen was estimated. Little was found either in the liver or muscles. This fact was explained on the ground that in rabbits, the ingestion of milk-sugar regularly produces a great deal of gas in the intestine so that absorption is interfered with. Dogs were kept without food for ten or eleven days and then given 100 or 200 grams of milk-sugar. From 8.12 per cent. to 9.82 per cent. of glycogen was found in the liver, 0.33 per cent. to 0.56 in the muscles. After the administration of 100 grams of galactose, 6.73 per cent. was found in the liver and 0.54 per cent. in the muscles. The conclusion is reached that both milk-sugar and galactose, like laevulose, produce glycogen, the quantities of the last found in the dogs not being explicable by decomposition of proteids. The deduction in the management of diabetes is obvious.

TWO KINDS OF BACTERIA THAT PRODUCE BUTYRIC ACID.

Dr. W. Kedrowski has isolated two anaerobic bacteria from mixtures containing butyric acid. One is a slender, motile bacillus, slightly arched, thriving on solid nutrient media, liquifying gelatine, producing a disagreeable gas, coagulating milk in the production of butyric acid. The second is a thick bacillus, growing rapidly on gelatine and secreting a gas of vile odor. It, too, is motile and decomposes milk with the formation of butyric acid.

THE DIGESTION OF SUGARS IN HEALTH.

Dr. W. G. Aitchinson Robertson's article in the Edinburgh *Medical Journal* is quoted. He concludes that cane-sugar is unchanged by the saliva and only slightly inverted by the gastric juice. The more so, the greater hydrochloric acidity of the stomach. In the small intestine, cane sugar is completely inverted by a ferment for which the name invertine is proposed.

[The experience of the translator does not agree with this report. A solution of cane-sugar was warmed in a test-tube with saliva. After about twenty minutes no reduction of copper was found but after an hour, there was an abundant precipitate.]

ACUTE NEPHRITIS FROM INUNCTION WITH NAPHTHOL.

Dr. Baatz reports two cases occurring in boys aged respectively six and eight, who developed nephritis after being treated two weeks for scabies. A 2 per cent. B naphthol ointment was used, the older boy having eight inunctions, the younger six. Four and three grams of the drug, respectively, may have been absorbed. The younger child died.

*Translated for THE MEDICAL AND SURGICAL REPORTER by A. L. Benedict, M.D., from "Schmidt's Jahrbucher."

THE ROLE OF ACID IN PROTOZOAN DIGESTION.

The researches of M. Greenwood and E. R. Saunders are quoted from the *Journal of Physiology*. By the aid of different aniline dyes, they investigated the digestion of several protozoa. Every solid substance introduced, called forth the secretion of acid, but the substances were unchanged by it for a long time. During digestion, the quantity of acid diminished and finally, an alkaline reaction set in. The nature of the free acid was not determined except that bi-carbonic acid was excluded. [And, undoubtedly, from the nature of the reagents used, all organic acids]—Ed. A digestive ferment was not discovered.

THE VALUE OF SUGAR ON MUSCULAR WORK.

The investigations of Vaughan Harley are quoted from the same journal. He first found that the muscular power had daily periods of rise and decline, being greater in the afternoon. A diet of clear sugar supported the strength for muscular exertion almost as well as the customary food except that fatigue was noted earlier. A luncheon of sugar postponed the usual hour of fatigue.

[Pohlman, of Buffalo, has long taught that muscular labor requires carbo-hydrate rather than proteid diet. The translator has found the ordinary cakes of sweet chocolate to be a very convenient and satisfactory luncheon at night.]

THE PHYSIOLOGY AND PATHOLOGY OF READING.

Dr. Goldscheider and his student R. F. Müller, by means of a screen and moveable characters, have exposed letters, figures, etc., to view for a space of about $\frac{1}{100}$ of a second. They found that most persons read by the "word-method" rather than by spelling. Four letters were easily read in the $\frac{1}{100}$ of a second. Complicated and simple letters were read with equal ease and there was a tendency to compare figures and other characters to letters rather than to describe them or to read them as numerals. Words of five letters usually required two exposures of $\frac{1}{100}$ second each before they were comprehended. Such expressions as "Admission positively forbidden" were read in about three hundredths of a second. However, it was shown that only part of the phrase was really seen for similar expressions differing slightly from those in common use were repeatedly misread.

A NEW METHOD FOR STERILIZING LIGATURES.

Mr. Répin, after numerous experiments on the sterilization and preservation of ligatures, finds that the vapor of alcohol exercises a bactericidal action which is capable of destroying all species of micro-organisms. Spores of the greatest resistance, like those of the bacillus subtilis, anthrax, tetanus, etc., are killed by remaining from thirty-five to forty-five minutes in the vapor of absolute alcohol raised to 120° C. Catgut is sterilized by this process without losing any of its properties. Its sterility is then tested by placing it in a tube of bouillon which is incubated for several days. If sterilization is not complete the bouillon becomes cloudy, but if the bouillon remains clear the catgut is rigorously aseptic.

THE PULSE AS AN INDICATOR IN DIAGNOSIS.

Less attention is now paid by medical men to the human pulse as an indicator of diseased states than ever before. This is to be regreted for, although we do not believe that such fine distinctions can be made as were claimed by some of the old authorities, such as being able to tell when a person needed to micturate by the state of the pulse, yet we do think that with a nice sense of touch and with the rational acceptance of other signs and symptoms some of our older brothers averted many mistakes in treatment resultant from faulty diagnosis. Mistakes as often of omission as of commission may be made in this way, for there is no doubt that in almost any diseased state, if there is any possibility of accomplishing anything with remedial agents, it is in its inception.

One of the commonest of errors is the opinion that most diseases must of necessity, run a certain course. To be sure, this is more or less true of some, but cases, even where the tendency is very strong to run a certain prescribed course (under natural conditions,) may often be much modified by treatment. There is no doubt but that there are numerous examples where, when the *materies morbi* is not in large amount, the use of timely remedies may not only modify but abort the disease. This is evidenced very markedly in the statistics so far given of the usefulness of antitoxine as a curative agent in diphtheria. Here the element of *timeliness* is most important.

The well worn proverb *obsta principiis* applies especially to the timeliness of remedies. It avails not to say, "That the cases were of a mild form, and would have gotten well under any, or no treatment." Or to go further and say, as we have heard more than once, "That all cases of cholera infantum that die are true cholera and those cases which get well are not." "That all cases of membranous croup (so called) that get well are doubtful, and cases that die are sure."

In the effort to bring the practice of medicine to an exact scientific basis, so far as physical signs, symptoms and treatment are concerned, the finer diagnostic features are often lost sight of, and the possibilities of discerning them discredited. In fact, the acceptance of fine diagnostic indications, unless accompanied by ample evidence of mechanical proof, is refused, and the assertion of such distinctions relegated to the realm of charlatanism, supermundane quackery, or old fogyism. Followed out to the ultimatum, this means that one cannot diagnose any of these diseases until their characteristic signs and symptoms are written all over the patient, and if one undertakes to diagnose and cure the patient before the disease is well marked, he is met with the cheerful assurance that the patient did not have the disease.

There is such a thing as a diphtheric pulse, in certain stages, as distinctive from croup pulse as night is from day, which, by itself, would contravene any attempt to confuse or ally the diseases. There is such a thing as scarlet fever pulse, a pleuritic pulse, a pneumonia and a typhoid fever pulse—and a lot of other kinds of pulses.

The fact must never be lost sight of, however, that the pulse is only *one* thing *by itself*, and must be taken in connection with a multitude of other conditions, and that fine diagnostic points, not depending on the microscope (which is equally liable to deceive), appeals more to conscience than does any amount of mechanical genius, and that the capability to apprehend such points comes with time, experience and intellect.

On the Toxic Properties of Cocaine.

In a report recently presented to the Paris Academy of Medicine, by Maurel, of Toulouse, it is shown that under the influence of this alkaloid the leucocytes undergo changes: they become spherical and rigid, increase in size, and no longer adhere to the vessel walls. On the other hand, the capillaries contract, and thrombosis and embolisms, particularly pulmonary embolisms, may be produced. These changes may be seen after even small doses of concentrated solutions. His experiments show that intra-arterial injections, made in the direction of an unimportant viscus, are much less dangerous than intravenous injections.

Conception in the Puerperium.

Gruber reports a case which he had under his care last year, of a woman, aged 38 years, who had borne children. She was under Gruber's care for abortion at the fourth month. Four months later she consulted him again in regard to her menses, which had not appeared since her miscarriage. Her abdomen had increased in size, and on the night before her visit she had felt the movements of the child. On examination, a four-months pregnancy was diagnosed. Nine months after the abortion she gave birth to a fully-developed female child. Gruber refers to this as a case of conception during the puerperium.

Chlorine Water in Diphtheria.

Dr. Schubert reports on the value of chlorine water in diphtheria. After an experience of many years he is most enthusiastic on the subject, claiming that no known treatment equals that of internal administration of chlorine water.

He gives a teaspoonful of a mixture consisting of two parts of chlorine water, and one part of distilled water, repeating every two or three hours according to the gravity of the attack., On account of the pungent odor, the nose may be held for smaller children. Gargling or painting the throat is superfluous, but no water should be given after the draught. As a prophylactic the foregoing mixture may be given two or three times daily.—*Dental Med. Wochen.*

Chloral Hydrate in Hæmoptysis.

Dr. J. Palvy has tried chloral hydrate in 15 cases of hæmoptysis. Doses of 15 to 25 grains (1 to 1.6 grams) were injected per rectum. They are reported to have produced an effect within one half to three quarters of an hour. The chloral hydrate, besides, seemed to be also a valuable prophylactic.

CURRENT LITERATURE REVIEWED.

IN CHARGE OF ELLISON J. MORRIS, M.D., AND SAMUEL M. WILSON, M.D.

JOURNAL OF CUTANEOUS AND GENITO-URINARY DISEASES.

Dr. Edward Martin reports a case of

Epithelioma of the Penis.

The author operated on a man sixty-two years old who had been troubled for eight years with a growth on the penis. During this period applications of nitrate of silver were made at irregular intervals, causing a temporary disappearance of the prominence followed by an exacerbation. No history of injury accounted for the sore, and the only family history bearing on the subject was the death of an aunt from cancer of the stomach.

The dorsal lymphatics and the inguinal glands seemed unaffected, and amputation was performed in the usual way with such success that, nine months afterward, the patient is still free from symptoms of recurrence.

The author is not indisposed to regard cancer as communicable and to compare it to tuberculosis; he mentions writers who have shown that it may be due to drinking water, that a nodule may grow after transplantation. Few cases have yet been reported where the source of contagion was evident, but one seems to have shown where a man developed epithelioma of the penis shortly after the death of his wife from cancer of the uterus. Syphilis seems to have no other predisposing power than by furnishing a spot of faulty organization or minor resistance in the scar from a chancre.

So long as an epithelioma has not advanced beyond the warty stage the prognosis is fairly good if operation be performed, but when the tissues begin to break down the chances of recurrence are greatly increased. Sometimes it appears as though inflamed lymphatic glands improve after their source of irritation is gone. Even when the inguinal glands appear macroscopically healthy, the microscope usually shows them to be cancerous.

The main object of the paper is to call attention to the facts that:—it is not possible to deny the possibility of contagion in epithelioma of the penis. When amputation is required the inguinal glands should be dissected out, even if not appreciably enlarged.

Dr. W. R. Pryor writes of

Latent Gonorrhœa in Women.

He believes that in a majority of prostitutes and in almost all women who have had gonorrhœa there may spring up, from irritation of any kind, a discharge containing gonococci and differing only in degree from that due to recent infection.

Microscopic examination of the discharge collected from the cervix, urethra, and the vagina, of a large number of patients, many of whom complained of no local discomfort at the time, led to the opinion that a purulent discharge from the genitals rarely existed without gonococci being present in it or in the tissues producing it. The gonococcus is frequently present when there is no perceptible discharge of any kind, and while the vaginal discharge is rarely free from other pus producing organisms and may even appear to contain no gonococci, the scrapings by a Volkmann's spoon will usually show the tissues of the cervix to contain gonococci generally without other micrococci. The author draws the evident conclusion that one is not able by simple inspection to declare a patient free from gonorrhœa.

The experience of the author is that after a woman is infected she rarely is completely cured of this disease. This is due to two causes; she will not persevere in treatment after the annoying symptoms disappear, and when the cervical racemose glands are invaded it is almost impossible to eradicate the disease from them. The stronger preparations of iodine seems to be more effective for this purpose than other remedies.

Dr. G. Frank Lydston writes of

Leucoplasia and its Relation to Syphilis.

In this article the early mucous sores are not meant, but growths which appear at a later period, often when all other manifestations of syphilis have disappeared, and the author questions whether they may properly be regarded as syphilitic or whether they are not simply manifestations of a weakened system which might be due to other causes than syphilis, and which he has not found amenable to specific treatment.

The growths spoken of tend to form distinct masses or overgrowths of the mucous and sub-mucous tissues, and have received various names, among which "post-syphilitic leucoplasia," or "post-syphilitic leucoplakia" seem the most appropriate.

Habitual users of tobacco may show these growths without being syphilitic and there seems to be the same family predisposition that is often seen with regard to cancer, etc.

The condition leading to these placques may instead produce fissures of varying size with hyperplastic margins or the edges may lose the papillary appearance of a healthy tongue and show instead the smooth surface of mucous membranes.

A more serious variety tends to form nodules throughout the tongue and the step is a short one between these and cancer and they are best treated when this fact is remembered.

The author concludes that we must remember:

1. The possible existence of a certain degree of the original trouble—syphilis.

2. The question whether syphilis has not been eradicated, in consequence of which syphilitic treatment is to be avoided.

3. The relation of previous antisyphilitic treatment (mercury) to the lesions present.
4. The existence of trophoneurosis either as a result of syphilis, its treatment, or more probably of idiosyncrasy.
5. The relation of local irritants.
6. Most important of all—the lesion is to be regarded as possibly threatening to become a malignant neoplasm.

General tonic treatment is advocated and the possibility that small doses of antisyphilitics may also be required, mentioned. If operative treatment is attempted thorough removal must be carried out.

Dr. I. N. Bloom reported an

Obscure Case of Cerebral Syphilis.

The patient was a man thirty-five years of age who had suffered from iritis, enlarged cervical glands, mucous patches, etc., but who could give no history of primary sore, and whose wife remains free from any specific symptoms.

While on a business trip he was without warning taken with a sort of semi-stupor and a disinclination to leave his bed. He was seen by a physician who saw nothing of importance in the case, and the man in a few days moved to another town and then to a third and so on for four weeks, until finally word was sent to his relatives and he was brought home. When seen by the author he was in a lethargy, could be made to sit up, feebly answer questions, etc. His pupils responded to light. His face up to the forehead presented a yellowness or cachexia like that seen in cancer.

Active syphilitic treatment caused rapid disappearance of these symptoms. The patient is now receiving daily one drachm of mercury by inunction and three doses of ninety grains at each of potassium iodide.

PERISCOPE.

IN CHARGE OF WM. E. PARKE, A.M., M.D.

MEDICINE.

The Ice Bag as a Cardiac Stimulant.

A writer in *La Medicine Moderne* is quoted in *La Province Medicale* as saying that the application of an ice bag over the heart, according to Dr. Jullien, is a powerful therapeutic measure. It seems that in 1887 M. Jullien read in the *Gazette delle Cliniche* an essay on this subject by Dr. Silva, and was struck with the author's conclusions. Experimentation upon animals has shown the possibility of raising the blood pressure rapidly from a hundred and twenty millimetres to a hundred and seventy and even a hundred and ninety, and of diminishing the frequency of the pulsations considerably; and these results had been confirmed clinically. M. Jullien was not slow to verify these observations for himself. One day he was called to take charge of a patient with typhoid fever. He advised treatment by means of cold baths, and transferred the patient, a large and strong youg girl, to the care of a colleague. Soon afterward, however, his colleague's illness rendered it necessary for him to take charge of the case again. It was a grave one, and the febrile phenomena were intense. The elevation of temperature proved rebellious to the use of cold water. Soon there was a typical picture of the ataxoadynamic form of the disease. The patient had lost consciousness entirely and lay on the bed entirely uncovered, in a tetanic attitude, varied only by the certain spasms of the head. The temperature remained all the time above 104°; the pulse had reached successfully 120, 140 and 160. Under these circumstances M. Jullien fancied that the application of ice over the heart might constitute a last resort, and he made bold to carry it out. He admits that it was not without timidity that he placed the rubber bag on the region which scarcely showed the tumultuous and enfeebled beats of the exhausted heart. He watched the pulse closely, ready to stop the attempt at the first signal of danger. But in less than fifteen minutes he saw the number of the pulsations diminish and their amplitude increase; in a short time the almost imperceptible undulations of the artery gave place to more decided elevations. Whenever he removed the refrigerant the alarming symptoms returned immediately, so that after many trials he concluded to leave the ice bag in place for several days. After that the temperature yielded, the cerebral phenomena disappeared, and the patient was out of danger. He is convinced that she owed her safety to the decisive measure which he had adopted. In another case also, he accomplished a result equally remarkable by this means. In conclusion, he remarks that the beneficial effects show themselves in from fifteen to twenty minutes from the beginning of the application, and reach their maximum at the end of an hour. It is true he says, that they are evanescent, disappearing rapidly when the application is suspended, but there is no danger in prolonging it as long as the general condition remains precarious. In some cases, under its action, the height of the pulsation has been observed to be tripled, which means a pulse ampler, fuller, and more tense, with the subsidence of dicrotism, intermittence, and irregularity, and with a longer duration of the diastode. An interesting fact noted is that the effects of alchohol and those of atrophine on the circulation are in a measuee neutralized by the ice bag. This, says the

author, is not astonishing, since alcohol has the property of lowering the blood pressure by paralyizing the pneumo-gastric nerve. This antagonism, he suggests, may possibly be serviceable in some cases of poisoning.

The Mental Symptoms of Cerebral Syphilis. A Clinical Study.

Dr. Frank P. Norbury, Jacksonville, Ill., draws the following conclusions:

1. Somnambulism and allied states; lapses of intelligent conception with associated loss of memory are mental symptoms of cerebral syphilis.

2. Sudden comnolence with ocular spasm or paralysis points to syphilis, when preceded with headache and monoplegia is almost pathognomonic. Headache, quasi-periodical, as defined by Gray with marked insomnia, suddenly ceasing and followed by physical disturbance is due to syphilis.

3. Melancholia or mania when following periodical headaches, insomnia, and somnolence (*a*) with ocular spasm or other form of monoplegia of heterogeneous paralysis is due to syphilis. (*b*) Pseudo-paranoia. By this he means cases presenting all symptoms of paranoia, systematized delusions depending on hallucinations of sight, hearing, taste or smell, with slight impairment of general mental functions is due to syphilis, as we know that syphilis causes isolated local losses of power, and it is noteworthy when the special senses involved that mental derangement usually results. (*c*) Pseudo paresis, characterized by fibrillary tremor of tongue, indistinct speech (partial or complete aphasia), uncertain and trembling gait, with delusion of grandeur, and occasional outbursts of maniacal excitement, pupillary involvement, all characteristic symptoms of paresis, but which yielded readily to antisyphilitic treatment, we can say it was due to syphilis.

4. Class four have had epileptiform and apoplectiform attacks. We find cases in which treatment was undertaken too late. The symptoms are those of terminal dementia, only occurring in patients of previous sound mental condition and with no special hereditary history.

Pathology of Basedow's Disease.

H. Reinhold (*Munich Med. Wochenschrift*) believes the seat of the disorder to be in the thyroid gland, and reports the following case in support of his view:

The patient, previously healthy, contracted the grippe, which was complicated with an acute inflammation of the right thyroid gland. Suppuration did not occur, and the swelling and fever soon disappeared. During the fever the pulse was rapid; became normal, however, when the temperature returned to normal. Patient recovered and returned to work. Three months later there was gradual but pronounced simultaneous development of the classical symptoms of exophthalmic goitre. The author maintains, therefore, that it is a typical case of Basedow's disease, resulting from an acute infectious inflammation of the thyroid gland. Reinhold's view is certainly supported by clinical experience, as I distinctly recollect a number of cases which were at first merely simple goitre, but gradually developed the other classical symptoms of Basedow's or Grave's disease. Never did I see among the large number of cases (about thirty) of exophthalmic goitre which have come under my observation, the thyroid gland free from disease and enlargement. While one of the other symptoms which make up the classical picture, the tachycardia, the exopthalmos, the fine tremor or Graefe's symptoms may be wanting.

The Parts that Do Not Grow Old.

In his work on the senile heart Dr. Balfour tells us that there are two parts of the human organism which, if wisely used "largely escape senile failure." These two are the brain and the heart. Persons who think have often wondered why brain workers, great statesmen, and others, should continue to work with almost unimpaired mental activity and energy up to a period when most of the organs and functions of the body are in a condition of advanced senile decay. There is a physiological reason for this, and Dr. Balfour tells us what it is. The normal brain, he affirms, "remains vigorous to the last," and that "because its nutrition is especially provided for." About middle life or a little later, the general arteries of the body begin to lose their elasticity and to slowly but surely dilate. They become, therefore, much less efficient carriers of the nutrient blood to the capillary areas. But this is not the case with the internal carotids, which supply the cappillary areas of the brain. On the contrary, those large vessels "continue to retain their pristine elasticity, so that the blood-pressure remains normally higher than within the capillary area of any other organ in the body. The cerebral blood-paths being thus kept open, the brain tissue is kept better nourished than the other tissues of the body." Who is there among those who have reached or passed middle age that will not be rejoiced to find such admirable physiological warrent for the belief that the brain may continue to work, and even to improve, almost to the very last hour of life?—*Medical Record.*

A Remedy for Insect Stings.

A paint for the stings of insects is given in the *Medical News* in which ammonia is kept in close and prolonged contact with the affected part, and is prescribed as follows:

Aq. ammoniæ	m. cl;
Collodion	gr. l;
Acid. salicylici	gr. v.

A few drops to be applied to each bite or sting.

Early Diagnosis of Phthisis.

Bernheim, of Paris, presented at the Congress at Rome (*Bulletin Medicale*) a paper in which he called attention to the importance

of examination of the spleen and the lymphatic glands in cases of suspected tuberculosis. According to this observer the spleen is always enlarged in cases of tuberculosis, even in the early stages or the disease. This is a new diagnostic point in tuberculosis, and one which should be carefully studied. As a bacteriological test, it is exceedingly valuable in advanced cases, and is also applicable when the disease is in an incipient stage.

Fatal Case of Poisoning by Quassia.

Dr. Ferdinand Venn, of this city, reported the following case to Prof. H. C. Wood, who published it in the *University Medical Magazine* with the subjoined remarks:

On Friday, November 16, Mrs. M. came rushing into a drug store, stating that she had poisoned her child by a rectal injection of quassia for seat worms. She bought five cents' worth of quassia (two ounces) in the morning, poured hot water over it, and kept it on the rear part of the stove all day. In the evening she injected this fluid (about one pint). Five to ten minutes after the injection the child became livid, the lips losing all color; vomited once (contents of stomach), muscles entirely relaxed, and respiration labored. When I saw the child its lips were livid, the skin had a waxy hue, muscles relaxed, breathing labored and shallow, the pulse imperceptible. Death took place about one minute later. I tried artificial respiration, but to no avail. At no time after I saw the child did the heart pulsate; it seemed paralyzed.

I thought the mother might have perforated the intestine with the syringe (a case of that kind having occurred in our neighborhood about a year ago), but such was not the case.

So far as my reading goes there is not on record any case of serious poisoning by quassia. Nevertheless, the experiments of Hoppe show that the active principal is a poison in frogs, especially affecting the nerve trunks and the muscles. Fifteen milligrammes of it have caused a man violent frontal headache, vertigo, excessive nervousness, with pronounced evidences of toxic gastro-enteritis, such as burning pain, vomiting, and diarrhœa. Since receiving the foregoing letter from Dr. Ferdinand Venn I have had him make inquiries as to the possibility of there having been a mistake in the selection of the drug, but so far as can be made out no mistake was committed, and there is scarcely any drug that could readily be mistaken for quassia wood.

Uncontrollable Vomiting of Pregnancy.

Bonnet, (*Revue Obstet. et Gynec.*,) relates a case where the patient was twenty-two, and single. Her first pregnancy went on to term; but in the second, labor was induced at the fourth month in consequence of hyperemesis. During the early part of the third pregnancy vomiting became very severe, lasting a month, and reducing her to an alarming extent When just over six weeks pregnant, a laminaria tent was introduced; on January 14, 1890, the vaginia was plugged with iodoform gauze. For twenty-four hours the vomiting ceased. Next day the tent was removed, and the sickness returned. On January 17th two tents were introduced as high as possible. The vomiting again stopped, returning when the tents were taken out. The five tents were progressively introduced, and left in place for three days. The sickness stopped and did not return. The uterus showed no signs of contracting throughout the course of the above treatment. The patient took food well and grew stout. Seven and a half months later she was delivered of a healthy child at term.

Pathology of Vaginismus.

By Thos. More Madden, British Medical Association (*Med. Age*).—Abnormal sensibility attended with spasmodic contraction of the vulvo-vaginal orifice often comes under observation as a cause of dysparunia. In such cases the local hyperesthesia is evinced on any attempt at examination, and is most marked about the meatus urinarius or in the vicinity of the vulvo-vaginal glands and fourchette whence the hymen or its remains project upwards.

Without referring here to the different theories which have from time to time prevailed with regard to the general causation of vaginisms, or to the minor cases of this complaint, which are commonly sufficiently relieved by the topical application of methylene blue, cocaine, or other local analagesics, confining myself to the etiology and treatment of those graver forms of vaginismus, occasioning dysparunia, which require more serious remedial measures, I would presume to express my opinion, founded on somewhat extensive experience, that in the great majority of these instances the complaint is not only very intimately connected with the constitutional neurotic temperament generally evinced by such patients, but also that, hardly less frequently, it is also largely ascribable to a special local lesion, viz.: an abnormal condition, or neuritis, affecting the trunk or terminal fibrillæ of the punic nerve, one branch of which supplies the structures in the vicinity of the clitoris, whilst the other, or superficial perineal nerve, is distributed to the labia as well as to the perineum in which its terminal branches ramify.

Strychnia in Uterine Hemorrhage.

Strychnia is now considered a specific in uterine hemorrhage. It should be administered in one-sixtieth grain doses three times a day for a period of from four to six weeks before the time of labor, in all cases where there is a history of flooding. It will also prove of value where previous labors have been tardy, owing to irregular and feeble uterine contractions.—*N. Y. Med. Times.*

Electricity in Gynecology.

Dr. G. Apostoli, of Paris, the ardent advocate of the use of electricity in gynecology,

thus concludes an elaborate article in the *American Journal of Obstetrics:*

Intrauterine electrotherapy (faradic, galvanic, or sinusoidal) as advocated by me, prudently, rationally, and patiently applied, merits to remain at the head of conservative gynecological therapeutics for the following reasons.

1. Because in most cases it assures a symptomatic relief which often takes the place of cure.

a. Sovereign in its effects on endometritis and the principal functional troubles (amenorrhea, dysmenorrhea or metrorrhagia.)

b. Very efficacious against non-cystic fibromata.

c. Often useful—not always—in non-suppurative periuterine inflammation.

d. Powderless, of itself alone, against cystic collections of all kinds, and suppurating lesions of the pelvis or vicinity.

2. Because in the cases where it is inefficacious its failure to benefit can be made use of (by the attentive and harmless study of its reactions during and after application) to clear up or confirm a doubtful diagnosis, and thus to show the necessity of and hasten a surgical interference delayed or already refused.

3. Because if the immediate symptomatic results of its application are generally favorable, the ultimate results offer no less interest by reason of the subsequent pregnancies observed.

Eighty women treated by me, and solely by intrauterine electrical applications, have had, mainly, after a variable delay, but most often after the end of treatment, one or more consecutive pregnancies, which at once testifies to the symptomatic and functional efficiency of the treatment.

In conclusion, I maintain that gynecological electrotherapy, far from being hostile to surgery—on the contrary, often pointing out the way and showing the legitimacy of its indications—claims an important role, whether it be, as in many cases, to avoid a dangerous and useless mutilation; or, as in others, to emphasize the necessity of operative interference; or, in fine, in certain cases to complete the work of surgery which has exhausted its means, and rid in the most efficacious and prompt manner in the complete relief of symptoms and restoration of functions.

Ovarian and Tubal Diseases in the Causation of Sterility.

Ashby concludes a paper as follows: The adjustment of the tube and ovary during ovulation is effected in the human female by the most delicate mechanical arrangement, and may be defeated by trivial mechanical interferences.

In animals that habitually have multiple pregnancies a more perfect mechanical provision is made for the reception of the ovum by the tube. The number of ova impregnated seems to bear a close relation to the perfection of the arrangement which is provided for their passage into the tube. Thus in the bird will be found the most perfect type of mechanical adjustment, in women the most intricate and difficult.

The adjustment of the pavilion of the tube to the ovary may be set aside by the most trivial vices of structure and disease, resulting in absolute or relative sterility.

Sterility is due to minor diseases of tubes and ovaries to a greater extent than has been recognized. In an investigation of the etiology of this condition this fact should be considered in connection with an investigation of other causative influences.

The highest aim of surgery is to restore and not to destroy function. In the treatment of minor forms of ovarian and tubal disease this fact should be borne in mind. Organs should not be sacrificed to the rule of expediency, but should be preserved in deference to a law of genuine conservatism.—*The Am. Jour. of Obstetrics.*

Condition of the Bowel and Contents of the Sac in Strangulated Hernia.

Tietze reports as follows from observations in Mickulicz's clinic and from experiments on animals:

1. Bacteria may be present in the fluid at a time before structural alterations have occurred in the bowel wall where, at all events clinically, the bowel would be spoken of as above suspicion.

2. But this condition is not constant, and the bacteria are not present in such numbers as to modify our treatment. Clinically the fluid is to be regarded as sterile at this stage.

3. Not even in every case of gangrene of the bowel does the fluid contain living organism capable of development.

4. Against certain forms of bacteria the fluid of the sac, both in man and other animals, possess a destructive influence.—*Langenbeck's Archiv.*

Movable Kidney.

The author, Johnson, of Richmond, Va., (*Annals of Surgery*), reports seventeen cases of movable kidney, treated by operation. All of the cases recovered, and nearly all were traced to final results.

In no case was relapse noted, and marked improvement in general health was observed in most of the cases.

The technique employed was, in brief, as follows:

An external incision, beginning half an inch below the twelfth rib and extending downward and outward nearly to the crest of the ilium. The kidney is placed as nearly as possible in its normal position. The capsule is cut through and the edges reflected. A medium sized suture is then passed through the substance of the kidney itself, and the deep portions of the cut abdominal walls, but not ligated until later. The edges of the capsule are then sutured with fine silk to the deeper parts of the wound. The first and larger suture is then tied. The upper part of the external wound is then closed and the lower part packed with gauze The patients, as a rule, are kept in bed four weeks.

The Microbes of the Eye.

The researches of bacteriologists have shown that the conjunctival sac is a famous feeding-ground for microbes of all kinds. A very complete and learned review of the question by Dr. A. Guenod (*Gazette des Hopitaux*), shows the present status of the subject and indicates that, in time, all inflammatory conditions of the conjunctiva will be distinguished nosologically by their specific microbes rather than by the vascular reactions. Thus he shows that the acute catarrhal inflammations are due sometimes to the bacillus of Weeks and, more rarely, to a pneumococcus or streptococcus organism. The purulent conjunctivitis of genital origin is usually due to the gonococcus. Croupous conjunctivitis may be due to the bacillus of Loeffler, but is oftener a mixed infection.

In chronic inflammatory conditions there have been found the trachoma coccus (Koch, Poncet, Michel), the gonococcus, and a microsporon described by Noisewski. In xerosis, the bacillus of pseudo diphtheria is present. The bacilli of tuberculosis and of lupus also may develop in the conjunctiva.

According to Guenod, in the healthy conjunctival sac one never finds the microbes characteristic of the three principal forms of acute conjunctival inflammation (blenorrhagic, diphtheritic, and contagious catarrhal). Only exceptionally does one meet with staphylococci, streptococci, and pneumococci. The conjunctiva is, therefore, reasonably aseptic in healthy eyes. The constant flow of lachrymal fluid across its surface is believed to have some antiseptic influence.

Irrigation of the Naso-Pharyngeal Cavity in Infectious Diseases.

According to this author's experience, Dr. A. Heller, (*Sem. Med.*) irrigation of the naso-pharynx is an excellent therapeutic measure in infectious diseases, being usually followed by a more or less rapid diminution of the fever and other morbid symptoms, shortening the duration of the affection and preventing the production of diverse complications. He employs this "pharyngotherapy" (as he styles it) on the hypothesis that infectious diseases (except cholera and dysentery) are due to the inhalation of the infectious agent, which first localizes in the nose and pharynx, where it multiplies during the period of incubation. The virus penetrates thence into the blood and chyle of the organism, and the infection becomes general.

The author uses boiled water, tepid or warm, pure or with the addition of a small quantity of some saline antiseptic. The temperature of the liquid varies according to the sensitiveness of the subject, the degree of fever and the season of the year. Many patients bear well irrigations of water of as high a temperature as 50° C. These irrigations ought to be made by the physician himself; pressure should be feeble, the current being directed horizontally through the nares, the patient holding his mouth open, lest the injected liquid penetrate into the Eustachian tube. It suffices to inject through each nostril the contents of two or three pear-shaped syringe-balls twice a day.

This treatment it is reported, often immediately produces a considerable depression of temperature, affording marked relief. And, besides, it promptly improves the local lesions of the naso-pharynx, such as anginas of diverse natures.

The therapeutic action of these irrigations, it is said, is especially striking in erysipelas, which often promptly becomes benign and soon disappears. In diphtheria and croup, it peculiarly facilitates the throwing off of false membranes, and frequently arrests the symptoms due to septic infection.

In whooping-cough it removes the viscous mucosities from the posterior nares and the larynx, diminishes the number of paroxysms, and manifestly shortens the duration of the affection. In typhoid fever, these irrigations contribute greatly to moderation of the fever and cephalalgia, to dissipate the delirium and comatose condition, and to restore to the tongue its natural humidity. Finally, they are said to be equally useful in acute articular rheumatism (when the pharynx frequently constitutes the entrance to infection), in small-pox, measles, scarlet fever, tuberculosis of the respiratory passages, and in swelling of the glands of the neck in children.

Heart Disease.

Pawinski (*Therapeutische Monatscheft*) compares caffein natrio-salicylate with strophanthus and digitalis as follows:

In valvular diseases of the heart, with disturbance of compensation, digitalis and strophanthus are superior to caffein, but the latter can often do good service when the former are contraindicated.

In respect to regulating the heart rhythm, caffein is also inferior to the others; but in respect to excitation of diuresis, it is much superior. The best field for the administration of caffein is in diseases of the heart muscle, either functional or degenerative, and especially in the early stages of the disease. But in the later stages, when the heart, in consequence of progressive degeneration of the muscle fibers, is not able to perform its duty, and there are œdema, dyspnœa, and dilatation, then we must resort to digitalis.

Caffein is also indicated in acute insufficiency in patients whose circulatory system is otherwise healthy, such as after severe mental strain, moral commotion, and especially during fevers. In many cases also caffein produces a pleasant narcotic effect.

Lycetol—Antiarthritic.

Lycetol is the tartrate of dimethylpiperazine and appears to be fully as effective as the base Piperazine. Aside from the pronounced action of the latter as a uric acid solvent a favorable therapeutic effect can be anticipated from this preparation because its other component consists of tartaric acid which in the system becomes converted into

a carbonate and renders the blood more alkaline, besides exerting a diuretic influence. According to the theory accepted by many physicians as to the nature of gout, there is no increased formation of uric acid in this disease, but the blood of gouty persons is only faintly alkaline and therefore less capable of holding uric acid or the urates in solution. By the administration of this tartrate of a Piperazine derivative, therefore, the combined effects of its components are secured. Lycetol possesses the additional advantages of having an excellent taste and of being non-hygroscopic. Its aqueous solution has an agreeable acid taste and does not excite repugnance when administered for a prolonged period. Dr. Wittzack who has employed Lycetol in a number of cases of the uric acid diathesis with satisfactory results, observed a considerable increase of the secretion of urine after its administration. The remedy was well tolerated without producing any disturbance of the general health, and under its use the gouty symptoms subsided, and recurrences were prevented, and a considerable diminution of urinary gravel occurred. Dose 1.0 Gm. Pro Die.

Infection Processes and Mental Diseaes.

The endeavor to find a specific organism for every disease has even led specialists in nervous troubles to ask if mental disease can be due to a special organism, and Dr. Charles K. Mills in considering this subject in the *American Jonrnal of the Medical Sciences* concludes that:

1. Specific infection must be included among the causes of mental symptoms and diseases which precede, accompany, or follow febrile and other infectious disorders.

2. Much negative evidence can be adduced in favor of acute delirium or acute mania being due to toxemia—such evidence as is afforded by autopsies which reveal neither gross nor histological lesions; and in these cases the toxemia probably overwhelms the patient before the production of meningitis or other disease.

3. Analogies with nervous affections which are known or believed to be of microbic origin—such as multiple neuritis, myelitis and chorea—favor the view that insanities with similar or related phenomena and lesions are also microbic in origin.

4. The evidence afforded by careful bacteriological investigation of cases of acute insanity is thus far meager, and shows that various micro-organisms may induce the same or similar types of mental disease.

5. The mental disorders of pregnancy and the puerperal state are probably, in a considerable proportion of cases, toxemic, without reference primarily to childbirth; but it cannot be regarded as proved that a bacillus of either eclampsia or puerperal mania is the sole cause of these affections.

A New Cure for Hay Fever.

Fuber, of Hamburg, who suffered a great deal from hay fever during last summer, noticed that in winter a coryza was accompanied with hot ears, which regained their normal temperature when the discharge from the nose was established. He tried a reverse order of things on the hay fever, and rubbed his ears until they became red and hot. It is now the third summer he has led an endurable existence. As soon as there is the least amount of fullness in the nose, the ears are noticeably pale. A thorough rubbing of the ears has always succeeded in freeing the nasal mucous membrane from congestion. The rubbing must be thorough and repeated.—*Med. Reporter, Calcutta.*

Prophylaxis of Consumption.

"A few points on the avoidance of the greatest danger to human life," should be the full heading. Consumption destroys more lives than any other cause.

The first point is that the matter which those sick with lung troubles cough up must be temporarily and permanently disposed of in such ways as to avoid all danger from it.

The infectious matter of the expectoration must not be allowed to dry, for it will then fly into the air and be inhaled.

The cuspidor, or other vessel, which receives the sputa, should contain a little water, or preferably a five per cent. solution of carbolic acid (Solution E.) or of Lysol.

Flies should not be allowed to be the carriers of infection; therefore cuspidors and spit cups should have covers in warm weather.

Each cuspidor should be filled with boiling water, when it is to be cleansed, its cover should be re-applied, and it should then be allowed to stand until it is cooled. One reason for prescribing that only a small quantity of water shall be put into the cleansed vessels, is that the boiling water may act as a disinfectant.

Each sick person must, therefore, have two cuspidors—one in use and one undergoing disinfection and the process of cleansing.

The rooms in which consumptive persons dwell or sleep should be furnished in such ways as to minimize the danger of their retaining infection and to permit their cleansing easily and safely. Carpets should not be in use, wooden floors with a few rugs are best; straw matting is permissible. The idea is the avoidance of raising a dust in sweeping. The floor or floor covering should invariably be cleansed by wiping with a damp cloth, never by sweeping with a dry broom.

The one main point in all this is to keep the infectious dust out of the air of dwellings, that it may not be inhaled.

AUSCULTATORY PERCUSSION AND ALLIED METHODS OF PHYSICAL DIAGNOSIS.*

A. L. BENEDICT, A.M., M.D., BUFFALO, N. Y.

The value of acoustics in the investigation of the viscera is such that the term "Physical Diagnosis," without qualification, is usually understood to refer to methods in which, by the senses of touch and hearing, cognizance is taken of the vibrations of the various internal organs. It is important to note that we have to deal with sounds produced in at least three different ways:

1. Localized vibrations due to the friction of a fluid.

2. Localized vibrations produced by the mutual friction of solid tissues.

3. Resonant vibrations, by the thrill of some anatomical or pathological unit.

Under the first head, may be considered the auscultation of breath-sounds, of the circulatory organs (including the heart, both fœtal and adult, the umbilical, uterine and other large arteries, the cervical and other veins, the thyroid body, aneurysms, the cerebral pulse), of the gastro-intestinal tract (with special reference to direct and regurgitant murmurs at the cardia), and, theoretically, at least, of the superficial urinary organs. It is possible that urethral stricture might be located by the stethoscope and that, in certain lesions of the renal pelvis when the relative flow of pus or urine through the ureters is of diagnostic importance, a special instrument for vaginal auscultation may prove to have a practical value.

Frictions of the second class occur normally only from the movements of the fœtus in utero. They are heard under more or less abnormal conditions in joints, at the line of fracture of bones, sometimes in tendon-sheathes—a case might be cited in which the long tendon of the biceps was involved—and in the true serous sacs, especially the pericardium and the pleuræ.

Widely different in principle from these local frictions, is the resonant thrill of an organ. The so-called muscular quality of the heart-sounds is due to such a vibration but, manifestly, it cannot be separated in practice from the tap of the valve-leaflets. Three methods are commonly used in the investigation of resonance; auscultation of voice sounds, in which we judge of the condition of the lung and pleura by the conduction of vibrations to the surface, percussion and palpation, by which last we seek to appreciate acoustic vibrations vicariously by the sense of touch. In ordinary percussion, also, tactile sensation is, with many persons, an aid to the appreciation of resonance. While the tyro or the clinician in his demonstrations to a class, aims merely to produce a sound and may prefer an artificial plexor and pleximeter, an experienced diagnostician,

*Being the Merritt H. Cash Prize Essay of the Medical Society of the State of New York, 1895.

making an examination for his own benefit, almost invariably uses his fingers and depends largely on tactile perception of the vibrations produced. Much may be learned in this way from a perfectly silent percussion.

It has been implied that sounds produced by throwing an organ into vibration are heard over the whole organ. This is true providing all parts of the organ have the same consistency, as in health, but in disease, some part of an organ may become so altered as to vibrate quite differently from the normal structures. Thus, in lobar pneumonia there is commonly dullness amounting sometimes to flatness, in the lower lobe of the right lung. The writer remembers a case of moderately severe catarrhal pneumonia, in which a zone of infiltration in the middle of the left lung posteriorly, was so sharply defined from resonant lung above and below as to suggest the possibility of a trilobate division. The significance of the words "anatomical or pathological unit" is now apparent. Except in the case of the lungs, disease rarely affects an organ in such a way as to cause one portion to vibrate differently from another; hence in the investigation of the heart, liver, spleen, stomach, intestine and bladder we expect to gain only such information as depends on the question of size—or, in the case of the hollow organs, fullness. A solid tumor of the stomach or bowel affords a marked contrast to the normal tympany, but only when of such size and location as to be quite readily palpable.

The ordinary observer, in the use of percussion, recognizes two degrees of resonance—pulmonary and gastro-intestinal or tympanitic; and two degrees of flatness, absolute flatness and dullness. Nicer discrimination may be made by an acute ear, as in the diagnosis of pulmonary cavities. The gastric tympany is usually about a semitone lower in pitch than that of the colon, while the tympany of the small intestine is still higher; pitch in general varying inversely as the calibre of the resonant body.

By ordinary percussion no distinction can be made between the resonance of the two lungs; hepatic, splenic and cardiac dullness are alike and, practically, it is usually impossible to mark the exact boundaries of the heart and the liver where they approach. Moreover, the overlapping of organs obscures diagnosis and, in particular, the right border of the heart cannot be defined by percussion except by an expert; while distended intestine may lead to the erroneous conclusion that the liver is contracted and splenic dullness may be altogether concealed.

The object of this paper is to call attention to methods of physical examination with which the majority of the profession are unfamiliar, and, for part of which, some originality is claimed. These methods all depend upon the same principle—the setting up of vibrations in an organ and, by excluding indirect conduction of sound, locating the boundaries of the organ by auscultation of its resonance. Perhaps a homely comparison will enable us better to appreciate the problem and the means of solution. Suppose one wishes to trace a system of pipes through a building. If the pipes are of different sizes or if they convey different fluids, for instance gas and water, ordinary percussion will elicit notes of so different quality that the matter is easy. If, however, the pipes are of the same size and filled with gas, no amount of percussion will afford an idea of their continuity unless we listen first at one pipe and then at another and note that, in one case, the sound of tapping is conducted directly to the ear while in another only a diffused noise is heard.

In the case of structures so close together as the viscera, we must limit the conductivity by some form of aural transmitter—of which the stethoscope is the commonest example—and it is this aid to percussion that has given rise to the term auscultatory percussion. The term is objectionable since *auscultatory* by no means implies the use of an instrument. Stethoscopic percussion would be a preferable term, although the language critic might object that a stethoscope is literally a *chest-looker*, while its use is not confined to the chest and it is only metaphorically a *looker*. Not to quibble over a question of nomenclature, it must be recognized that auscultatory or stethoscopic percussion is not merely ordinary percussion aided by an instrument. Ordinary percussion seeks to elicit a characteristic note whose pitch and quality shall enable us to distinguish one anatomical or pathological unit from another of different structure. In auscultatory percussion, on the other hand, almost no attention is paid

either to pitch or quality. We simply endeavor to locate the boundaries of an organ by noting when the sound of percussion becomes suddenly feeble. So long as both plexor and stethoscope are over the same organ, the sound conveyed to the ear is peculiarly sharp and penetrating. As soon as either passes the limits of the organ, the sound becomes dull and diffused. It makes no difference in tracing the pipes through a house, whether the listener is in the attic and the percussor in the cellar or vice-versa. Analogously, it matters not whether the stethoscope is moved or the tapping finger, except that, for the sake of convenience, the instrument is usually held stationary at about the center of the area to be defined. The exact point of application is not important, except that it should be somewhere within the area in which the organ to be investigated is in contact with the body-wall. These areas are easily found by ordinary percussion and they are described or illustrated in most anatomies and works on physical diagnosis. The best example of the radical difference between ordinary and auscultatory percussion is to be found in the examination of the lungs. The former method reveals no partition into two organs, except where the mediastinum widens out; the latter method draws the line as closely as nature herself.

The demonstrable (not the anatomical) cardiac area, as usually taught, is limited by the third rib, the nipple line and the right border of the sternum. The lower portion of the right boundary is obtained by drawing an imaginary line to the palpable apex. The examination to obtain these limits involves almost painfully hard percussion in order to strike below the superficial pulmonary resonance; it is, moreover, tedious and many physicians are unable to find the right limit of the heart. By auscultatory percussion almost the whole cardiac area may be mapped out, and it is nearly as easy to diagnose distension of the right side as outward enlarge ment of the left ventricle.

A graphic representation is not so important in the case of the thoracic organs as in that of the stomach and liver, since changes in the former are easily located by bony land-marks. Moreover, the diagnosis of pulmonary and cardiac disease does not depend so largely upon the determination of areas as it does in the case of the stomach and liver.

The spleen varies in size, even physiologically and temporarily. Some go so far as to say that the normal spleen is not percussible; others, while admitting that it has a definite area of dullness, confess that in many instances they can not locate it. From its position at the side of the body where the ribs have their greatest convexity and from its lack of definite shape, the graphic representation of the spleen on a plane surface is not especially important, yet an approximate estimation of its size is often of the highest value. Malaria, leucocythæmia, malignant lymphoma (Hodgkin's disease), carcinoma, almost all septic conditions of the intestine, various interferences with the portal circulation, infectious fevers, even without intestinal lesion, are among the causes of splenic enlargement. While in many such cases the finding of a large spleen is simply a verification of a diagnosis already well established, in other cases the condition of the spleen is of great importance. Those cases of hepatic cirrhosis without demonstrable change in the liver itself, are among the most puzzling which confront the physician, and the fact of splenic enlargement, not otherwise explained, throws light on the hepatic condition. Again, a case of deep tumor in the region of the left kidney may be cited. With splenic enlargement, some implication of the intestine or, possibly, carcinoma would be thought of. The spleen being of normal size, both these conditions were excluded and the probable diagnosis was made of renal sarcoma which is not prone to anastomosis. The diagnosis was confirmed by hæmaturia. Such cases illustrate the benefit of ausculatory percussion as a far more delicate means of investigation than ordinary percussion or palpation.

It is rather difficult to state exactly what the area of the stomach should be. It varies greatly within normal limits according to the time after eating and the amount of gas produced during digestion, while authorities differ as to its location when distended. Moreover, we can not expect to map out the most deeply seated parts of the organ, any more than to locate the summit of the dome of the liver, which rises at least a rib higher than even the heaviest percussion indicates. The

usual limits of the area of gastric resonance may be assigned as follows. A vertical line extending for an inch or more about the mid-point between the xiphoid and the umbilicus marks the right limit, although the organ itself extends further and a slight transgression of the resonant area is not sufficient to establish the diagnosis of dilatation. The lowest point of the stomach is about an inch, or an inch and a half above the level of the umbilicus and about half way between the median and the axillary line. The left curve varies greatly according to the degree of distension. The anatomies usually picture a thoroughly distended stomach whose extreme left limit is at the level of the seventh rib, touching the thoracic wall laterally, while the highest point of the curve is just inside the nipple in the fourth intercostal space. On percussion, these limits are seldom or never reached. Usually, in a stomach distended as much as possible without spontaneous relief of pressure through the œsophagus, the highest and extreme left points coincide, falling on the sixth or seventh rib and as far to the left as the thickness of the thoracic wall will allow. From this point, there is a sag downward and to the right. One would get the impression from the percussion area, that the cardiac opening of the stomach was at the highest left point; on the contrary, it is located posteriorly and only slightly to the left of the median line. The sag from the highest point, therefore, corresponds not only to the anatomical lesser curvature, but also to the upper part of the greater curvature. Owing to the different degrees of distention of the stomach, to the manner in which it touches the abdominal wall, to the weighing down of the lower part with food or liquid, and to the muscular tone which naturally tends to keep the organ somewhat contracted, the percussion area varies very greatly and it may be considered normal if it falls within the extreme limits mentioned.

The direction of the axis of the stomach is a matter of some dispute. Quain's anatomy represents a distended stomach whose axis is about 55° from horizontal. Luschka figures a stomach inclined at about 45° and passing an inch or more to the right of the median line. At autopsies a marked variation is seen. Since the term gastroptosis was first used, some controversy has arisen as to the normal direction of the stomach, some claiming that the axis of the organ is nearly horizontal, others that it deviates only 20° or 30° from the vertical. Speaking with a limited experience, the writer believes that, in short persons, the axis of the area of gastric resonance is considerably less than 45° from the horizontal, while tall, long-chested persons have a gastric axis with an inclination of 45° or more. This statement applies to clinical appearances and not to the findings at autopsies. It is uncommon to find a stomach that reaches more than a quarter of an inch to the right of the median line, while, without any marked dilatation, the greater curvature may sag as low as the umbilicus. This is especially true of flabby, atonic women who compress the waist with corsets. The whole question reminds one of the controversy among gynæcologists as to the normal position of the uterus. Certainly, the physiological deviations of a soft organ like the stomach are much greater than those of the small and rigid uterus.

The writer would like to call attention to a fact to which most text-books do not allude, namely, that the greater curvature of the stomach, as mapped out by percussion, is, in most instances not a simple convexity, there being usually a slight concavity in the middle of the curve, marking a tendency to the division of the organ into two digestive compartments.

The area of liver dullness begins, on deep percussion, at the fourth rib. The nipple is usually at this level but, not very rarely, it varies on one or both sides, even in men. In women with pendulous breasts it has no value as a land-mark. As the lung substance intervening between the liver and the chest-wall becomes thinner, dullness increases, until at the sixth rib in the nipple line, there is almost absolute flatness. The liver extends to the costal arch. Palpation usually reveals the left lobe of the liver in the epigastrium, but ordinary percussion and palpation afford only the vaguest notion of the contour of the organ. By auscultatory percussion, on the other hand, it is possible, in most cases, to map out practically the whole liver, and overlapping intestine does not materially obscure the findings, whereas with ordinary percussion, it may lead to a diagnosis of contracted liver.

When we remember that the physical

diagnosis of liver troubles depends almost entirely upon the determination of "back pressure" of blood, lymph and bile, and of the size of the organ, the value of even the slightest increase in our means of examination becomes apparent. The writer recalls a patient who had no ascites nor œdema, no hæmorrhoids nor other prominent veins, no jaundice and, for the time being, no disturbance of digestion, yet his liver was scarcely two inches in vertical diameter. Much doubt was felt as to whether the apparent contraction of the liver was not due, at least in part, to distended intestine in the right hypochondrium. Auscultatory percussion would have settled the question at one examination; without it, a positive diagnosis was not made except after several examinations and after securing some significant history.

By auscultatory percussion, the colon can be quite accurately distinguished from stomach and small intestine. The extreme length and complicated coiling of the small intestine prevent its resounding as an anatomical unit, so that auscultatory percussion is, in this case, of little value.

The examination of the pregnant uterus and of various large tumors of the pelvic organs is greatly facilitated by auscultatory percussion. It would seem that one with a gynæcological practice, might so perfect the art of external diagnosis that cœliotomies would not reveal so many totally unexpected conditions of the pelvic interior.

Under ordinary circumstances, it would seem presumptuous to present an essay dealing largely with the general principles of a branch of medical art publicly reported more than half a century ago. Yet, unless recently, the majority of graduates in medicine have left college totally uninstructed in auscultatory percussion, and comparatively few physicians make practical use of it. Thus, one who wishes to become expert, must, as a rule, depend upon his own exertions, aided only by general directions to be found in a few text-books and some articles on this neglected method buried in files of medical magazines. Under these circumstances, some explicit details of the technique of auscultatory percussion may be allowable. While the early authorities recommended a hard-wood monaural stethoscope, the writer believes that any form may be used, and that the binaural instrument is preferable, since it shuts out more completely extraneous sounds. No pleximeter is necessary, thus the physician, holding the stethoscope in one hand and tapping with a finger of the other, needs no assistant. The writer uses for all purposes a Camman chest-piece to which are fitted flexible rubber tubes terminating in hard rubber ear-pieces. This instrument has only two advantages over the ordinary Camman stethoscope; it is portable and, since the ear-pieces must be made to fit tightly into the meatus, it cannot usually be of service to any but the owner, so that the transmission of cerumen from one person to another is avoided. It is a physiological fact that a person accustomed to listening with both ears refers sounds heard with only one ear to the ear itself and thus, there being no distraction of attention to note the direction of the sound, its pitch is a little more sharply defined. Accordingly, the writer has devised a flexible monaural stethoscope which answers the purpose well if the opposite ear is stopped.

The writer would also report the following original methods of investigating visceral resonance. All are used in connection with a stethoscope and no new principles are involved. All are solutions, more or less perfect, of the problem to substitute for percussion a more convenient method of exciting visceral vibrations:

1. Instead of tapping, friction may be used to originate vibrations. The rubber tip of a pencil answers well, or even the end of a dermograph. The choice between friction and percussion depends largely on the sensations of the patient.

2. A tuning fork fitted into a hard rubber handle, is set into vibration and closely applied to the body wall. This method causes neither tenderness nor tickling, as percussion and friction, respectively, sometimes do, while it is even more delicate as a test. (See Chart 4).

3. The tuning fork has the disadvantage of vibrating only for a short time and the repeated snapping of the tines is rather tedious. In order to obtain a continuance of the vibration, a portable Faradic coil has been prepared, the hollow core serving to conduct the vibrations of sound to the body. Within certain limits, it is possible to guage the pitch of the hum-

ming note and, thus, to set up vibrations best adapted to the transmission of each particular organ. It will be understood that the coil is not used as an electrical instrument, the secondary wires being cut short.

On account of the trouble of carrying a battery and of keeping one in order, the writer has found the finger and the tuning fork to be the most convenient means of instituting resonant vibrations.

Contrary to what might be expected, the nature of the body-wall has very little influence on the conduction of vibrations. Thus, in moving the source of vibration —percussing finger, pencil, tuning fork or coil—along a rib, the sound diminishes when the limits of the organ are passed quite as suddenly as if the examination were made over the soft abdominal wall. So too, in passing from rib to intercostal space, the conductivity of the underlying organ is not affected. Although the deepest portions of organs can not be outlined, parts may be mapped that are certainly overlain to a moderate dephth by other viscera.

It is usually advisable to mark the limits of an organ with a dermograph. Tracings may then be made to preserve a record of the case. Photography would naturally suggest itself as a means of reproducing the outlines in their relation to superficial landmarks, but it is impracticable to have the necessary apparatus and assistants always at hand; many patients would object; the expense must be considered; and, most important of all, the lateral regions of the body would appear so foreshortened in a photograph as to give false notions of the actual areas, and it would be difficult to focus either to a life-size or to a uniform scale of reduction. The accompanying photograph is practically, a failure. The patients were boys about twelve years old, presenting symptoms of cardiac hypertrophy. Auscultatory percussion demonstrated that the condition was a neurosis, the cardiac area not being in the least enlarged.

THE TREATMENT OF DIPHTHERIA.

F. R. MILLARD, M.D., San Diego, Cal.

The treatment of diphtheria by antitoxine may be the treatment of the future, but it will be a long time before the remote country doctor can always get the remedy when needed; meanwhile he must use what he can get.

Although no longer in active practice, I would like to recall attention to a plan of treatment which I made known in 1862, and which then raised a perfect cyclone of denunciation. One medical editor kindly hoped I would never get another diphtheria patient to treat; but if I did and it proved fatal, as was certain to be the case, I would be prosecuted, and he would cheerfully testify that I was guilty of murder. I did get a good many cases within the year, and when, in 1863, I made known the number of cases treated and the number of recoveries, old Professor D—— remarked, "Young man, it is evident you don't know diphtheria when you see it." Then I thought the old Nestor rather hard. But since we have imported the malignant bacillus, the benignant bacillus and that other little joker which breeds either way, or both ways, according to its own sweet will, I wonder if he always knows.

I saw diphtheria for the first time in 1858, and every case I had, saw or heard of, was fatal. Still I had learned something—mostly what not to do. In 1859, a case occurred close to my office, and having more time to dispose of than anything else, most of it was passed with my patient; and for her age (six years), she was an ideal patient. I had the satisfaction of seeing her convalescent, and thinking I had learned a great deal. I soon found that I knew more than I wanted to know—I had diphtheria myself. I called in my old preceptor and by his advice, treated the case on the same lines as the preceeding one. Believing it a local disease, and that the general system was

poisoned by absorption, I reasoned that three things should be attempted: prevent or limit absorption from the throat (belladonna); neutralize the poison at its place of origin (protiodide of mercury); eliminate it from the system (calomel).

Saturated solution Potass. chlorat.... q. s

Sig. Wash the mouth and throat with the solution, and then swallow a teaspoonful just before each dose of medicine.

Protiodide of mercury..... gr. s iij
Powdered white sugar..... ʒ iij

M. and divide into 24 powders.

Sig. One powder every 2 hours. Place in the mouth dry, and swallow slowly as dissolved. Allow no food nor drink under 15 minutes after taking.

Calomel ..... gr. s xxjv
Ext belladonnæ..... ... gr. s vj

M., and ft. pil. 48.

Sig. Two pills every 2 hours, alternating with powders, until the bowel has moved twice; after which one pill at a dose. Omit occasionally if the bowel moves too often.

Continue this treatment until the throat is free from false membrane, and then give quinine and tincture of iron.

There is another drug of which I have always made much use, and which has prevented me having much experience with post-diphtheritic paralysis. Strychnine, given early and freely, will almost always prevent its occurrence. Alcohol is often recommended for its action on the heart. Belladonna is far preferable, but strychnine is the thing to tie to every time. Never give alcohol. It is an anesthetic to the higher nerve centers, whose sole superiority to other anesthetics consists in its more prolonged action. It is given, also, to retard tissue change. Now, in poison from snake-bite, if tissue change can be delayed a few hours the poison is eliminated and the patient recovers. If strychnine cannot be given hypodermically, alcohol is of use. If strychnine can be so given, it is infinitely better. But the elimination of the diphtheritic poison is not a question of a few hours, but of many days. I do not expect to live to see alcohol religiously excluded from use in diphtheria, but some of the young men now in the profession will see it.

I wish here to call attention to the *diphtheritic pulse.* It is almost, if not quite as characteristic of the disease as is the eruption of scarlet fever. Probably all who have treated diphtheria know the pulse of the later stage, which is caused by granulo-fatty degeneration of the heart muscle. But I refer to the pulse in the early stage, which is caused by the poison acting on the nerve centers, and if carefully compared, the pulses will be found quite different. A little consideration will show that this is necessarily so. As the disease progresses the original cause is still acting with a constantly increasing power, and in the later stage this is complicated with the action of a degenerated heart muscle. I do not know whether this pulse can always be detected before the appearance of the false membrane, or not. Most of my knowledge of the disease was acquired in country practice, where one is seldom called until the membrane can be seen. It was my practice when treating a case, to examine the throat and pulse of each member of the family daily, or oftener if possible, and I have found it twelve to twenty-four hours before the appearance of the membrane—occasionally in persons who claimed to feel perfectly well. During the later years of my practice, when I found a member of a family with this pulse, he was put on the diphtheria treatment, and often no membrane would form. In two or three days the pulse would lose its diphtheritic character and return to the normal, thereby proving to my satisfaction that it was caused by the poison acting on the nerve centers.

It is true that if alcohol is given when the heart is first affected, it apparently is of benefit. The pulse becomes lower and fuller, the surface cooler and the patient brighter. But this cooling, consequent upon the dilation of the cutaneous capillaries, must be made up by an increased expenditure of vital force. As alcohol retards the elimination of the poison, it is deleterious. The most convincing argument I can conceive for its use in the late stage is that, "the hair of the dog ought to be good for his bite." I have long and firmly believed that a large proportion of the diseased kidneys found by European observers at autopsies on those dead of diphtheria, was caused by alcohol.

It is well known that in this last stage, children bear a large amount of alcohol without intoxication, and some report with apparent satisfaction the quantities prescribed. In one case, "8 f ʒ of good brandy in twenty-four hours, to an eighteen months' old baby." At last accounts, the doctor was still cogitating whether that "good critter of God," *good old brandy,* could have had anything to do with the baby's death.

Thirty-six years are passed and I still

have a vivid recollection of the increased discomfort, and as I thought aggravation of symptoms, produced by cow's milk, when fighting diphtheria in my own person. So I never used it if it were possible to feed the patient on anything else. Keep him as near as possible on his usual ration of solid foods.

In treating many diseases it is not well to waken a sleeping patient to give medicine, but in this disease, until the throat is clean or rapidly clearing, it should be done if necessary; for the frequent repetition of the dose is of prime importance.

Of the hundreds of cases treated on this plan not one was salivated, nor did a case of kidney disease develop. If albumen appeared in the urine it was disregarded and soon disappeared without special treatment. I induced a few of my medical friends to adopt this plan, and none of them ever relinquished it except with life. True, like myself, they would try some so called scientific plan, and like me come to grief and return to the old plan. When the "bichloride" treatment became fashionable I took it up with a good deal of confidence and for a time was well pleased with it. True, my cases got well no quicker than usual, but they did well and it was scientific. At length diphtheria attacked a family of seven persons. Five of them yielded to the bichloride treatment, and two (a child of two years and its mother) seemed in a fair way to soon yield to the undertaker. The bichloride was stopped and they were subjected to my tried formulæ. In less than thirty-six hours no membrane was to be seen in either throat. That was my last experiment with new modes of treating diphtheria.

It was my custom to use chlorate of potash and tincture of iron as a prophylactic. As soon as a case occurred, the entire family used the gargle and took the iron and potash in sufficient water. It often happened that when diphtheria attacked one of several children living in a miner's cabin of one or two rooms, the thermometer constantly below zero, no other case would develop in that family.

It is, perhaps, needless to say that the dose of belladonna may require reduction; but it should be given in doses as large as can be born. If fed on solid food, most patients can take the protiodide in he doses recommended. If trouble occurs it often can be overcome by giving a little of the home-made extract of beef a few minutes before the medicine. When made in the old-fashioned way, by boiling the finely-cut beef in a tightly-corked bottle, it is for this purpose superior to any of the proprietary, trade-marked extracts. When preparing the powders for children, it is well to increase the proportion of sugar somewhat, as the protiodide is thus more certain to reach every part of the throat.

The test of a successful treatment can not be made by a few cases, nor in one or two years. From 1862 to 1867, not a single case that was treated on this plan for twenty-four hours with even a fair degree of regularity, was fatal. I felt a good deal like bragging, but determined to wait until 1869, which would give a trial of ten years. The fatalities of 1868 took all the conceit out of me. Yet, as I look back and find a mortality of less than 17 per cent. for that year, and take into consideration the ignorance and filth of a majority of the fatal cases, I do not think it a record of which one need be ashamed.

Migrain.

Migrain, according to Dr. J. H. Kellogg, in *Modern Medicine*, is due to a high degree of acid fermentation or an excessive quantity of mental chloro-organic compounds. In both conditions the stomach contains a vast quantity of toxic substances, which when absorbed into the blood, induce a veritable toxæmia and utellectual activity, is an exciting cause of the disease, and through the fact that, by a morbid reflex action downard, it increases the hyperæsthetic conditions of the abdominal sympathetic, and at the same time retards the digestion, and so favors both the production of toxines, which are the direct cause of the disease, and the susceptibility of the sympathetic to the action of these poisonous substances.

Viewed from this standpoint, migrain is no longer a complex or mysterious malady, but simply a state of systematic poisoning, the origin of which is decomposition of food products in a dilated or prolapsed stomach, which, through motor insufficiency, is unable to unload itself of its contents with sufficient promptness to prevent septic and putrefying processes.

ACUTE CATARRH OF THE MIDDLE EAR OF AN EPIDEMIC CHARACTER.*

SETH SCOTT BISHOP, M.D.,† CHICAGO, ILL.

This case is typical of a large experience we have had since the fore part of last January, with a certain disease that invades the nose, throat and ear. When you inspect this man's ear you will see a drum-head that presents the characteristic appearances in acute inflammation of the middle ear resulting from the epidemic influenza. These cases differ from the simple acute inflammations that occur in the intervals between the grip epidemics. The drum-head in this case has a peculiar mottled appearance due to extravasation of blood in patches, so that, instead of a turgid condition of the malleal plexus of vessels, a cherry-red color of Schrapnell's membrane, or a diffuse redness extending quite equally over all the membrane, we have ecchymoses in several parts of the drum-head.

The whole membrane is thickened, bulging with muco-serous effusion into the tympanic cavity and has a roughened, leathery appearance. The pain is intense, due to the tension upon the nerves distributed to the drum-head, and to the pressure of the secretions on the sensitive walls of the middle ear. You will observe that the patient winces when I draw upon the auricle to straighten the canal, or when I press upon the mastoid process.

There are symptoms of incipient mastoid periostitis—tenderness, redness and pain, but not, as yet, any appreciable swelling. At this stage the periostitis can be aborted, but we are not so sure that we can prevent suppuration in the middle ear. The probabilities are that we cannot, for middle-ear inflammation, as a complication of the epidemic influenza, is very prone to terminate in suppuration.

This man says he was taken with an attack of the grip five days ago, and that the ear began to pain him two days since. The mastoid pain came on last night, so you see we have an early opportunity to cut short the mastoid trouble. If there was no effusion into the middle ear and consequent bulging of the membrana tympani, we would rely upon warm instillations of twenty per cent. solution of cocaine, and leeching to relieve the pain and inflammation, but the condition present indicates a paracentesis, which I shall proceed to make in the posterior, inferior quadrant of the membrane, so as to give the most perfect drainage.

We will first use the cocaine, which will render the operation much less painful than it otherwise would be. Here we have an animal membrane with an alkaline fluid on one side, of greater density than the aqueous solution on the other, so that by the resulting endosmotic force the cocaine is brought into contact with the inner mucous coat of the drum-head. This fact explains why cocaine is much more effective in producing anæsthesia of the drum membrane in these cases than in those in which the tympanic cavity is in a dry stage of inflammation.

Now that we have opened the membrane, you will see that the discharge is quite copious. It consists of serum thickened with mucous and mixed with blood. Probably the drum-head would have ruptured spontaneously in a day or two if left alone, but we have afforded relief to the patient and insured an opening for the exit of discharges in the most advantageous location for free drainage.

We will use counter-irritation to subdue the mastoid periostitis. The patient will be instructed to apply a mustard plaster to the skin surrounding the auricle, and to keep up a continuous irritation for two

* A clinical lecture delivered at the Post-Graduate Medical School and Hospital of Chicago.

† Professor of Diseases of the Nose, Throat and Ear in the Chicago Summer School of Medicine, etc.

days, but without blistering. We should take pains to give the minutest instructions in all details for home helps in the treatment of these people, otherwise we will not obtain the expected results. The most surprising mistakes occur unless we are patiently explicit in giving directions. For example: A worthy dame was told to procure a half dozen leeches for her husband, who was suffering severely, but through some oversight she was not definitely instructed in the art of applying them. At the following clinic, when asked if the leeches relieved her husband, she astonished the assembly by replying, "Sure doctor, but my man did not like them raw, so I fried them for him."

You will notice that this patient's general condition is bad. When he entered the clinic we observed that his countenence was pale, great drops of sweat stood on his brow, he was weak and shaky, his tongue was covered nearly to the border with a dirty gray fur. It was indented by the teeth, flabby and tremulous. He presented the appearance of a man who had been wrestling with a painful, exhausting disease that was getting the mastery of him; but we can confidently predict that the mastoid inflammation will be subdued within two or three days, and probably the ear will be restored to a good condition within as many weeks. Remember that the cure is not complete when the ear ceases to discharge. It must be treated after all discharges cease until it returns to a healthy condition. This is the point where many physicians and the laity generally commit a grave error. They imagine that the ear needs no care from the instant that they can see no discharge. They discontinue treatment there and abandon a diseased ear to its unhappy fate. Then they marvel that the hearing fails and that each succeeding cold in the head leaves them worse off than they were before.

The general condition of this man needs attention. He is constipated and worn with harassing pain. We will give him a small cathartic dose of calomel to-night and follow it with an effervescing saline laxative in the morning—flush the sewer. We will give him for the pain one-eighth of a grain of morphia combined with one-four-hundredth of a grain of atropia. For loss of strength and appetite he will have two grains of quinine with a tablespoonful of coca wine (Vin Mariani), four times a day. If the quinine produces any subjective noises, sensation of stuffiness in the ears or impaired hearing, it will be discontinued, and strychnine, digitalis and iron substituted.

During the epidemics of influenza I have observed that the aural complications usually appear about the fifth day after the seizure. The pain is intense and exhausting. The effusion of serum occurs sometimes in a few hours after the pain comes on, within twelve or twenty-four hours. In children the first symptom that attracts attention is worrying or crying, pressing the ear against the mother or nurse, or carrying the hand frequently to the ear, followed shortly by a watery and bloody flux from the ear. Usually the discharge commences within forty-eight hours of the beginning of the earache. The proportion of cases in which there is a mastoid involvement is vastly larger than in simple acute otitis media occurring in the intervals between the epidemics. The tendency to suppuration is far greater than in the intervals. The constitutional disturbance is more profound and the disease is less easily controlled. General treatment is quite as important as special. Antipyrine, phenacetine or guaiacol may be indispensable to reduce temperature. Rest should be enjoined and the surface temperature should be kept equable by confining the patient to the bed for a few days. Relapses are more likely than at other seasons, and the patient should not be discharged as cured in less than a week after all symptoms have disappeared.

For home treatment we will instruct this man to syringe his ear, whenever it fills with discharge, with a quart of water as warm as can be comfortably borne, but it must have been previously boiled for a half hour in order to sterilize it. Then he will instill into the ear a warm saturated solution of boracic acid in rose water. Some one suggests that an alcoholic solution be used. I have seen it tried, but I have not the temerity to experiment with alcohol in an acute inflammation of the eye or ear. The solution will be left in the ear while he lies on the opposite side for ten minutes, then allowed to run out and a small piece of absorbent cotton will

be lightly introduced into the mouth of the canal to protect the drum from cold air and foreign matters. For his naso-pharyngeal catarrh he will spray his nose and throat every morning and night with a three per cent. solution of camphor-menthol in lavoline.

The subsequent treatment to be pursued in our clinics to complete the cure will form the topic of another lecture.

ACROMEGALY.

E. L. BULLARD, M.D., WAUKESHA, WIS.

In 1885, during his term as chief assistant to Charcot, Pierre Marie observed in the clinics of the former, two unique cases characterized chiefly by an enormous development of the hands, the feet and the chin. The following year, in the *Revue de Medicine*, he wrote an exhaustive description of these remarkable dystrophies and designated this disease, which had hitherto been unrecognized as a distinct pathological entity though its characteristic symptoms had been noted by Sancerotti as early as 1772, Acromegaly. Von Recklinghausen prefers the name Pachyacria as being etymologically more accurately descriptive; and in accordance with a custom which has the sanction of long usage, this affection has also been named after its discoverer, Marie's Disease. After the attention of the medical world had thus been directed to this interesting malady, other cases were reported by various authors, chiefly European, and up to the present time, according to Osborn, (from whose article in the *Reference Handbook of the Medical Sciences* I have made copious extracts in this paper) about one hundred cases have been recorded. Among this number, however, there were several cases concerning which the diagnosis was not well established, this disease having been confounded, in many instances, with gigantism, myxœdema, exophthalmic goitre, etc.; and, per contra, numerous cases described under the latter heads were undoubtedly true cases of acromegaly.

One who has seen a well-marked case of this disease will never forget it. The subject is bulky and his appearance suggests physical inertia and mental hebetude; he is humpbacked, the movements are slow and cumbersome, and the expression of the face, which is enormously enlarged, is not suggestive of too much intelligence; the forehead is low and retreating, the nose of more than ample proportions, the lower lip thickened and everted, and the lower jaw elongated out of all proportion to the other features, producing a most remarkable physiognomy. The *tout ensemble* suggests a reversion toward the original type of being.

The disease, in the vast majority of instances, is one of adult life, being commonest between the fourth and fifth decades. Two recorded cases have been congenital and two have occurred between the ages of ten and twenty. It affects both sexes in about equal numbers, being slightly more prevalent in females. The onset is insidious and the course pre-eminently chronic. There is diminution of sexual desire which may even reach complete abolition, and in women the menopause is one of the earliest and most frequent symptoms. Cephalalgia, usually referable to the vertex or frontal region, and of ever varying intensity from a slight feeling of discomfort to the most agonizing pain, is a very constant symptom. Pain in the affected joints is also common. Vaso-motor disturbances causing local paleness and flushings, senations of numbness, formication and hyperesthesia of the affected parts are not uncommon. The reflexes are present. The mental faculties are ordinarily unimpaired, but loss of

memory and dullness of perception are not of infrequent occurrence. In some cases there is great somnolency. The enlargement affects alike the bones, the cartilages and the soft parts, and in each instance is a true hypertrophy. The skin is apt to be flabby and of a brownish olive color, particularly about the face. In some patients, together with the subcutaneous tissue it is greatly thickened over the affected parts. Hyperhidrosis, either local or general, is frequent. The hair is coarse and abundant, and is notably increased on the body and extremities.

Taking up *seriatim* the various regions of the body, we find that the bones of the cranium participate but slightly in the enlargement, but there is apt to be some thickening at the sutures, the ridges and protuberances or muscular attachments. The forehead is usually low and retreating, the superciliary ridges prominent from enlargement of the frontal sinuses, the eyebrows heavy. The eyes are prominent, due not only to an enlargement of the eyeballs but also to an abnormal deposition of bone in the orbits. The integument covering the palpebræ is deeply pigmented and their cartilages sometimes enlarged. Progressive loss of sight occurs in more than half the cases, which is due, according to Marie, to pressure upon the optic chiasm by the enlarged pituitary body. It would seem equally as probable that this condition might also be due to bony pressure upon the optic nerves where they emerge through the optic foramen.

The cheek bones are prominent, owing to a dilatation of the antrum of Highmore on either side. The nose is enlarged in all directions and may be prodigious. The upper lip may or may not be enlarged, but the lower lip is enormously thickened, everted and protuberant. The inferior maxilla is massive and while the rami may increase to such an extent as to force outward the lower part of the external ear (which appendage is also usually enlarged), the principal enlargement is in the body of this bone, the alveolar border and symphysis of which are very prominent. Prognathism is marked and is rarely ever absent. The increased growth of the alveolar border is not participated in by the teeth, and they are consequently widely separated and often fall out The angle of junction between the body and rami becomes obtuse as in old age. Owing to the extreme projection of the chin, the facial angle approaches that of the Simian family. The contour of the face is elliptical.

The thorax is greatly enlarged in its antero-posterior diameter and is flattened laterally. Cervico-dorsal kyphosis is rarely ever absent if the disease is sufficiently advanced, and there may be compensatory lordosis. Sometimes, though rarely, scoliosis is observed. Kyphosis is due to a thickening of the bodies of the vertebræ and of the intervertebral substance. The neck is short and thickened and the chin approximates the sternum. The extremities of the clavicles are enlarged. The ribs are wider, thicker and more oblique than normal, and their cartilages are enlarged and more or less ossified. The sternum is widened and thickened, and the xiphoid appendix is unusually prominent.

There is enlargement of the pelvic bones, especially at the pubic symphysis and at the crests of the ilii.

The arm bones are not affected, but the lower ends of the radius and ulna are enlarged. All of the bones and soft parts of the hands are increased in size, and the hypothenar eminence is unusually prominent.

The femur is enlarged at the condyles; the patella is also enlarged. The malleoli are generally increased in size together with all of the bones and soft parts of the foot. The great toe is especially prominent, and the os calcis is enlarged out of proportion to the other pedal bones, giving the heel a decidedly African appearance.

The muscles are generally flaccid, and a condition of progressive weakness is the rule, though in some cases there has been an increase of strength at the beginning. The tongue is uniformly enlarged and the soft palate and uvula may be. Articulation is laborious and the voice guttural. Polyphagia and polydipsia are usual. The bowels are ordinarily constipated. Diabetes and albuminuria are not infrequently associated with this disorder.

The pathology of this disease is not well understood. Marie says that the ganglia and the cord of the sympathetic are enlarged and thickened, and there is frequently enlargement of the hypophysis cerebri, but as the functions of this body

are yet unknown, we are still left in the dark.

It is only in the early stages of this disease that there can be much difficulty in its diagnosis, for, later, characteristic landmarks are so clear that literally "he who runs may read," Marie having diagnosed a case while walking on the streets of Paris. The affections with which it is most liable to be confused are gigantism, myxœdema, leontiasis ossea, the osteitis deformans of Paget, and elephantiasis. In gigantism the extremities are proportionate with the stature, the face is not elongated, prognathism does not exist, and the general symptoms of acromegaly are absent. In myxœdema the soft parts are alone affected and the face, according to Sir William Gull, is "like a full moon." In leontiasis ossea there are bony tumors of the face and cranium, but there is nothing unusual about the hands and feet. In the osteitis deformans of Paget, the cranial bones are enlarged, and if the facial bones are affected it is only in a slight degree; the face is triangular with the base upward, the long bones are principally affected and show a tendency toward abnormal curvatures. It usually occurs after the age of fifty. In acromegaly the facial bones are affected primarily, and if the cranial bones are involved it is to but a slight degree; the face is elliptical; the hands and feet are of unusual size, and the long bones scarcely at all affected. It usually occurs before the age of fifty. Elephantiasis is a disease of the skin and subcutaneous tissues; it seldom affects the face and upper extremities; it is frequently unilateral and the bones are never affected.

The duration of acromegaly is twenty to thirty years or longer, and if the patient is not carried off by some intercurrent affection, death is due to exhaustion.

The treatment should be directed toward the alleviation of the symptoms as they arise.

The foregoing article describes pretty accurately the very typical case which I had the pleasure of presenting to the society by the courtesy of my friend, Dr. J. A. Rice, of Merton, in whose practice it occurred.

The patient, Mrs. F., is an American woman of English parentage; fifty-one years of age; married and has had two children, the youngest of whom is nineteen. The family history is excellent, her father and mother both having attained an old age. She has had seven brothers and four sisters, all of whom, except two, are living and in good health. One sister died of consumption, and a brother of "dropsy." She always had a strong constitution, and up to the time of her last confinement had never been sick. This last labor was protracted and severe, and she dates her trouble from that time. Menstruation never returned, and it was not long before tachycardia, the enlarged thyroid, prominent eyeballs and other symptoms of exophthalmic goitre appeared. Dr. Rice tells me that at no examination during the last fifteen years has the pulse been less than 120 per minute. The enlargement of the hands, feet, nose and chin, began about ten years ago and has steadily increased. Headache has been a prominent symptom.

This case presents the usual well-marked characteristics of acromegaly. The ears, nose, lower lip, tongue, inferior maxilla, hands, feet, clavicles, ribs, sternum, patellæ, and pelvic bones are enlarged. There is prognathism to the extent of about one-half inch. The neck is short and thickened; the thyroid gland is enlarged and cartilaginous, the right side thereof being the larger of the two. There is pulsation in the veins of the neck; cervico-dorsal kyphosis is marked and increasing. Her former weight was 127 pounds; it is now 214. Her height is 5 feet, and the length of the foot (which ordinarily bears the relation to the height of one to six) is 11 inches, or one to five and one-half. There is impairment of sight, but the eyeballs are not as prominent as they were several years ago. The eyes are surrounded by a pigmented areola which varies in intensity. The mental faculties are little, if any, impaired, but the memory is poor. Polyphagia and polydipsia are present. There is hyperhidrosis. Saccharine urine and albuminuria have at times been observed, and there has been considerable edema of the feet at different times. The voice is masculine.

A comparison of a picture representing her present condition with a daguerreotype taken some twenty-five years ago, illustrates better than any description I can give the changes which this disease has wrought.

COMMUNICATIONS.

BACTERIOLOGICAL DIAGNOSIS OF DIPHTHERIA.

E. G. MATSON, M.D., PITTSBURG, PA.

At the present time bacteriology offers practicable methods of diagnosis in three diseases, viz.: pulmonary tuberculosis, diphtheria and cholera. Apart from these the difficulty or duration of the methods, or the slight value of negative results, is a serious practical obstacle. In the case of tuberculosis the diagnosis may be made by any one with a suitable microscope on account of the striking color reaction. In the other two diseases mentioned more laboratory apparatus is required; and these organisms are not readily identified except by persons who have more skill and experience in such matters than will ever be possessed by the average physician. These conditions are met, so far as diphtheria is concerned, by what is generally known all over the world as the American or New York system, by which the health authorities furnish gratuitous bacteriological examination.

What is known as the diphtheria or Klebs-Lœffler bacillus was first described somewhat imperfectly by Klebs in 1883. In 1884 it was re-discovered by Lœffler, the essential results of whose work have remained unchanged by all subsequent investigation. Lœffler showed that it was a pathogenic microbe capable of producing death in animals by infection. On the other hand, he did not venture to consider it the specific cause of diphtheria, mainly because he did not succeed in finding it in all cases examined. On this account it attracted but little attention in the following four years. In 1888 Roux and Yersin made the all-important discovery that the Klebs-Lœffler bacillus, when grown in cultures outside of the body, is capable of producing a poisonous substance which is capable not only of killing animals in very small doses, but also produces paralysis in those which live long enough to acquire it. The complement of this discovery was Sidney Martin's announcement in 1892 of a similar toxic substance which was extracted from the membrane of actual cases.

Zarniko* said that in 1890 the Klebs-Lœffler bacillus had been found in two hundred and forty-nine cases and was absent but twice; while in nearly all cases it had been sought in vain in healthy people.

In 1890 Baginsky began to employ the bacterial diagnosis of diphtheria in the recently-opened pavilion for that disease in the Emperor and Empress Frederick Children's Hospital in Berlin. A similar course was adopted by Roux in Paris at the Enfants Malades. This system has been carried out more or less thoroughly in the hospitals abroad since the last mentioned date, and has also been made use of by private practitioners. Finally the provision made by great cities for the diagnosis of all cases within their limits has enormously extended the range of available experience.

It is evident from this historical sketch that our present knowledge of the Klebs-Lœffler bacillus rests on a very broad basis involving many thousand cases examined in several different years and places, and by many different observers.

That the Klebs-Lœffler bacillus is the specific agent of infection is not universally conceded. As far as known to the writer, the denials come mainly from those who are distinctively pathological anatomists, and who show a very evident disinclination to see the basis of the classification of disease change from the anatomy of the lesions, on which, by virtue of their labors, our present system rests. Indeed, one might say now that bacteriology has reached that material stage of success which is manifested by endowed and subventioned institutions and a hierarchy of teachers from Koch and Pasteur down to propagate it, that the pathological anatomists are rousing from their lethargy and preparing to make one last united charge before it becomes too late.

*Berl. Klin. Wochenschrift. 1892, p. 208.

When Koch laid down his first principle, that the specific ineffective agent must in all cases be found in the characteristic lesions of the disease, he evidently accepted the distinction of the pathological anatomists and clinicians as finalities—at least so far as transmissible diseases are concerned; for if more than one infecting agent can produce like lesions and symptoms; or, on the other hand, if the same infecting agent can produce lesions with different characters in different cases, Koch's first canon would be of slight value in establishing the relation of parasite to disease. It was a fortunate circumstance for bacteriology that the outlines of the various morbid entities were laid down with a great deal of correctness before its birth. Otherwise, to define a disease as the morbid process associated with a given micro-organism, and then to attribute the disease to that organism because it was always found associated with it, would have had very much the appearance of begging the question.

In the early part of this century diseases were simply congeries of symptoms. Dropsy, for example, was regarded as a disease in itself, and not a symptom—or, at least as a consequence of a disease having its actual seat in the heart of the kidney, and the like. The classification on a purely symptomatic basis was necessary at a time when pathological anatomy was unknown. Yet when the pathologists began to distinguish by the difference in the morbid anatomy, what had long been regarded as one disease, many clinicians still refused to accept the new classification. Thus a typhlitis and empyema were regarded as the same disease. Another example is typhus and typhoid fever. As late as 1850, a distinguished clinician of London gave it as his opinion that there was no valid distinction to be made between cases of low fever with intestinal ulceration and those without. The question at issue between the pathological anatomists and the bacteriologists is simply whether all persons having their tissues damaged by the invasion of the same specific infecting agent, no matter what form the damage may assume, are to be considered as having the same disease; or whether only those in which the damage assumes the same anatomical form?

There is but one decisive source of evidence to settle this question which is independent to bacteriological observation. This is the filiation of the successive cases in an epidemic. Epidemiology has shown us the distinctions which have a sound basis even where the morbid anatomy is not decisive. If we can be certain that a catarrhal pharyngitis has caused a diphtheritic angina, we are bound to assume that the two are of the same character, as we are bound to consider parents and their offspring of the same species. The history of epidemics makes the distinctions evident where clinical and anatomical evidence leaves us in the lurch. Thus when influenza is epidemic, who is a sufficiently skilled diagnostician to distinguish between these cases and those suffering from colds and the like? The same thing may be said of cholera nostras and even simple diarrhœa during epidemics of Asiatic cholera. The validity of the distinction between typhus and typhoid fever was largely made evident by the fact that typhus fever was not epidemic in all cities in which typhoid fever was epidemic. We are all familiar with the role played by American physicians who studied these diseases in both London and Paris as well as at home.

In the struggle the clinicians were so completely vanquished by the pathological anatomists that the former have busied themselves with discovering the clinical signs of diseases as classified by pathological research; and, as the result, we are now able to distinguish many forms of disease which were once confused. It is not unnatural, therefore, that the anatomists are disconcerted to find that their victory has only brought them new antagonists; nor is it remarkable that the struggle should be brought to a focus in diphtheria, in which a well marked pathological lesion, owing to its conspicious seat, is itself the most important clinical sign.

While the lesser lights are pugnacious, however, the master himself has very clearly recognized the weakness of a strictly anatomical classification.* Virchow has said plainly that "Etiological unity does not follow from correspondence of anatomical lesions." The same pathological process is found in other mucous membranes as in diphtheritic infection of the pharynx; thus in the rectum, in dysentery; on all

* Berl. Klin. w. 92 p. 281 ff. Berl. Med. Soc.

possible mucous membranes, in cholera, as in the pelvis of the kidney, and in the gall bladder. Pseudo-membranous destruction of the epithelium of the colon may be the result of corrosive sublimate poisoning as well as of dysentery. In each case the lesion is of the same anatomical character as in diphtheria of the air passages. "Now," says Virchow, "since we know that whatever may be the true cause of dysentery it is certain that it is not caused by corrosive sublimate, we are bound to recognize that identical lesions may be produced in the same organ by causes as distinct from each other as corrosive sublimate and the cause of dysentery."

None the less, pathological anatomy is always of importance. A diphtheritic inflammation everywhere means a necrosis of the mucosa to a greater or less depth, whether it be due to the infection of diphtheria, cholera or dysentery, or to poisoning by corrosive sublimate; and in consequence this form of inflammation is followed by an ulcerative process. Again, the locality is of consequence. Thus, as Virchow says, to say that the patient is suffering from corrosive sublimate poisoning is not the same as to say that he has a pseudo-membranous colitis, for he may be free of this and be suffering from a nephritis.

The fact that Klebs-Lœffler bacilli are not always to be found in the false membranes of the air passages does not in the least disprove the claim that it is the specific cause of those in which it is present. Those who attack it on this ground are unconsciously assuming as an axiom, that all diseases of the pharynx in which there is a necrosis of the mucosa with the formation of a false membrane are necessarily due to the same infection. We have just seen that this, so far from being a basis of argument, is a contestable hypothesis which ought first to be proved.

In laying down the principle that the suspected microbes must be constantly found at the site of at least the early lesions of the disease, and absent in normal conditions, it is not to be understood that the mere presence on the tissues and not in them is evidence that they are of innocent character. With due allowance for the incubation and convalescent stages, their presence without lesions shows of course that the same organs in different persons are not susceptible to attack by them. When Koch, after nearly a hundred post-mortems of fatal cholera cases, found that an organism new to him was in the van of all other's in the mucosa of the intestine, he naturally assumed that he had discovered the cause of this disease.

This brings us to the consideration of the fact that the Klebs-Lœffler bacillus is found in healthy throats. If persons not known to have been associated in any way with diphtheria cases are made the subjects of examination, the number in whom this organism is found is really very few. Thus in New York three hundred such examinations were made with only eight positive results, of whom two afterward developed diphtheria. Inasmuch as diseases are generally acquired in trivial acts which do not arrest the attention, and no one in a crowded city where the contagious disease is endemic can actually be certain that he has escaped all possibility of contagion mediate or immediate, these "diphtheria healthy" persons justify no further conclusion than that some persons are insusceptible to the germs.

On the other hand if children who are actually exposed are the subjects of examination, the bacillus is much more commonly present. It is quite probable that if the methods of examination were capable of demonstrating the presence of the germs when they were few in number, and the examinations were made daily, that the percentage in exposed persons who remain well, would be very large. The situation is the same in the case of cholera. Koch has pointed out that this fact does not disprove this specific character of the comma-bacillus because it is never found in healthy persons in regions from which cholera is certainly absent.

It will be of interest to consider whether in accordance with our epidemiological knowledge of diphtheria this fact is what must be expected of the infective agent or not. In the case of measles we do not assume that a child previously attacked, who escapes contagion in a household epidemic, has by chance not really been exposed like the others. On the contrary we say that he is immune to measles because we believe that he has been exposed. Yet no one has been exposed until he has actually received the morbid matter, whatever it may be, and no one can be said to be immune whose tissues have not proved

themselves actually hostile to the invasion by repelling an attack on their surfaces. No one would consider that a microbe was definitely proved not to be the cause of measles because it was found on the mucous surfaces of immune persons. On the other hand those who are most inclined to claim everything for predisposition to an infective disease, are at least inclined to take into account the degree of natural immunity that can actually be shown to exist by other than bacteriological methods.

In measles we find that the malady seizes on nearly every child within reach, and nearly at the same time, except of course those who are immune by virtue of a previous attack. At the close of the incubation period, after the first child has acquired the disease, it breaks out as an explosion among the others. These well-known facts show that there is neither a permanent nor temporary natural immunity to measles except in an exceedingly small fraction of the population. It is almost entirely a question of the transmission of the contagious matter, and very little a question of the condition of the tissues upon which it was received. The future discoverer of the specific germ of measles will be under the necessity of showing not only that the accused organism is present in those who suffer, but that it is all but absolutely absent in those who do not have and never have had measles.

If we compare diphtheria to measles, it is immediately evident that the conditions of conveying the disease directly, so far as mere transmission of the contagious substance is concerned, is nearly the same. The same excretions are contagious in each case, and the sick are of the same age with the same habits. Doubtless the duration of the danger is longer in diphtheria, while the transmission may be favored by the fact that cases of measles are less confined. Fluegge has recently published an account of the epidemic of diphtheria in Breslau in the five consecutive years ending in 1890. There were 6,349 cases reported. Yet the houses, and still more the families, in which there was more than a single case were exceptional. On the other hand, in the fifty houses where there were the greatest number of cases, with three exceptions, the cases were not simultaneous, but followed in a chain of single cases at intervals of a few weeks, exceptionally of six or seven months. The mode of spread was thus entirely different from that of measles, and this difference can only be accounted for on the supposition that temporary and permanent natural insusceptibility is very common in the case of diphtheria, and very uncommon in the case of measles.* How many persons are naturally insusceptible cannot be arrived at with exactness. In the five years studied by Fluegge the proportion attacked yearly is given in comparison with the population living at the same ages. After twenty similar years one-fifth of the population attaining the age to twenty would have had the disease. On the one hand diphtheria was more than usually prevalent during the period under consideration; on the other hand it cannot be assumed that all children were exposed.

Enough has been said to show that in diphtheria something more is evolved than contamination of the pharyngeal surfaces with the virus of diphtheria in the transmission of this disease, and that this something is a condition of the tissues which only exists simultaneously in a few persons, and probably never exists in some.

The facts of diphtheria epidemics are sufficient to show that we must expect to find at times the germ of the disease unassociated with lesions of any sort in persons who have been directly or indirectly exposed to the disease, but do not acquire it.

These questions have been gone into at some length in part because they deal with the objections which are commonly made against the dominant bacteriological theory of diphtheria, and still more because they bring out the difference which may be expected to exist between the bacteriological and clinical diagnosis of diphtheria. Those who call bacteriology to their aid must expect to find on the one hand that some of their white anginas—to use a Gallic expression—are not diphtheria; and again other cases in which a definite membrane does not exist in any stage of the disease, will be shown to be diphtheria, and however mild themselves, will endanger all around them. Even purely catarrhal pharyngitis will be found to be diphtheria, since we mean by this term, not a

*Fluegge, Ztsch. Hyg. Vol. I, 3, p. 401.

definite pathological process, but the whole series and variety of pathological changes which the Klebs-Lœffler bacillus can initiate in mucous membranes and elsewhere. According to Ritter, indeed, this bacillus always exists in Bretonneau diphtheria. In over three hundred cases examined by him the bacillus was found absent in so few that he prefers to believe that in these few cases the organism was really present, but was not found on account of some defect in the technique. Unfortunately, in the publications seen by the writer, Ritter does not define with exactness what he means by Bretonneau diphtheria. The work of other observers has shown very decisively that a distinct membrane frequently exists without the presence of the bacilli.

It may be asked, if the bacillus may be present or absent in cases which are clinically diphtheria, what is the importance of the examination. When the clinicians had to accept the distinctions of pathological anatomy and epidemiology, they naturally went to work to discover the clinical signs which corresponded to the various pathological conditions. Precisely the same work is now going forward in ascertaining the clinical facts which correspond to bacteriological distinctions. Much of this may be left unnoticed as too recent, but some of the results are well ascertained.

While there have always been found a considerable proportion of mild cases among those characterized by the Klebs-Lœffler bacillus, yet nearly all the fatal cases of pseudo-membranous disease of the pharynx contain it.

In 1892* Baginsky reported the results of the bacteriological diagnosis in 154 persons who had been sent to his hospital as cases of diphtheria. Of these, 118 showed the presence of the Klebs-Lœffler bacillus; in 36 it was absent. Of 118, 45 died, or 38.19 per cent. Of the 36 who lacked this microbe, 4 died, or 11 per cent. Of these four, however, one was brought to the hospital with severe diphtheritic paralysis and died in consequence. Another was complicated with severe measles, and died of an extensive pneumonia. The other two died of double empyema. The remaining thirty-four cases went on to recovery without any complication in a short time. A similar difference in the case of mortality has been noted by many subsequent observers.

Thus Chaillou and Martin,* in ninety-nine cases sent to the diphtheria wards of the Hospital des Enfants Malades, Paris, found twenty-nine free of the bacillus, none of whom died. In the remaining seventy there were twenty-eight deaths. In general it may be said that the white anginas, due to other causes, offer about the same danger to life as measles.

As a rule the course is shorter; and while the symptoms are sometimes threatening at first, there is usually a rapid improvement and the duration only occasionally reaches eight or ten days.

Martin and Chaillou attempt to discover what clinical distinctions vary with other pathogenic germs present, both when associated with the Klebs-Lœffler bacillus and when it is absent. They are in accord with nearly all who have studied the question in ascribing a particular severity to the class of cases in which streptococci are associated with Klebs-Lœffler bacilli.

Finally the ancient struggle over the distinction between croup and diphtheria deserves mention. The bacteriologists have shown that the same distinctions divide this disease as the anginas. In ninety-nine cases of croup studied by Martin and Chaillou, twenty-eight showed no membrane in the throat. Seven of these lacked the diphtheria bacillus. In twenty-one they were present. In the seven cases there was one death. In the twenty-one there were ten deaths. In addition there were seven cases with three deaths in which diphtheria bacilli were not discovered until after tracheotomy had been performed, and it was believed by the authors that this was the result of infection in the hospital wards. Finally it may be added that the Klebs-Lœffler bacillus was found in 80 per cent. of the cases diagnosed croup in New York.

Do Not Prescribe Alcohol.

Physicians, as an educated and enlightened body of men, should never recommend alcohol unless absolutely necessary. They should endeavor to imbue the masses of mankind with the thorough understanding of the mental havoc and physical destruction wrought by this terrible agent.

SHOULD THE CARDIOPATH MARRY?

W. T. ENGLISH, M.D., PITTSBURG, PA.

Intimately associated with the physiological and pathological phases of this inquiry are those of a sentimental and ethical nature. While a brief study of the phenomena attending gestation under physiological conditions of the circulatory apparatus, and a comparison with the pathological modifications in the cardiopath, will subserve the paramount object of this paper, some other considerations are inseparably connected with a discussion of the subject. To the noblest and best woman there is something inestimable and beyond comparison on earth to the full, wide, spiritual mission of motherhood. Marriage is the only plane in which she can expect to attain the goal of all that is worldly and unwordly, and where she may acquaint herself with the mighty mystery which is the portal of the race.

This innate desire for motherhood must not be thoughtlessly denied. Especially is it desirable that we consider well any proscription that may give excuse to those who shirk maternal obligations. Many a strong woman of to-day prefers to storm the hitherto man-garrisoned citadels, instead of entering the holy-of-holies of wholesome motherhood, for which nature has so loftily endowed her. Her dreams of home are yielding to lucid and verbose novels descriptive of neurotic frenzies and masculine decadence. Even her pen touches the pages with theoretic knowledge of heredity, pathology and diseased babies. But while the avenues of commercial and literary competition are choking, the holy realm of childbirth is left to those who are not always physically competent.

From whatsoever reason women miss their obvious destiny they are, from Nature's point of view, failures. No single life can be a perfect life. On the other hand no greater selfishness can be imagined than that which brings children into the world doomed to death, or to a life of immitigable misery. Each child has a right to know the life into which he is to be born. No human should have his pre-natal interests so far forgotten in this 19th century that we shall be forced to fight a losing battle against disease and death. Morbid courtships and hectic marriages belong to the time that is past. Physical considerations must, then, have somewhat to do with marriages and child-bearing. The social plane in which the prospective progenitor moves may have an important bearing, and even sentiment be of utility, when we attempt to answer the query: "Should the cardiopath marry?"

Every physician knows the intimate association the womanly functions have with the circulatory apparatus, and the direct influence upon the heart demeanor of the disturbance of the menstrual flow. On the very threshold of conception there are evidences of perturbation as exemplified in palpitation, irregular rhythm of the heart, and respiratory limitations. As each month wheels its round, we watch with interest the increasing stress under which the heart labors, that it may hide its expenditure of energy on behalf of the developing fœtus from the various organs which have hitherto had sole claim upon its efficiency. Now it conceals unrest by an appeal to the vaso-motor center in the medulla, and anon it quiets a threatened tumult by recourse to its accelerator or inhibitory connections with the vagus and sympathetic supplies; holding in reserve for a more final appeal, its own ideo-motor capacities, controlled by intrinsic plexuses and ganglia. Meanwhile some rebellious organ, as the stomach, adds to the difficulties by mechanical, physiological or pathological mal-behavior. Even while these efforts are expended to control violations of cardiac calm, there is developing in the uterus, and its expanding vessels, an ever-widening circulatory area, over which the belabored heart must propel the blood; and, in consequence of the augmented volume of the circulating fluid, it is required to pump more blood in a given time. The task increases as gestation progresses, not only because of the additional labor, but also on account of the

perverted and weakened quality of the blood. The response to the demand for enlarged propulsive power is an hypertrophy of the left ventricle. The auditory evidences of these changes in the organ and the blood, are in the increased heart-sounds and murmurs at the cardiac base. Plethora exists as to quantity and anæmia as to quality. Pregnancy thus inaugurates heart injury that ultimates in degenerative changes which may continue to a fatal termination.

In the circulation of the pregnant woman there is need for extensive resiliency, and nature grants a capacity for tolerance of gastric caprice, renal aberrations, blood changes, respiratory embarrassment, neurosal deviations and varied psychoses. In the presence of the morbid heart, any one of these manifestations is liable to pass beyond the line of the physiological. Dangerous symptoms are extremely apt to arise when there is such a wide range in the vascular tonicity as is present where the heart is incapable or sluggish from disease. A fair adjustment may be achieved throughout all the details only to finally fail at the puerperium. For when the zenith point in the pregnancy and the circulatory distension is arrived at, the heart and womb must expel their contents or serious dangers will uprise. This depletion is sudden and effectual; but, nevertheless, it must also be succeeded by the lochial drain, continued in gradual manner for weeks. The danger is imminent when there is pronounced interruption; and, if there is impairment of any portion of the circulatory mechanism, it will most likely prove fatal.

Nature enters her protest against all the acts associated with pregnancy when attempted in the presence of cardiac disability. The excitement incident upon coitus is in itself a trial to which the heart has succumbed when in all the ecstasy of sexual embrace. Notwithstanding that age, temperament and disposition has each made its special co-efficient of force, which may enter into the estimate for good or ill, the fact has been demonstrated that the heart has yielded regardless of each and every one when under the thralldom of sexual orgasm. Sterile cardiopaths cannot be considered safely marriageable. The Malthusian practices, which are so common in France and have been suggested as a means of comparative protection to the cardiopath, are never safe in any respect. Moreover, any marriage which would thus tend to increase the number of Malthusian men, women and children in the world is a trespass upon the moral domain for social ends.

A rational conclusion from the facts already rehearsed would be, that the cardiopath would be greatly influenced by her sphere in life and social plane. A perfect estimate of the consequences would at least include a brief reference to those conditions for good and ill that constitute her environments. It is generally observed that those high in the social plane are not likely to precipitate themselves into the difficulties of marriage without deliberate thought. This gives opportunity to develop and detect impediment. A more general and probable access to the advice of a physician protects still further. Marriage is therefore less common among cardiopaths in the higher social planes. If marriage and pregnancy do occur, rest and ease are the daily portion of the woman. The surveillance of a physician is provided, and his advice carefully followed, often with the aid of efficient attendants. Pregnancies are rarely repeated.

Upon the other hand, there is poverty of blood vouchsafed to her who never experienced, and therefore cannot be expected to appreciate cleanliness, and for the same cause may not be emulous of bright surroundings. Food, air, and temperature are elements which exert potency that is of vast importance in cardiopathic gestation. Constant and exacting drudgery and toil are bad medicines for the injured heart. Upon the submerged class worry lays an awful hand, and among these, the calamitous sequlæ to emotional causes attain their zenith point. Urban life pre-supposes a denial of some of the advantages accorded to those in suburban or country districts. There is a sentimental shadow that steals over the heart burdened by pregnancy and disease that is unmeasured by those who feel only that which is real. It means poverty of home, poverty of blood, poverty of life, plus the anæmia and distress of pregnancy. To those low in the scale, the boundaries of difficulty geometrically expand. Their surroundings conspire to make greatest caution of paramount importance, and at the same time limit the possibility of its achievement.

Mortality statistics are not extensive, but the death rate to the cardiopath during gestation, and at puerperium, proves to be very high. Porak, of Paris, in 1880, reported 92 cases, with a death rate of 38.09 per cent.; Reny, of Nancy, 1880, 38.8 per cent. Wessner, 77 cases by him collected, 37 per cent. died; Schlayer reports 25 with 10 deaths; Leyden, 20 with 11 deaths. Sears collected 30 cases in Boston last year with 10 deaths. These are the number of women, not their pregnancies, and are of cases where severe conditions arose.

Among the few experiences which have fallen to my lot in my earlier practices in this city, I recall one who has passed through repeated pregnancies with a grave mitral lesion; and it is the mitral lesion that is most commonly found in fatal cases. The aortic is rarely present as a very dangerous complication. This is partly due to the general distribution of cardiac murmurs—those of the mitral being more common before middle life, and these of the aortic valves more frequent in later years.

If the cardiopath miscarry, which her heart lesion will probably guarantee, the history will be darkened with extreme danger. The necessity for abortion appears when there are grave symptoms in the early months. When necessary, it should be performed early. If the case is desperate, abortion may, in itself, add to the peril. Charpentier gives it as his experience and observation that among cardiopaths abortions are very common, and premature labor frequent, and children delivered at term do not have tenacity for life. Casanova states that in more than half the cases, with marked symptoms, pregnancy never reaches a conclusion. Duroziez noted forty-one cases, with twenty-one miscarriages—five deliveries at six months. Of the thirty-seven children born alive only two lived to be five years old.

McDonald claims that the hopefulness of the pregnancy is increased if the stage of compensation is attained before conception; because, if the physiological hypertrophy and the uterine enlargement are combined, they include the possibilities of faulty heart nutrition. Degeneration usually begins about the fourth month. The heart has but little potency remaining if it occurs prior to that time. The degeneration and downward course for the woman is almost sure to follow delivery, and is usually speedy. A degree of conservatism has hitherto prevailed among medical men who have answered the question proposed in this paper. This is because some serious cases have succeeded in achieving a safe delievery; and the fact that the mother has merely escaped with her life is considered by some sufficient to commend matrimony.

Jaccound rather encourages the cardiopath to marry, and assumes that lesion of moderate extent, might be consistent with a comparatively wholesome motherhood. If under thirty years of age, he assumes it should be encouraged. Sentimental and moral considerations are suggested as loudly demanding matrimony for the cardiopath.

There are sects and sticklers for creeds who regard those who oppose marriage for any cause as little better than atheistic. Standing upon their self-erected higher ethical plane, they ignore the physical plea that assumes it is always the greatest good of the largest number to have a small death rate.

On the other hand, Peter insists that, under no circumstances should the cardiopath marry. To our own mind this seems the more logical conclusion. When we carefully review the fatal possibilities linked inseparably with cardiopathic gestation, it seems too full of alarm to be dismissed without a most decisive denial. The woman who dares to plunge into such a fatal tide of probabilities can be compared to one who, infatuated by an access of fear while viewing a dizzy height, plunges into the awful chasm which excites her awe. The end does not appear in their selfish self sacrifice, but they vouchsafe to the fruit of their wombs a legacy of death, and place a stumbling-block in the line of march of humanity toward perfection.

Every thought in the mind of the physician and economist should be directed toward the physical improvement of progeny. It is ours to teach the better doctrine and contemplate the loftiest and most inspiring spectacle of "federation of the world" on this point toward which medicine is surely feeling its way. Each new stride achieved and every old barrier to their consummation beaten down is a strong reason for optimism. However distant the achievement, is is much that it has become the object of effort, not with the few, but with the many.

THREE CASES OF DIPHTHERIA TREATED WITH ANTITOXIN.

W. T. BURLEIGH, M.D., PITTSBURG, PA.

CASE 1. Pearl Hall, aged nine years. I was unable to obtain any antitoxin with which to treat this case until the fifth day of the disease, (Feb. 28). At that time, just before the injection, the temperature was 100° F., the pulse 120. This was in the evening. The next morning after the injection the temperature was normal and the pulse 96. There had been a reduction of the pulse beats from 120 to 96 in twelve hours, and the little girl's mother informed me that she had slept better that night than she had at any time previously, during her illness having complained of a great deal of pain through her head and entire body.

The morning following this, that is thirty-six hours after the injection, and the seventh day of the disease, the temperature was normal, the pulse 84, and the membrane had entirely disappeared.

The patient was discharged the thirteenth day of the disease, and eight days after the injection. The membrane had been confined to both tonsils.

CASE 2. Birdie Armstrong, aged one and a half years, was injected on the evening of the fifth day of the disease, at which time the membrane covered both tonsils, the temperature was 102 2-5° F., and the pulse was 120. The next morning the membrane was still present but in a pultaceous condition; the pulse was still 120, but the temperature was normal. The next morning, or thirty-six hours after the injection, the membrane had entirely disappeared. The patient was discharged on the eighth day of the sickness, or three days after the injection.

CASE 3. On the eleventh day of this month I was called in the evening to see Harry Peterman, aged nine years. He had been ill about twenty-four hours, and was in a profound comatose condition. Membrane covered both tonsils, the pulse was 144 per minute, and the temperature was 103 1-5° F. Twelve hours after the injection, the membrane was apparently unaffected, but the pulse was only 124 per minute, and the temperature was 100 2-5° F.

The next morning the patient was with difficulty kept in bed, the membrane was partially dissolved, the pulse 108, and the temperature 99° F. The next morning, or thirty-six hours after the injection, the membrane had entirely disappeared.

In this case no medication was used, not even a placebo, until the third day, when one-quarter grain doses of calomel were given every two hours to move the bowels. This case was apparently a very malignant one, and would have probably died under any of the former methods of treatment. The parents had lost children before from diphtheria, and had abandoned all hope of saving this one.

The two cases first narrated were treated the first five days with the usual local and constitutional remedies, and these were continued in a desultory way after the use of the antitoxin. These first two cases would probably have recovered anyway, but I believe the length of illness was much shorter, the patients more comfortable and the recovery more certain.

In these three cases, and in one complicated with scarlet fever which I saw in consultation with Dr. Sweeney, there was no paralysis following, and I believe that we can prevent the nervous sequelæ in every case, where we see the case within the first twenty-four hours, and use a strong enough dose.

In the case of Harry Peterman, I was enabled to try the protective influence of antitoxin. A sister's child, a little boy two years old, was there on a visit, and on account of the other children at home they were afraid to take him there, and it was neceesary to keep him in the same room day and night with the diphtheria patient. I gave him an injection of Behring antitoxin 600 units strong, and he did not contract the disease. The same preparation of 1,000 units strength was used for curative effects on the other cases mentioned, and the syringe I am using is a Fisher syringe with asbestos expanding piston, of 15 c.c. capacity. There was no reaction, local or general, following the injections.

THE MEDICAL AND SURGICAL REPORTER

ISSUED EVERY SATURDAY

Address all communications to P. O. Box 843, Philadelphia, Pa.

HAROLD H. KYNETT, A.M., M.D.
Editor.

RODERIC C. PENFIELD
Publisher.

Editorial Offices, 1026 Arch Street, Philadelphia, Pa.

Entered as second-class matter at Asbury Park, N. J.

TERMS:—Three Dollars a year in advance. Sent four months on trial for $1.00.

REMITTANCES should be made payable to the Publisher only, and should be made by Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We invite contributions of value to the profession, and if published originally in THE REPORTER such will be paid for at liberal rates, or a limited number of copies of THE REPORTER will be supplied, as the author may elect. Hereafter where reprints are desired writers are requested to make a note of that fact on the first page of the MS., but must order reprints directly from the publisher, who will supply the same at cost rates. Contributors should inclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, APRIL 27, 1895.

EDITORIAL.

AUSCULTATORY PERCUSSION.

It is a noteworthy fact, explicable only on the theory that the human intellect, like a lost traveler, wanders in circles without making much advancement, that the article on Auscultatory Percussion which appears in our present issue, should ever have been offered or accepted as a prize essay.

In 1840, Camman, with the assistance of Clark, published an elucidation of this method of physical diagnosis, which he had recently discovered. Yet the value of his discovery has not been generally recognized by the profession, so that, as the writer of the paper states, any one attempting to investigate the method at present, must be self-taught and his work must be essentially of an original nature, although he can learn from medical literature that there is such an art as auscultatory percussion and can gain a general conception of what he may expect from it.

From one point of view, it is to be regretted that so much of Dr. Benedict's article deals with the stomach and liver. However, it would be manifestly unfair to offer adverse criticism on a necessary consequence of limitation of practice. It seems to us that the careful study of the lung and thoracic cavity, and of the enlarged pelvic organs, by the aid of auscultatory percussion, may develop important diagnostic powers.

Writers agree that the special monaural stethoscope of cedar used by Camman, is unnecessary. This very point, trivial as it may seem, will doubtless determine the adoption of the method by many physicians who would not incur the trouble or expense of buying a separate instrument. A shrewd lecturer once said, that inconvenience had killed more people than incapacity, and it is often enough that the balance of choice between two lines of treatment is swung by some petty consideration which might be offset by five or ten cents. The fact that an assistant is unnecessary—there being no pleximeter finger in use—will also tend to popularize the method.

It is altogether likely that many physicians will take up the method of auscultatory percussion, only to abandon it after a few weeks' trial as of no more service than more familiar methods of physical examination. We would remind any such that no valuable art is mastered in a day; and that if half the claims made for auscultatory percussion are true, it is well worth six months' study. The substitution of friction, the vibrations of a tuning-fork and of an electric interruptor for percussion with the finger, like the automatic tappers invented by other investigators, is ingenious, but, we venture to predict, not destined to take the place of the simpler method. It is matter of common observation that the best surgeons use the scalpel, forceps, scissors and chisel almost to the exclusion of elaborate destructive instruments that have been devised, and the common officinal remedies and simple means of examination are the mainstay of the best medical clinicians.

ABSTRACTS.

COMMUNICATION OF TYPHOID FEVER.

At the last annual meeting of the British Medical Association, Dr. P. W. Williams, Senior Assistant Physician, Bristol Royal Infirmary, reported five cases of typhoid fever as tending to prove that this disease may be be communicated by the breath or expectoration of infected persons. Three of the cases were brothers, and the fourth a nurse who had been nursing the first case. The first, fourth and fifth cases died, and in two of these the post-mortem examination revealed all the typical lesions of typhoid fever, also ulceration of the larynx. As it is practically impossible for any case of enteric fever to be communicated by fæcal contamination in the Bristol Royal Infirmary, by reason of the elaborate and careful precautions taken, and as the first case was delirous and was coughing and expectorating in all directions, it is concluded that in this way the nurse in attendance contracted the disease. The fever in these cases was of peculiarly virulent type. All three in the Infirmary began with very severe headache and bachache, profound nervous prostration supervened very early, and all three died apparently from respiratory failure. In two at least there were laryngeal ulcers, and probably also in the third, the nurse. In one there was purulent discharge from the ear, and in another an abscess formed in the arm. Cultures in agar from the spleen and larynx of the fifth case gave identical micro-organisms corresponding in every respect with the Eberth-Gaffky bacillus of enteric fever. These cases would seem to explain the possibility of typhoid fever being infectious, as maintained by Budd and endorsed by Collie; and emphasize the necessity for more careful prophylaxis in cases which exhibit laryngeal complications. The practical importance of bearing in mind the possibility of typhoid fever communication by the expectoration cannot be over estimated. The true nature of laryngeal ulcers in typhoid fever is still an open question, authorities differing as to whether they are simple catarrhal ulcerations following the somewhat common complications of this disease, catarrhal pharyngitis and laryngitis—or specific ulcers analogous to the ulcers in the intestines. Osler states that he believes that the bacilli have not yet been found in the ulcers, and Fagge, Murchison, Roberts, Libermeister, Strümpell and Bartholow are cited by Lincoln as of opinion that the ulcers are always secondary and not specific lesions of the typhoid process. On the other hand, Klebs, Rokitansky, Landgraf, and Morell Mackenzie are among those who take the view that they are due to a specific deposit upon the laryngeal mucous membrane.—*Pacific Med. Jour.*

DEGENERACY IN LITERATURE.

The Boston *Medical and Surgical Journal* says editorially:

"The recent epidemic of Yellow Books, Green Carnations and New Women in England has led Mr. Charles Dudley Warner to descant, in his own charming way, upon the "yellows" in literature, and to recommend scientists, alienists, and psychological investigators to study it, believing that it signifies disease A study of the sort was made some years ago, before the works above mentioned appeared, by Max Nordau, whose work* an English translation of which has just appeared, has naturally given rise to much criticism.

Nordau was well equipped for the task. In the first place he had been a literary critic for many years, and was thoroughly familiar with modern literature; and, in the second place, he was a disciple of Lombroso, to whom he dedicates his book, and, although not a physician, he had studied neurology and psychiatry very thoroughly, and he was familiar with the morbid mental phenomena of hysteria, insanity, degeneracy and crime. With such a mental equipment, then, which few mere critics could possess, he gives himself to the investigation of certain modern tendencies in art and literature, and to a careful diagnosis of the mental condition of some of the writers who are looked upon by many as leaders in modern thought. As a result he finds that these tendencies have their sources in the degeneracy of their authors, and that the enthusiasm of their admirers is for manifestations of more or less pronounced moral insanity, imbecility and dementia.

Such a study has a special interest for the physician. It might seem at first that the interest would be pathological rather than therapeutic, for it is hard to believe that Mr. Aubrey Beardsley or Mme. Sarah Grand, for instance, would wish to be cured of the morbid manifestations which are their chief title to fame. Nevertheless, if books or works of art inculcate absurd and anti-social doctrines, they exert a disturbing and corrupting influence on the minds of many people, especially the weak-minded and hysterical, and those who adopt every new doctrine which they think is fashionable. We have seen within a few months how much mischief a degenerate labor agitator can do if chance puts him into a position of power. The neurotic are often rendered much more unstable and sometimes actually insane by dwelling too much upon the teachings of the degenerate, whether it be in the field of anarchy, socialism, theosophy, Christian science, or spiritualism. It therefore becomes the duty of the physician, as a matter of public mental health, clearly to recognize the mental stigmata of degeneracy, and to point out to the public the true nature of such conditions and the leading facts in mental therapeutics. Unhealthy books may do as much harm to the mind as certain disease germs do to the body, and it is not against the so-called pornographic writers alone that the public should be warned. The physician too often gives precise directions about the preparation and ingestion of food for the body, while he too seldom considers what food is offered to his patient's mind, and yet a course of Ibsen or Tolstoi or Maeterlinck may do as much harm to some persons as devilled kidneys, Welch rarebits, or mince pie. Only by a careful study of the mental stigmata of degeneracy can the physician prescribe what Nordau calls the effective treatment of the disease of the age: "Characterization of the leading degenerates as mentally diseased; unmasking and stigmatizing of their imitators as enemies to society; cautioning the public against the lies of these parasites."

The physical stigmata of degeneracy have been fully enumerated by Morel, Lombroso, and others, and they are beginning to be mentioned in the modern treatises on nervous diseases. Nordau enters into an elaborate study of the mental stigmata, which are also well recognized by alienists and neurologists. The sensory apparatus of the degenerate may either be so irritable that a slight stimulus will give rise to a very marked response, as when a color, or a bar of music, or an ordinary verse of poetry fills him with a strange thrill or shudder; or it may be so sluggish as to be aroused only by the hor-

*Max Nordau, Entartung, Berlin, 1893; Degeneration, New York, 1895.

rible or the disgusting. In the one case he may be proud of his excitability, and consider it proof of deep appreciation; in the other he may, with equal pride, consider himself above the ordinary prejudices of humanity. With it all he is selfish, conceited, and extremely emotional. A sensation ordinarily excites many different cells in the cortex, giving rise to many associated ideas, but the healthy mind disregards the unimportant ideas thus aroused and concentrates its attention only on those which are essential. The degenerate is weak of will and incapable of fixed and prolonged attention; the unimportant ideas thus called into activity are not ignored, but fill his mind with a jumble of vague and obscure notions, which suggest strange relations. A word may thus call up other words of similar sound but with no related significance, and we have the phenomena known as echolalia. With vague and obscure ideas and unusual associations, the degenerate is incapable of clear thought and often becomes a mystic, finding hidden significances and inexplicable relation in all things. In other cases, with a prevalence of insistent ideas, his own personality becomes the dominant factor in his world. In cases where the sensory apparatus requires powerful stimuli, or where sexual or other animal instincts give rise to insistent ideas, he may show evidences of sexual perversion or denounce the ordinary laws of decency and custom, and be classed as an anarchist. In other cases he may be filled with vague and impractical ideas for the regeneration of society, and preach social reform. In most cases, unhappily for society, he has a morbid desire either to talk or write, and indulges that desire constantly.

Having thus set forth the leading mental characteristics of degeneracy, which, it is needless to say, are in the main accepted, Nordau carefully studies the works of various writers and brings forward the evidence that they are degenerate. Rossetti, Swinburne, Paul Verlaine, Mallarmé, Tolstoi, Wagner, Péladan, Maeterlinck, Walt Whitman, Baudelaire, the French symbolists and décadents, Oscar Wilde, Ibsen, Zola, Nietzche, and many others; all are weighed in the balance and pronounced degenerate. In many cases there can be no question as to the justice of his criticism; apart from their writings the known facts in the lives of such men as Poe, Verlaine, Maupassant, Nietzche, and Tolstoi prove his assertions. In the main, too, although his criticism is savage, and his pleading at times special, the facts which he adduces more than substantiate his assertions.

It cannot be denied that in some cases the degenerate may possess great abilities in some directions; but he will be, as Lowell said of Poe, "three-fifths of him genius and two-fifths sheer fudge." He lacks harmony and balance; his mental development is unequal, and his influence does not advance the world, but it is always unhealthy; like Carlyle, "he leads men into the wilderness—and leaves them there."

It is the tendency of the degenerate to associate with his kind, the criminal in the Mafia, the mystic in a religion, the esthete in a cult. Around those groups cluster many neurotic persons, who suffer from "the restless seeking of the modern soul for a new ideal," who are also incapable of clear thought, and who call that deep which is only obscure, incomprehensible and absurd. When the sect is once formed, many others join simply to keep in the fashion or to seem "advanced," and with them come the social strugglers who are always eager to win money or notoriety by adopting every new fashion. Degeneracy is not necessarily, as Nordau thinks, a disease of our age, but its stigmata may be found throughout literature, in the mysticisms of the Neo-Platonists, the sentimentalism of Rousseau, or the indecencies of the Marquis de Sade. It is, however, to-day, with the dearth of great writers, much more in evidence, and it becomes the physician's duty to show that these idols of the present are false gods.

Toxic Effects of Thyroid Feeding.

Beclere presented to the Medical Society of the Hopitals, Paris, a patient illustrating the cure of myxœdema by thyroid therapy. During the course of her treatment she accidentally took a large quantity of tyroid gland—92 grains in eleven days. At the end of this time she had developed such symptoms as tachycardia, pyrexia, insomnia, tremor of the extremities, exophthalmia, polyuria, albuminuria and glycosuria; in fact, a complete picture of Basedow's disease. The writer, therefore, concludes that the latter disease is due to a hypersecretion of the thyroid gland, which may be caused in more ways than one.

SOCIETY REPORTS.

ALLEGHENY COUNTY MEDICAL SOCIETY.

March, 19 1895.

Dr. W. T. English opened the discussion of the subject announced for the evening, entitled:

SHOULD THE CARDIOPATH MARRY?

(See page 599).

DISCUSSION.

Dr. W. D. KEARNS: This is certainly a subject which deserves a good deal of reflection, and upon which there is quite a diversity of views. The views of the reader of the paper are certainly orthodox. How to reach these cases before the harm is done is a difficult question. Many young women are undoubtedly suffering from cardiac lesion, who do not consult a physician. I think the gravest reason why the cardiopath should not marry, is on account of her offspring. And then again, we cannot foretell the results of a slight cardiac lesion or what will occur in the course of time. Hypertrophy of the left ventricle is only the first stage, and the disease may never go beyond this stage. Hypertrophy of right auricle and ventricle is the second stage, with many evils attendant upon it. But, gentlemen, is this stage always reached? If we are to prohibit such young women from marrying, may not the same or worse results occur from other causes; for instance, cycling?

A slight muscular overstrain, in a person suffering from a slight cardiac lesion, may bring on hypertrophy of the right auricle and ventricle. But to return to the original discussion, should a woman get married who has a cardiac lesion? I trow not. But has not the husband, or rather the man, just as sharp a line of duty to follow? I think this should be just as binding on the man as on the woman. God gave no man a right to make a woman miserable or to destroy her happiness. If we are to make a rule for the survival of the fittest, we must exclude the man just as much as the woman. Take the subject of tuberculosis—pulmonary tuberculosis, and in thirty years of obstetrical practice I have studied the effects of this disease upon the uterine impregnation. And I feel more and more every day that the marital exclusion of persons having a tubercular taint should be more prominently brought forward and applied to both sexes—to the man as well to the woman. On the point of the cardiac lesion, I do not take quite as extreme a view as the reader of the paper, but I believe if he errs at all, he errs on the right side.

DR. J. M. BATTEN: It is a fact that some families "breed down" physically and become extinct, and that other families "breed up;" and this is, I believe, due, to a certain extent, to improper selection. I do not think it is the duty of any man to select a woman who is diseased in any way; but after a man has selected a partner who has a slight heart affection, I cannot see any reason why it would not be proper for the woman to bear children. I would consider this question affirmatively because, in the majority of these instances, the child will take the constitution of the father. We have no proof that heart disease is hereditary. I have attended some cases of mothers who had heart disease, who bore exceedingly healthy children—nothing the matter with the heart at all. I suppose the reason for this was the children took the constitution of the father. In one case of confinement which I attended the mother had heart disease, and during the course of the pregnancy see had several attacks of hemoptysis, and that lady is still living. I might mention also a case which came under my notice, of a man who had heart disease, and who died in the act of copulation.

DR. ADOLPH KŒNIG: Considering the fallibility of our judgment in matters of this kind, it seems to me that we take considerable responsibility on our shoulders when we declare to a young woman or a young man that they must break off some engagement into which they have

entered, and live a life of celibacy. When we remember that many cases of heart disease will go to old age without serious difficulty arising, it seems to me we are not justified in saying to any human being, "You must not marry;" especially when we know that in many cases of heart disease a married life is not more dangerous than a life of celibacy. I remember Prof. Flint's advice regarding prognosis in cases of heart disease. He always took a middle ground. He said that the safest course was to tell the persons that they were far from being well or in perfect health, and that they must guard carefully against excesses of any kind, or in any direction, and if this care was observed they might live out the ordinary term of life. I think all of us may have seen cases of such individuals, in whom life was prolonged, even beyond the limit accorded to more robust persons, simply because they knew they must guard against excess of all kinds. Many of these cases alos pass a more healthful and happy life on account of this constant care exercised to avoid excess or exposure. I recall to mind a case on which I was called upon to pass judgment, some ten years ago, of a young woman who had valvular heart disease. I did not feel justified in telling that young woman that she must give up all hope of a happy married life. She married, and I must say that subsequent events proved that I would have done her a great injustice if I had denied her her present happiness. Of course, many cases may end disastrously, but they might have ended just as disastrously without the marriage relation.

Dr. Theodore Diller: The late Sir Matthew Arnold had valvular heart disease and was told so by his physician, Sir Andrew Clark, more than twenty-five years before his death, and yet it is a fact that he did nearly all the best work of his life with the full knowledge that he was suffering from this organic cardiac leison. I have often talked with older practitioners on this subject, in which I have always been interested, and have been told of many cases of persons who have gone through life with heart murmurs without the lesion affecting their daily work to any appreciable extent. I have myself followed some cases for eight or ten years, and must say that my own ideas are very much at variance with the teachings of most of the medical schools of ten years ago. To my mind it does not mean very much of itself to say that a woman has a heart murmur; it may or may not be a serious matter. Life insurance companies are beginning to realize that a heart murmur is not necessarily a menace to life, and some of them will insure cases of this kind. I think that the prognosis in the majority of these cases has been entirely too gloomy.

Dr. John Milton Duff: I do not want to enter into an exhaustive discussion of this question, but I would like to bring forward one or two points in connection with it. Theoretically I agree with the paper of Dr. English. It might be even said that if the sole object of life was to improve our race, we should prohibit the marriage of all persons who are not in perfect health. I do not think, however, that a woman with a slight heart lesion undergoes any more danger during pregnancy and child-birth, than does a woman suffering from many other lesions. But we are not to consider that all heart lesions are hereditary, and that is one point in which the doctor should have made a distinction. If I produce disease of my heart by excitement, by calisthenics, or by overlifting, a consequent hypertrophy of the left ventricle and the succeeding conditions following in the right and left auricle, I am simply suffering at that time from a traumatic condition, and it would be almost as logical to say that I should not then marry because of the evil effects upon my progeny as it would be to assert that I should remain single because I had lost a limb. I admit that as far as my personal experience goes it has not been very extensive, but I can recall but few cases in which I feel confident that pregnancy did really impair the condition of the heart. We all know that during pregnancy there is a dilatation of the heart, and that this dilatation is accompanied by temporary hypertrophy. Now if there is a hypertrophied condition of the muscles of the heart before pregnancy, this hypertrophy will naturally be increased somewhat during pregnancy, and there will be a change in the structure of the fibers of the muscles of the heart, just as there is in the uterus. After delivery there is a retraction and contraction and there will be an absorption, and all this

may bring about an ultimate condition in which the pathological symptoms all disappear. This may be theoretical, but in two cases of my own the resulting conditions seemed to verify it, and the subsequent health of these cases justifies me in calling your attention to pregnancy as a possible cure of cardiopathy. I was very much interested in the excellent paper.

DR. W. C. SHAW: I wish to state that I have had some personal experience with cardiopathic marriage.

Some time after I had become exgaged to the lady who afterward became my wife, I discovered to my utter amazement that she had valvular disease of the heart, and about as bad a case as you will ordinarily meet. The question which now confronted me was what my duty was under the circumstances. As I had not discovered this lesion before becoming engaged to her, I married her, and although the cardiac lesion was the direct cause of her death, complicated by pregnancy, yet she raised three children, two of whom are yet living; however, I think a man with his eyes open, and a medical man at that, should think very seriously before entering into the marriage relation with a cardiopath. Was it an exception that death occurred at the fourth pregnancy instead of at the first? I was only permitted to live with her a little short of ten years, wanting eight days only.

I consider the question of cardiopath marrying a very serious one. The woman is in danger from disease and death, and the husband is in danger of losing his wife.

DR. BATTEN: Are your children now living healthy?

DR. W. C. SHAW: Yes, sir.

DR. W. T. ENGLISH: Mr. President and Gentlemen—It seems to me that the discussion of this paper has taken a very different phase from the paper itself. The principal point which I desired to make and emphasize was that a cardiopathic *woman* should not marry, and the fact that I omitted from the discussion the masculine gender is a tacit admission that they are not to be considered.

Please rehearse the points made: In the first place we have a woman with heart disease jeopardizing her life, and shortening her days, and it seems irrational to say that such a woman could become pregnant with safety to herself. I think it would be very wrong for her to ever marry, because marriage would necessarily bring about pregnancy; and the evil consequences would be multiplied againt her. She would voluntarily increase her own danger; but the danger does not stop here. It continues on to the fœtus. I think the statistics in my paper prove this latter point conclusively. Pregnancies rarely go to term, but patients generally abort either from accident or necessity. At times it becomes the duty of the physician to produce an abortion and thereby relieve the immediate conditions. When they go to term, then what? All the statistics which I have been able to gather go to show that the offspring of the cardiopath rarely live five years. I think it most irrational to assume that the cardiopathic woman should marry under such circumstances. With regard to themselves and with regard to their progeny, the physician's advice should always be against marriage. So far as the men are concerned, I leave them out of the question.

I desire to take exception to the statement of Dr. Diller that insurance companies would insure persons having cardiac lesion. No regular insurance company would accept such a risk. The companies which will take such an applicant are classed as extra hazardous, and they charge the entire premium on the payment plan against the policy, allowing that premium to be deducted by the annual payment, requiring some twenty years to pay off the claim. In reality there is a lien against the policy for the entire premium, figured at the annual rate which obtains at the age the policy is secured. If death occurs the first year, the entire amount of the premium is deducted from the face value of the policy.

Acute Tonsillitis.

Salicilate of soda is recommended as little less than a specific in acute tonsillitis. It should be given as early in the attack as possible, and in sufficient doses to cause ringing in the ears. Fifteen grains every three hours will usually cause this effect, when the dose may be diminished to ten, and then to five grains at the same intervals. It should be continued a day or two after disappearance of the fever.—*Medical Summary.*

PERISCOPE.

IN CHARGE OF WM. E. PARKE, A.M., M D.

MEDICINE.

Treatment of Renal Colic.

In persons who are subject to the uric acid diathesis, attacks of renal colic are of not infrequent occurrence, and they are commonly attended with such agonizing pains as to leave the sufferer in a prostrate condition for a considerable time after their disappearance.

Although during the attacks little can be done except by the administration of morphia, chloroform, phenacetine and other analgesics, to relieve the pains and render the patient more comfortable, much can be done in the interval to prevent the occurrence of the trouble.

Observations during the past few years have shown that piperazine, in connection with copious draughts of water, is capable of rendering decided benefit in this class of cases.

Although its physiological action is not as yet perfectly understood, piperazine is acknowledged to be the most effective solvent thus far brought forward for uric acid. It keeps the uric acid in the blood in a soluble condition, preventing its deposition in the various tissues, the kidneys, joints, etc., and also dissolves uratic concretions that have existed for some time in these localities.

A considerable number of cases of renal lithiasis have been reported in which the administration of piperazine has been followed by an abundant discharge of gravel in the urine, relief of the pains in the region of the kidneys, and of the hematuria, if present. Its prolonged use in these cases has also insured the patient against a recurrence of the attacks of renal colic, and thus greatly aided in their restoration to health.

Piperazine-Bayer should be administered, as already stated, in a liberal quantity of water, and, in view of the chronic nature of this affection, it must sometimes be employed for a considerable time.

Acute Diseases of Childhood.

In the treatment of the acute affections of childhood, the physician is often confronted with the problem of how to reduce high temperature rapidly and effectively and without injury or discomfort to the patient.

Among all the remedies hitherto proposed, phenacetine still maintains its position as the most eligible antipyretic in pediatric practice. Its popularity is based upon its possession of marked sedative and anodyne properties, aside from its power of reducing fever. Under its influence the restlessness disappears, pain, if present, is relieved, and the child often drops into a refreshing sleep.

In an interesting article in the *Archives of Pediatrics*, March, 1895, Dr. C. G. Jennings states that among the coal tar antipyretics, "Phenacetine has given by far the most satisfactory results. Clinicians generally agree that powerful effects like cyanosis and dangerous cardiac depression never occur with this drug with a reasonable dosage. The beginning dose of phenacetine should never be larger than one half grain for each year of age. This dose may be repeated every hour for two or three doses. Guided by the thermometer or the relief of the distress and the breaking out of a gentle perspiration, the administration of the drug can be arrested when the result is accomplished."

In the treatment of acute nasal and pharyngeal catarrh, tonsilitis, laryngitis, bronchitis, pneumonia and pleurisy in the first stage, the author advises the combination with aconite of one, two or three doses of phenacetine at hourly intervals, at the height of the pyrexia. After the period of engorgement in pneumonia and any grave inflammatory disease, however, the aconite should have no place in its therapeutics, and antipyresis should be accomplished by the bath or phenacetine, administered with very great care.

In the pyrexia resulting from the absorption of ptomaines, and the acute indigestion of childhood, phenacetine, in Dr. Jennings's opinion, is *par excellence* the remedy. It can be administered with calomel, bismuth or salol to suit the necessity of the case.

He also states that in the acute inflammation of the cerebral and spinal meninges, tubercular meningitis, and leptomeningitis, and cerebro-spinal meningitus, phenacetine will be the antipyretic to administer, as it promptly relieves the agonizing headache and neuralgic pains and induces quiet and refreshing sleep. He has found this remedy very serviceable in the exanthematous fevers. In measles the high fevers attending the onset and acme of the eruption stage can be well and safely controlled by phenacetine, while in scarlatina, of a mild and moderately severe type, the administration of one or two doses, when the pyrexia becomes uncomfortable, is good treatment. The same experience was obtained in the treatment of variola. Finally, in malarial fevers and in typhoid fever of a mild type, phenacetine, in the author's opinion, has best answered the purpose of an antipyretic.

A New Method of Narcosis.

At a meeting of the Berlin Medical Society, Dr. P. Rosenberg described a new method of combined anæsthesia which he trusted would entirely prevent the lethal action of the chloroform on the heart. He has demonstrated by experiments on animals that cardiac syncope during chloroform narcosis is due to reflex irritation originating in the nasal mucous membrane and transmitted to nerves having a paralyzant action upon the heart and respiration. By anæsthetizing the

mucous membrane of the nose with a spray of cocaine these reflex disturbances are prevented, and, in view of the fact that cocaine is an antidote to chloroform, its absorption will in another way obviate the injurious effects of the latter. If the nose is previously cocainized, anæsthesia is more readily induced, is attended with less disturbances, and especially is free from after effects. The patients wake up rapidly, and experience none of the usual discomforts.

Amylene Hydrate.

Harmack and Meyer (*Zeitschr. f. Klin. Med.*) have arrived at the following results after careful investigation of the physiological properties possessed by amylene hydrate. Like alcohol, it first excites and then successively paralyzes all the nerve-centres. In graminivorous animals quiet sleep is produced, whereas in carnivora the symptoms of excitement and intoxication are more pronounced. The fatal doses were found to be 15 to 30 grains per kilogramme weight of animal. A very marked diminution of temperature is produced, intensifying the danger to life. Muscular spasms produced by poisons, such as santonin and picrotoxin, are delayed or alleviated. The excretion of urea is diminished, and, finally, it cannot be employed subcutaneously, owing to the severe pain produced.

Duboisin as an Hypnotic.

P. S. Skuridin (*Vratch*) used hypodermic injections of duboisin in twenty one cases of sleeplessness in the insane, the dose varying from $\frac{1}{150}$ to $\frac{1}{75}$ grain, and the grand total of injections amounting to three hundred and sixty. In one hundred and fifty-three (forty-two per cent.) cases the duration of induced sleep exceeded six hours, while in one hundred and twenty-six (thirty-five per cent.) it oscillated between four and six hours, and in sixty-two (eighteen per cent.) was under four hours. In nineteen (five per cent.) the drug failed altogether. The writer comes to the following conclusions:

1. Duboisin will occupy a prominent place among hypnotics for the insane.
2. The best results may be expected in epilepsy, periodical insanity, and acute mania and mental confusion.
3. The hypnotic effect is a secondary phenomenon, developing consecutively to the subsidence of a motor or muscular excitement; hence the drug proves most useful in insomnia caused by intense motor excitation. In sleeplessness depending upon illusions, hallucinations, or organic brain disease, but unaccompanied by distinct motor disturbances, the remedy remains inefficacious.
4. The drug is free from accessory ill effects.

Potassium Permanganate.

In the Canadian *Practitioner*, Chambers concludes a paper detailing some experiments on this subject as follows:

1. Potassium permanganate in dilute solution, not stronger than one grain to an ounce, may be given by the stomach without danger.
2. Potassium permanganate, subcutaneously, is poisonous.
3. Potassium permanganate, grain for grain, completely decomposes morphine, the decomposition occurring in acid media more rapidly than in a neutral medium.
4. Food-stuffs and acetic acid do not interfere with the decomposition.
5. Potassium permanganate is an efficient antidote if taken while the morphine is in the stomach.

The question still remains as to whether potassium permanganate is of therapeutic use after the morphine is absorbed into the system. It has been proved conclusively that if morphine is introduced subcutaneously into the system, it is excreted into the stomach. Now, the morphine passes from the blood into the stomach by osmosis and by excretion, and, by the principle of osmosis, more morphine will be excreted if it is decomposed as soon as it passes into the stomach. Reasoning on this principle, we would expect that repeated small doses of potassium permanganate by the stomach would be of use in cases where the morphine has been absorbed into the system. This is rendered more probable by the fact that morphine, as a rule, is a slow acting poison.

Diet in Gout.

A. Bogdanoff has studied in Professor Obolenski's clinic the influence of animal, mixed and vegetable diet in four patients, three of whom suffered from gout and the fourth from round ulcer of the stomach. The latter patient was given only milk as a food. The mixed diet was found to cause the greatest daily excretion of urine and of uric acid. The specific gravity was between that of the urine in vegetable and that in animal diet. The body-weight increased most under the influence of vegetable diet, diminished under mixed diet and fell greatly under meat diet. In the fourth patient, although the daily quantity of urine was as great, with a slightly acid reaction, the quantity of uric acid was small. The author concludes from these experiments that the diet of gouty persons should not be heavy, but nourishing, and tending to increase the number of white blood corpuscles. For this purpose mixed diet answers best. Pure meat diet acts badly from a psychical standpoint, frequently causing a great antipathy to meat, a tendency to eat little and to drink less, and in this manner diminishing the quantity of urine considerably. Constipation is also often observed.

Common Diseases Mistaken or Mistreated.

The author, James F. Goodheart, spoke of scurvy as being a very common disease in children, and although such cases are often enough recognized, they are constantly allowed to go unrecognized, and pass as rickets, or rheumatism, or injury, or temper, or "pure cussedness" and so on. He thought the cause was usually due to keeping a child

too long on condensed milk or feeding too liberally upon one or other of the infant foods. Condensed milk is an excellent food for infants upon proper occasion, but its constant use should not be continued too long. However, scurvy will sometimes appear with any of the foods, even the best of them. The remedy is pure milk, raw meat juice, good vegetable broths and orange juice as regards foods, and absolute rest in bed with a little opium, if necessary, for the pain. They generally recover speedily but not always. It has twice happened to him that after giving a very hopeful outlook, the child has died suddenly the next day In neither case did the child look worse than many another who did perfectly well. Therefore, until the child has taken to its change of diet and begun to mend, it is as well to speak guardedly.—*Lancet.*

Follicular Tonsillitis.

A paper by Dr. Norris Wolfenden on "The Nature of So-called Follicular Tonsillitis and its Relation to Infectious Disorders," describes recent progress in the study of this disease, with special reference to its bacteriology. The author believes that the time is not far distant when we shall classify the inflammatory condition of the tonsils and throat upon a bacteriological and not a clinical basis. He describes briefly four varieties, omitting all cases in which the bacillus of diphtheria plays a part, under the head of staphylococcal, streptococcal, pneumococcal, and Roux and Yersin coccal angina. In all of these forms there may be throat symptoms which resemble diphtheria. "Follicular" tonsillitis is not really follicular at all; it is an acute cryptic infection due to one of these forms of cocci. Its contagiousness appears established in some cases, but is generally not very easily traced. It never appears to attack large masses of people simultaneously, although a number of persons living under the same roof or in the same conditions are frequently affected at the same time, suggesting unsanitary surroundings as a common cause. The pathological enlargements of the tonsils, in which a chronic process of catarrh is present in the crypts, form not only the best culture media for a large number of micro organisms but give their products an opportunity to invade the system. Clinical appearances alone often allow so little ground for diagnosis of simple tonsillitis from diphtheria that in the absence of bacteriological diagnosis it is wise to isolate such patients from the first

The Treatment of Appendicitis.

Concerning the medical treatment little need be said. Locally, cold alone is appropriate in the beginning, and if slow in development, heat may be of utility in hastening the process. This was exhibited in the second case, seen four days after its inception and operated on on the tenth day.

Internally, opium is by far the most appropriate in all cases where it agrees, and no fears of "masking the symptoms," as some surgeons put it, should be entertained This drug gives physiological rest; and, more than that, it controls the inflammatory process, actually diminishing the calibre of the arterioles of the mesentery and peritoneum better than any other drug yet used.

If the colon be filled with fæcal matter, a mild saline, just sufficient to remove this cause of embarrassment, is appropriate, and for the purpose no prescription is superior to the one used in the writer's cases—namely, fifteen grains of sulphate of magnesium in a half ounce of peppermint water every hour until the desired result is obtained. This mixture is well borne by the stomach and is efficient after a few doses. The diminution of the abdominal contents from the emptying of the gut of fæcal matter and of gas was most marked in the cases where it had been used, and at the time of the operation the freedom from interference of inflated intestines much facilitated the operation.

If general peritonitis develop, possibly the saline treatment alone is more scientific; but this is not settled. In such an event the author has never seen a case which recovered from either medical or surgical treatment, however skillfully it may have been applied.

Salol is of great value, as in so many intestinal diseases, by its efficiency in controlling fermentative processes in the intestinal canal.

The diet should be entirely restricted to fluids; and, so long as vomiting continues, nothing but barley-water or oatmeal-water or ice-water should be permitted. With the amelioration of the primary symptoms diluted milk, with a tablespoonful of lime-water to each glass, may be allowed.

These cases teach that an early diagnosis, the timely association of a surgeon in the management of the case, and the harmonious working together of the physician and surgeon will save many valuable lives that otherwise might be lost to the world.—Heffron, *Medical Record.*

Serum From the Donkey in the Treatment of Tuberculosis.

From a series of observations, Viquerat (*La Medecine Moderne*), affirms that injections of tuberculin in the donkey causes no other effect than an extraordinary increase of the appetite. The serum obtained from this animal, subjected to the intravenous injections of tubercle-bacilli, has been tried by the author first in tuberculous animals and afterward on phthical human beings. The subject was presented by Viquerat in a communication to the Societe Medicale de la Suisse Romande recently. Out of twenty-five cases treated with this serum, one cure and one amelioration were obtained. He presented two cases actually cured, but one was that of a girl suffering from cold abscesses and a cutaneous tuberculosis of the hand. The amount of the serum injected in these cases is not stated, but the author intimates that from 200 to 300 grammes might be a good quantity. The matter, though not received with enthusiasm, was extensively discussed; but, as a whole, the society preferred to assume a conservative attitude.

Bicycle Riding for Women.

"At the meeting of the Societie de Medecine Publique, Mme. Gaches-Sarrante read a paper on the utility of the bicycle for women. For the last three years she has been practicing this masculine exercise to the great benefit of her health. Alluding to the costume to be adopted, she insisted on the fatigue produced by the corset; the least up-hill provokes oppression from the stricture of the thorax. As regards the genital organs, all acute inflammation should forbid the use of the machine; but when the lesions were chronic, moderate exercise might be permitted and even enjoined. In any case, riding is much less fatiguing than standing or walking. Salpingitis, or chronic salpingo-ovariatitis, do not constitute a counter-indication, and in cases of chronic peri-uterine inflammation the bicyclette can replace with advantage the Swedish method of massage.

"Bicycling exercises, consequently, a healthy influence on the physical nature of women; they sleep better, digest better, their chest expands so as to find it necessary after a short time to enlarge the corsage of their robes. Mme. Sarrante concluded by drawing a vivid picture of the moral role of the bicyclette, the only physical exercise that husband and wife can take together."

Late Hereditary Syphilis.

Dr. Foster does not believe in what is often called late hereditary syphilis. He believes that in every case of inherited syphilis there are some symptoms during the first years of life, and in the vast majority of cases nearly 90 per cent. before the third month. These symptoms are frequently very mild and frequently escape observation, and the disease may then remain quiet until about the age of puberty. The lesions most commonly met with are of the skin, the eyes and the bones. —*Northw. Lancet.*

The Treatment of Jaundice.

Dr. M. Alivia, of Viterbo, read a paper before the International Congress on this subject, which concludes as follows:

1. Long-continued biliary stasis, comprising the secreting cells of the parenchyma of the liver and producing a certain anemia of the organ, markedly reduces and sometimes suppresses, the secretion of the biliary acids. The gravity of the phenomena described under the name of biliary intoxication does not, therefore, depend upon the action of these acids.
2. The scarcity or absence of bile in the intestinal canal modifies very seriously the chemical processes there taking place.
3. One of the most common of the gastric changes in icterus is the suppression of hydrochloric acid secretion.
4. There is little or no loss of carbonate of sodium in these cases.
5. The reaction of the contents of the stomach is usually alkaline, less often neutral or faintly acid.
6. The physiological activity of the bile and of the pancreatic juice of the intestine is retarded.
7. The chlorides in the urine are increased, the reaction of the fluid is often alkaline, there is diminution of urea with an abundance of products of the aromatic series.
8. The more marked are these characters so much the more grave are the disease and its clinical manifestations.
9. Alkaline treatment does not modify these conditions. The effect of the acid treatment is, however, to diminish the chlorides, to restore the normal acidity of urinary reaction, to increase the excretion of urea, and to reduce that of the aromatic products; at the same time there is a progressive increase in the weight of the body.

Ocular Headaches.

Dr. F. D. Green (*The Refractionist*) concludes an article on headache as follows:

1. Many cases of headache are due to ametropia.
2. Many cases are due to heterophoria.
3. Never pronounce a case as due to ocular strain until the nose is examined.
4. Inquire into the condition of the stomach.
5. In females inquire concerning the condition of the genitals and whether there is constipation.
6. Migrane may be due to ametropia or heterophoria, but frequently is not.

On the Value of Solanum Carolinense in the Treatment of Epilepsy.

In the presence of so chronic and incurable a malady as epilepsy, the introduction into medicine of any remedy which will diminish the number or the severity of the attacks in a certain number of cases is an improvement in our therapeutic measures which is not to be overlooked, and in solanum carolinense we believe such a remedy exists.

While we have not as yet administered it to a large enough number of patients to speak positively as to its therapeutic powers, in the few to whom we have given it it has given promise, which is, to say the least, encouraging.

Our attention has also been called to this subject by an article by Dr. Maxwell, of Indianapolis, in the *Indiana Medical Journal* in which he concludes that solanum carolinense materially controls epileptic seizures and is worthy of considerable confidence. Several of the observers quoted by Dr. Maxwell employed what is known as the succus solanum, but the preparation which we always used was the fluid extract made by Parke, Davis & Co., giving 10 to 15 drops of the drug three times a day after meals.

A Report of Cases of Chronic Heart Disease.

In the New York *Medical Journal*, Dr. R. H. Babcock, in reporting the results from employment of the Schott method of baths and gymnastics in diseases of the heart, says that the baths owe their efficiency chiefly to

free carbonic acids and the two salts of calcium and sodium chloride, while next in importance is the temperature, for as warm baths are debilitating and decidedly weaken the heart, even in health, they should in the beginning be from 92° to 93° F., and 87°, or a little lower, toward the close of the course of treatment.

The duration of each bath should be carefully limited, but may cautiously be prolonged with the progress of treatment and improvement of conditions.

One bath is given daily, but should be omitted every fourth day; the initial time is from five to eight minutes, to gradually reach a duration of twenty minutes.

A thorough course of treatment should extend through six or seven weeks, and after a rest of one month may be again continued if such be required.

The result of such treatment seems to lessen rapidity and increase the force of the heart's contractions, thus occasioning better filling of the great arterial system, with corresponding depletion of the engorged veins.

The gymnastics, which slow the rate and increase the force and volume of the pulse, should consist in flexion, extension and rotation of the extremities and trunk, but the attendant should carefully observe that the movements are made slowly and steadily, with occasional intervals of repose.

After referring to a number of cases successfully treated by this method, he concludes by saying that in those of aneurism, advanced anterio-sclerosis, acute softening or great fatty degeneration and degenerative changes of the blood vessels and myocardium, it is contra-indicated.

Value of Opium in the Laryngeal Stenosis of Children.

Dr. Carl Stern (*Ther. Monat.*) recalls the well-known fact that the difficulty in breathing in stenosis of the larynx in children is greatly aggravated by sleeplessness and fright. For this reason he has been led to treat these cases with opium, and his results have been so gratifying that he believes the remedy should receive more extensive employment. He uses it in cases—whether in diphtheria or without existing throat affection—in which the hoarseness, the barking cough, the stridor, the cyanosis, and finally the sucking in of the xiphoid process and lacteral portions of the thorax point unmistakably to stenosis of the larynx. He reports several cases in which the use of opium averted an apparently necessary tracheotomy. Stern gives from two to five drops of the tincture of opium, according to the age of the child and the intensity of the symptoms, the dose being renewed according to the result obtained.

The Best Treatment in Heart Disease.

Robert H. Babcock, of Chicago, Ill. (*The Journal of the American Medical Association*), concludes an able paper on the above subject as follows:

1. The position taken by Fraentzel, that rest is injurious in the treatment of all forms of heart disease is untenable, and the reasons he assigns are incorrect. Prolonged rest is detrimental, undoubtedly, in cases of enlargement of the heart without valvular disease, partly if secondary to arterio-sclerosis, and in cases of fatty or other degeneration of the cardiac muscles.

2. The cause, however, lies in the circulation outside of the heart and not, as stated by Fraentzel, in the liability of cardiac, like striped voluntary muscle, to degenerate as a result of prolonged inaction, since the heart muscle can not during life be subjected to complete repose.

3. When compensation has become destroyed in valvular lesions of the heart, particularly mitral stenosis and aortic incompetence, rest is indicated theoretically and is beneficial in practice.

4. Bradycardia would theoretically contra-indicate prolonged rest.

5. On the other hand, it is called for in paroxysmal tachycardia, but should not be maintained, after having shown its powerlessness to affect the heart rate.

6. Acute inflammatory or degenerative affections of the heart indicate rigid rest in the recumbent position.

Bicycling for Women.

The much-discussed question as to whether bicycling is *per se* an exercise suited to women is, perhaps, now of minor importance, since it has become fashionable, and will, consequently, be adopted by the gentler sex, without much regard as to its immediate or remote effects Its popularity is, however, a very satisfactory proof as to its capacity as a giver of health and pleasure, since it is not conceivable that the bicycle could ever have won its way, as did the corset, for instance, as a fancied adjuvant to physical charms. The late Dr. William Goodell, wise in an unusually wide experience, gave the exercise his unqualified endorsement, and from the almost entire absence of adverse criticism, it is apparent that the majority of gynæcologists are of the same mind. The whole question is an exceedingly simple one, and has been summed up by Dickinson (*American Journal of Obstetrics*), who concludes a very clear and complete paper upon this subject as follows:

Under proper conditions of costume and posture, with care that the exercise be gradually increased and properly graded for the individual case, and where there is no acute inflammation to contraindicate it, bicycling will probably show itself capable of large results as an agent in curing pelvic disorders, since it is one of the few exercises which attract women.

In view of women's disabilities and the disadvantages under which she has suffered in attempts to obtain interesting and beneficial muscular exercise, it seems hardly too much to say that the promise from the bicycle is far-reaching. Through it and the habits it will engender we look for better dress, freer dress, shorter dress in bad weather; for better exercise, for out-of-door activity, for steadier nerves, stronger muscles, painless periods, easy labors.

SURGERY.

Inhaling Chloroform.

Dr. A. Guerin, of Paris, (*Lancet*) says that death from chloroform may be avoided if inhaled exclusively through the mouth. When death occurs from stoppage of the heart, the cardiac muscular fibers cease to contract under the influence of a reflex action exerted by the nasal nerves on the pneumogastric, stimulating the inhibitory power of the latter on the heart. He further shows that when a rabbit is subjected to tracheotomy and then made to inhale chloroform directly through the trachea the drug has no effect whatever on the heart. On the contrary, when the chloroform is held before the nose of the rabbit, the heart immediately stops. The trachea being cut transversely, it is obvious that the chloroform inhaled by the nostrils cannot reach the heart through the bronchi. Dr. Guerin therefore assumes that the anesthetic agent exerts its injurious action on the movements of the heart through the intervention of the nasal nerves and the cardiac branches of the pneumogastric, the former acting reflexly on the latter. Dr. Guerin therefore advises that the nose of the patient should be held by the fingers until general anesthesia is produced, when there can no longer be any reflex action of the nasal mucous membrane anesthetized like the rest of the body.

The Danger of Apoplexy in Elderly Persons During Narcosis.

Senger, (*Deut. Med. Woch.*,) calls attention to the danger during the narcosis of elderly persons, and cites a case of a person of fifty-six suffering from sarcoma of the breast, but with healthy kidneys and heart, pulse normal but with sclerosed arteries. There was no undue excitement and but slight vomiting. Suddenly the face became deadly pale—the eyes fixed and expressionless, the pupils dilated and reactionless, the respiration shallow and gasping, the pulse could not be felt. The patient was finally restored by artificial respiration, heat, friction, etc., when it was found that had a partial hemiplegia of the right side. Two years later the patient had not fully recovered. The author believes this danger greater with ether than with chloroform, as arterial pressure is greater and longer sustained in ether narcosis, and hence he advises chloroform as the anesthetic of preference with elderly persons. Poffert reports a case of death after anesthesia in a previously healthy man of forty-six. The duration of the anesthesia was one-half hour and the amount of ether employed four and a half ounces. The ether was administered by Zerny's and lastly by Julliard's masks. The pulse was slow and regular, the breathing deep and rhythmical. Vomiting of mucus occurred during anesthesia and mucus rales were present at the end of the narcosis. The patient recovered consciousness quickly and there were no respiratory symptoms present for the first hour of the anesthesia. Then suddenly the breathing became difficult, loud, bubbling rales were heard and the patient coughed up a large amount of thick mucus. The pulse remained normal, the patient was perfectly conscious and it was thought to be only an excess of salivary secretion. The patient became worse despite the injection of camphor, the heart's action became feeble, he became cyanotic and died with symptoms of pulmonary œdema two and a half hours after the end of the anesthesia. The post mortem made the same day showed enormous œdema of the lower lobes of the lungs, which the author characterizes as post ether narcotic œdema of the lungs. Death during anesthesia is less frequent with ether than with chloroform, but the late deaths are more frequent with ether. The statistics collected up to the present time (*i. e.*, Guilt's) have not established the claimed superiority of ether over chloroform.

Cancer of the Breast—Operative Procedure and Statistics.

Halsted, of Baltimore, lays down this rule: "The pectoralis major, entire or all except its clavicular portion, should be excised in every case of cancer of the breast, because the operator is enabled thereby to remove in one piece all the suspected tissues.

The suspected tissues should be removed in one piece (1) least the wound become infected by the division of tissues invaded by the disease, and of lymphatic vessels containing cancer cells, and (2) because shreds or pieces of cancerous tissue might readily be overlooked in a piecemeal extirpation.

". . . Now . . . we regularly clean out the infraclavicular, and usually the supraclavicular region, and remove a part at least of the pectoralis major."

He calls attention to the hopeless attitude assumed to the disease by members of the profession who had been accustomed to the old procedure, in which the breast only was removed. "The younger Gross did not save one case in his first hundred. Dr. Hayes Agnew stated in a lecture shortly before his death that he operated on breast-cancer solely for the moral effect on patients."

"Encouraged by rare but positive cures, German surgeons, led by Volkmann, have for many years been earnestly at work on this problem."

Taking Volkmann's standard of three years' immunity as the guage of radical extirpation, the best results are as follows: Bergmann, 30.2 per cent.; Billroth, 4.7 per cent.; Fischer, 9.0 per cent.; Gussenbaur, 16.7 per cent; Konig, 22.5 per cent; Kuster, 21.5 per cent.; Lucke, 16.2 per cent.; Volkmann, 14.0 per cent.

Of 50 cases operated on by Halsted after the manner set forth—

In 5 details are not obtainable.

In 3 only has there been local recurrence, that is in the scar, apparent or buried.

In 8 there has been regionary recurrence (skin or supraclavicular glands).

In 34 there has been no recurrence, local or regionary, these dating from 2½ years to two months, so that he is not yet in a position to compare his statistics with those already quoted.

No patient out of 50 died of the operation.

Ureterotomy.

Dr. Kelley (Johns Hopkins *Hospital Bulletin*) refers to three cases in which he resorted to this novel operation for the purpose of ascertaining the permeability of the ureter. The operations were for myoma uteri, carcinoma uteri and dense pelvic inflammatory disease. After the completion of the operations there was a fear that the ureter had been included in the ligature, as in each instance it appeared to be enlarged. To release a large number of ligatures and expose the patient to the risk of hemorrhage, or to perform catheterization of the ureter would have been impracticable. He therefore located the ureter at the pelvic brim, snipped the peritoneum over its course, and made a longitudinal incision one-half cm. in length into the lumen, through which he passed a small ureteral sound into the bladder.

In two cases the ureters were found so be free, the enlargement being due to the pressure of the pelvic mass previous to the operation. In the third case the ureter had been encluded *en masse* with a large area of bleeding tissue in the pelvic floor. After the removal of the ligature the sound passed easily into the bladder. By this simple operation much time was saved and all three cases had uninterrupted recoveries. For closing the slit in the ureter he used the delicate mattress suture in two cases. Third required four sutures on account ot the persistent oozing of the urine. These sutures are very lightly passed into the outer coat of the ureter, not entering its lumen.

Retro-Displacement of the Uterus.

Malpositions of the uterus are difficult to treat and require skill and patience. Dr. Alfred C. Carpenter, in speaking of retro-displacements of that organ in the *American Journal of Obstetrics*, advises never to attempt to replace a retro-displaced uterus with the patient on the back.

If the pessary fails, the operation of hysterorrhaphy may yield good results. Another method if that of shortening the round ligaments. A third method is called by Dr. A. P. Dudley of New York, desmopycnosis. The objects attained by this operation are three-fold:

1. It shortens the round ligaments without sacrificing any of them, sufficiently to hold the uterus in a position anterior to the perpendicular line of the body, by simply changing their point of uterine attachment and including with them the anterior fold of the broad ligament, across which the round ligament passes to reach the inguinal canal.

2. Denuding and firmly fastening the round ligaments to the anterior surface of the uterus thickens and gives extra support to the latter.

3. By this procedure you succeed in maintaining the uterus in a normal position without fastening any portion of it to the anterior abdominal wall.

Dudley claims the following advantages for this method over either hysterorrhaphy of the Alexander operation.

1. It corrects the displacement by utilizing the natural supports of the uterus without sacrificing any of them.

2. The proper diaphragmatic action of the pelvic floor is not interfered with.

3. The bladder is not imprisoned in the least and its proper action is undisturbed.

4. There is no chance for intestinal adhesions about the line of sutures, for the latter lie in apposition to the posterior surface of the bladder, and adhesions taking place at this point simply elongate the utero-vesical junction.

5. In case of impregnation the uterus is free to rise in the abdominal cavity.

6. The use of catgut as a suture material in the operation does away with the danger of the formation of sinues by the ligature.

Fibroids and Conception; Pregnancy and Labor.

Dr. Hofmeier (*Zeitschr. f. Geburtsc. u. Gynak*) in a very complete and well-tabulated essay denies that fibroid disease of the uterus has any direct influence in causing sterility. Statistics do not show that, as has been alleged, subserous myoma predisposes considerably to sterility, whilst polypi and myoma of the cervix have little influence in that direction; nor can it be shown that fibroids promote sterility. These tumors seldom begin to appear till late in sexual life, so that if the patient is barren or a multipara the causes of her sterility or fecundity must have influenced her long before the development of her fibroid. The alleged frequency of this disease in elderly virgins is based on a fallacy. It is the local affectation which the most readily drives a spinster to the gynecologist, whilst middle-aged married women trouble less about small and slow-growing abdominal swellings. Women with fibroids who marry late in sexual life are fairly fertile, though Hofmeier can hardly make out cause and effect in this fact. Fibroids by no means strongly predispose to abortion. It seems that this accident happens only when the uterine cavity is rendered unfit to bear through the size and relations of the tumor; nor does fibroid greatly interfere with the uterine contractions during labor. The best time for hysterectomy is not immediately after delivery, but a few weeks or months later.

NEWS AND MISCELLANY.

The Buffalo Medical Journal

Will be fifty years old in a few weeks. The editors propose to signalize its semi-centennial anniversary by increasing its reading pages from 64 to 80, and by making other improvements that will contribute to its efficiency and keep it abreast of the professional progress of the period.

There are very few medical journals in this country that have reached the age of fifty years, and THE REPORTER extends its heartiest congratulations and cordial good will to a contemporary which after fifty years has not passed the prime of life, but with renewed spirit promises to be still young when it rounds out its century.

ORIGINAL ARTICLES.

DIPHTHERIA AND ITS TREATMENT.

HIRAM CORSON,* M.D., PLYMOUTH MEETING, PA.

My ear is pained, my heart is sick with each day's report of the fatality of this disease. Two, three, four, five children lost in a single family. Last week five were carried away from one home. How unspeakably sad to loving parents.

In conversation with medical men, and from the writings on this subject which appear in medical journals, I believe that very few physicians have any principles of treatment, but proceed to treat the disease by means of small or large doses of medicine, said by some author to be "good for diphtheria." Some new coal-tar product, perhaps, with a reputation of only a month or two; spts. nitre to cause perspiration; or a quarter or half grain of calomel given every hour, which some one has told them he believes the best, most efficient, constitutional remedy that can be used. In a day or two, as he has no principles of treatment and his patient grows worse, the physician becomes confused, looks through this and that medical journal, finds some remedy recommended as being very "good in diphtheria," and tries that. As the case rushes on, despite his efforts, he falls back for comfort on the fact—as he deems it—"that a certain number of cases will die, in spite of the best treatment." After this conclusion, he merely tries this or that medicine, which some one has recommended, "to see what it will do," though he himself has had no experience with it.

There are a few things indispensable for the treatment of any disease: (1) to discover what is the matter—in other words to diagnose correctly; (2) to establish true principles of treatment; (3) to seek for and apply the measures in accordance with these principles of treatment.

Within the past few years, a physician writing on pneumonia gave a most accurate description of the condition of the system in the various stages of the affection, after which he announced his principle of treatment, viz.: "The pulse must be kept below eighty beats per minute." That was all he aimed at. To do that he used Verat. viride steadily; pushed it as close to the line of danger from its own poison as possible. Though his measures were, perhaps, not the best, yet they were in accord with his principle, which was in fault.

Sixty years ago, malarial fevers, called bilious fevers, were abundant, and the principle of treatment was to heat the system, cause profuse sweating, and thus carry out of the system the special poison which caused the disease. The principle of counter-irritation to allay certain local sufferings, as violent headaches, sickness

*Ex-President Pennsylvania State Medical Society; Associate Fellow College of Physicians; Associate Member Philadelphia Obstetrical Society; Honorary Member International, Gynecological and Obstetric Associations, etc., etc., etc.

of stomach, etc., was carried into practice by the application of large blister plasters kept on the surface of parts of the body for the space of twelve hours, then poultices or wilted cabbage leaves applied for days to continue a purulent discharge. Hot teas and heavy bedclothes were also applied to continue the sweating. Not a drop of cold water for drink.

So I might recall several principles of treatment, but all this has been merely preparatory to my real object—the presentation of the principles of treatment in diphtheria, scarlet fever, measles and some other inflammatory diseases; also, the means to be used successfully in accordance with these principles.

Some of you have doubtless learned from my writings how I was led, sixty-six years ago, to rebel against the principle of treating measles and scarlet fever by heating the system by means of hot teas, warm bricks to the feet and alongside the patient in bed, excess of bed clothes, and to substitute other measures for relief in accordance with my principle that the *heat of the body in those diseases should be subdued;* and that the most pleasant and, by far, the most efficient means of effecting this was the application of cool or cold water over the surface of the body by sponging and on the head by affusions of the cold water.

Such was the principle of treatment advocated by me sixty years ago, and cold water the means by which the principle was carried into effect; and now, though I join with those who sometimes doubt the veracity of one who, in advocating a certain mode of treatment, says, "I never lost a case," yet it is incumbent on me, now and here, to say that in all those years, from 1829 to this day, not one of the many hundreds of cases of measles, etc., treated by the cooling system, under my care, proved fatal. Yet, even within a few years I have known, both in city and country, children to be lost under the hot treatment.

My position, when defying the old heating treatment so universally believed in by parents and physicians, and in its place substituting a treatment based on the very opposite principle—the use of *cold* drinks and *cold* water applications to the heated body—was not a pleasant one, especially when physicians of many years' experience in practice, denounced my mode in most positive terms as imperiling the lives of my patients. Indeed, had I lost only one or two of my earliest cases, I think I would in all probability have been prosecuted for criminal malpractice. I was so young, so inexperienced in practice, had no precedent to support me, that now it seems to me I was in a perilous situation. But thanks to a kind Providence, I escaped; my patients all recovered; all were happy, as were the parents, under the treatment.

Two years afterward, when an epidemic of scarlet fever occurred, I regarded the same principles of treatment applicable, and when, on or about 1850, we were confronted with a disease—diphtheria—which in its severest forms seemed the counterpart of what we had been used to call "malignant scarlet fever," or "putrid sore throat," I regarded the proper principle of treatment to be the same as in the two other diseases, and that the cold treatment was demanded for the safety of the patient.

I have so repeatedly given my views in relation to scarlet fever and diphtheria that I need say nothing more on these subjects than that, having carefully observed what has been written on other modes of practice and having seen their fatality, I am constrained to say, after so long and vigilant a practice, that there is no other mode of treatment in vogue which at all equals, for comfort to the patients and their speedy and successful restoration to health, that of *reducing the heat* of the body by the judicious application of cold water in the various ways in which it can be applied; and aided, too, by the topical application of ice, when that is needed, to allay the inflammation of the tonsils, sub-maxillary glands and the inflammation of the laryngeal and tracheal mucous membrane in cases where these are so affected as to cause croup. And here I may say that this croupy condition, though one considered almost certainly fatal when occurring in diphtheria, is quite remediable under the proper and persistent application of ice to the front of the trachea, prior to the formation of much diphtheritic membrane. In other words, applied on the first announcement of the croupy cough or voice. In my own practice I had but two very bad cases, and both yielded to the continuous application of pounded ice,

with just sufficient water to bring the ice and ice water in close contact with the fore part of the larynx and trachea, and kept steadily there night and day until the inflammation is subdued. All have heard the reports by practitioners of its great value in ordinary croup. Nor is it strange that it should bring relief. It is impossible for the inflammation to extend under its application. You start at the assertion that it is impossible, and yet it is true.

In 1853, I was called to a woman a few days after the birth of a child, and found her suffering greatly from an inflammation of the left mammary gland. It was swelled, tense and fiery red. I proposed to cover it with cloths wet with ice water and to be renewed every few minutes. She feared a chill, but finally consented. Finding it most grateful, the heat and burning sensation reduced and the pain much abated, she kept the nurse steadily at work applying the cold water cloths.

As the relief was so decided, I procured a bladder; half filled it with small lumps of ice and enough water to form a cushion which would closely fit the whole breast. A few hours showed me that the danger of suppuration was averted. From that day until I ceased to practice a few years ago, I used the ice in every case presented to me, and always with immediate comfort to the patient and instant arrest of extension of the inflammation.

About forty years ago, I was called to a child, aged about one year, ill with scarlet fever. The glands and the tonsils were so swelled that it could not nurse. It was in a pitiable condition. I told the mother I had never saved so young a child in that condition, but if she would let me apply ice to the swelled glands, I thought it could be saved. She assented. Lumps of ice were lapped in two thicknesses of old wet muslin and held in place by the "helps" all night. There was striking relief. In a few hours the child could swallow and it was evident from its quiet condition that the remedy was most agreeable. The means were continued, and in a few days the little patient was well.

From that day to the present time, in scarlet fever and in diphtheria, when the tonsils and subjacant glands were inflamed and greatly swollen, I have used ice freely and with gratifying success.

Wherever inflammation exists in a part accessible to the ice, as in the cases named, as well as in pleurisy, peritonitis, pneumonia, and in traumatic inflammations, it can be held in check—utterly subdued—by the proper use of ice.

I may only call attention to the valuable results produced by the cold treatment of typhoid and other fevers. In the hospitals of Germany the death rate has been reduced to one per cent. In this country the cold treatment, as used by Brand in Germany, is equally successful, and is becoming common practice in hospital and even in private practice.

I must close, though with your permission I will be glad to add a few words, as it is not probable that I shall ever again speak on this subject.

Is it true that for sixty years I successfully treated every case of measles under my care, by the use of cold water to reduce the temperature of the body?

And that for almost sixty years I used the same means to allay the excessive fever so common in scarlatina? And that since 1850, I have used the cold treatment in all cases of diphtheria with, as I believe, much better results than those obtained by others with any other kind of treatment? And is it true, as I declare it to be, that this most efficient means of reducing the abnormal heat of the system and the consequent suffering of the patient, does not exclude the use of medicine to aid in the treatment? Or have I given false testimony? Is it true that typhoid fever, for the last half century so greatly dreaded and so fatal, has been by the cold bath treatment of Brand, reduced to one per cent. mortality; and is now, in our county, in both hospital and private practice regarded as the best mode of treatment, not only in the disease named but in all febrile conditions; or have the eminent men why have reported on the subject, done so falsely?

It we have all spoken truly, why shall not our physicians of to-day resort to this means of reducing the fever and discomforts of the suffering patient, inasmuch as the cooling treatment does not preclude the use of their favorite medicines?

Should they do so, I feel confident that we would never again see three or more children swept, in a single week, from one family, as has so frequently occurred this past winter in the region around, under the treatment in vogue.

But I am confronted by reports in medical journals in which the writers state that they have tried the cold or cooling treatment in diphtheria and even in scarlet fever, and did not find it efficient. I can readily believe it. Many have made such reports and the reports have been placed on record. But there are also many scattered over this State and over our whole country, who give strong testimony in its favor. The objectors to it are those who have never used it, and those who prescribe for the *name* diphtheria and not for the disease itself. To them the affection of the nervous system, sickness of stomach, inflammation of the tonsils, submaxillary glands, the pharynx and larynx, signify nothing. They have a treatment "good for diphtheria." Enough for them to know.

But there are some who have tried the cooling treatment with a desire that it should succeed, but who did not find it so efficient as had been reported. There are many honest reports of this kind, and the hopes of success were defeated by the inefficient application of the means by those in attendance on the patients. We well know that if the cold water and the ice be not in close contact with the inflamed, heated part it cannot have an effect to subdue the heat or allay the inflammation. Take for example a highly inflamed breast; hold the ice but the width of a knife-blade from it and it will be found utterly useless, as useless as if put around the bed-post. Many physicians have been thus deceived. Unless the most positive directions be given, and the nurse shown how the means should be applied, failure must result.

In the application of the ice to the swelled and inflamed tonsils and glands, and to the fore part of the neck when a diphtheritic exudation is taking place in the larynx and trachea, the ice should be mashed and closely fitted to the part affected. Often have I seen the bladder or cloth holding the ice, hanging an inch or two, or even more, away from the parts affected, instead of being closely fitted to them. The physician cannot stay all the time with the patient, and the nurse, regarding the ice not as the treatment but as merely an aid to the medicine, gives it but little attention.

I am desirous to reach the truth on this subject; to know whether the present fearful mortality is owing to the present erroneous belief that the fever is due to the increased activity of the heart, and the principle of treatment is to subdue the fever by the use of arterial sedatives—the treatment which results so disastrously.

Whatever may be the cause of the fever, whether the little entity called microbe (millions of which are always with the healthiest of us), or any other cause, we know that the fever is the cause of the increased action of the heart, and that there are no means of reducing the high temperature—the fever—so efficient as the application of the means to which I call attention, and which I have tested for more than half a century.

In the hope that a treatment less fatal than that now in use will soon prevail, I leave the subject with you.

Empress Carlotta's Death Caused by Poison.

According to a story now going the rounds of the press, and credited to "Gen. Rudolfo Gunner, commander of Maximilian's body-guard during his brief and troubled reign as emperor," it was not adversity that drove his empress insane. She was poisoned by an old Indian woman who had been hanging about the palace begging alms, and in this way gained the opportunity of giving her the decoction of *talavatchi*, a poison described as "more dreadful in its effects than anything in the sinister pharmacopeia of the medicis." Given with skill, it kills the mind and leaves the body to live on unimpaired. In large quantities it produces hallucinations, followed by unconsciousness and death. The *talavatchi* given the Empress was judged to a nicety. It wrecked her mind, but left her body healthy. Outside of flowers the world to her does not exist. The love of home, country and friends passed away after the draught of the Indian witch's decoction.

"The administration of this poison," says General Gunner, "formed one of the sciences of the ancient Aztecs. Their descendants, who are the peons of Mexico, have preserved the knowledge, and in their hands it becomes a dangerous and subtle weapon. It can be given in coffee in small quantities day by day, and the victim will gradually become insane or an epileptic, or both."—*N. Y. Med. Times.*

TRACTION DIVERTICULUM OF THE STOMACH COMMUNICATING WITH THE PANCREATIC DUCT.*

HEINRICH HEUBEL, ERLANGEN, GERMANY.

The case reported is one of Professor Bostroem's, observed at Erlangen in 1878, and is published by permission.

The well-known studies of Von Zenker have shown that traction diverticula of the œsophagus begin with an inflammation of some extra-œsophageal tissue, usually a lymph node, which becomes adherent to the œsophagus. The subsequent cicatricial contraction almost inevitably produces a pouching out of the œsophagus, since the inflammatory mass is usually firmly anchored to other deeper tissues. The same process may occur with other hollow organs, especially with the intestine on account of inflammation of the gall bladder, with resulting fistula.

Although the lymph nodes lying behind the stomach and the pancreas lying beneath it, might, *a priori*, be expected to produce the same lesion of the stomach, the following case is the only one which the writer has been able to find reported.

The patient had been confined for a few weeks at the District Insane Asylum at Erlangen. For twelve years, he had been excitable and anxious and had suffered from insomnia. These symptoms had been exacerbated by an attack of erysipelas of the head two years previously, and had increased notably in the last year of his life. The patient was kept in bed with difficulty, and was always unclean in spite of the precaution of placing him frequently on the commode. He took only liquid nourishment and would spit out all solid food, especially meat. He was very thirsty and drank soup containing egg and a cognac mixture eagerly. After a brief improvement had set in, the patient again had an appetite for bread, though he digested it slowly; but always had an antipathy to meat. Collapse, with tracheal râles, occurred suddenly while the patient was on the commode, and death resulted in a few hours.

On section, there was found considerable hyperostosis of the skull; marked hyperæmia of the brain, with thickening and cloudiness of the meninges; chronic hæmorrhagic pachymeningitis of mild grade, and chronic hydrocephalus. Hyperæmia and œdema of the lungs, which were decidedly emphysematous, and bronchial catarrh were, apparently, the ultimate causes of death.

From the third to the eighth rib, on the left side, there was an old united fracture with a cushion-like thickening on the inner side. The fractures were almost in line, two or three centimeters from the attachment of the cartilages. The left lung was adherent to the costal pleura in the greater part of its extent. The mucous membrane of the throat was pale; that of the œsophagus, in the lower half, was somewhat congested venously, and was beset with numerous little warts.

The stomach was contracted and contained only a little watery fluid with flocculi of mucus. The mucous membrane was covered with an abundance of soft grey mucus, was slightly injected, was finely mammillated (*gewulstet*) and thickened, and, in the neighborhood of the lesser curvature, on the posterior wall, it was quite coarsely mammillated. The submucosa and especially the muscularis, were so thickened that the whole organ felt stiff. About the middle of the lesser curvature, somewhat more toward the pylorus and the posterior wall, was a funnel-shaped diverticulum of the mucous membrane, whose opening into the cavity of the stomach had a diameter of five or six mm. The thickened and puckered, but nowhere cicatrized mucous membrane, was gathered into exquisite folds. Through this opening into the fistulous canal, a probe passed obliquely to the right, posteriorly and superiorly, to a depth of four cm.

After careful preparation, the diverticulum showed on the outside, a beautiful infundibular prolongation of the stomach wall, one cm. in length, the apex being

*From the German Archives for Clinical Medicine, Volume 55. Translated by A. L. Benedict, A.M., M.D., Lecturer on Digestive Diseases, Dental Department, University of Buffalo.

firmly united with the pancreas. The outer, longitudinal muscular fibres were sharply defined at the neck of the diverticulum, but did not extend farther; the internal circular fibres, on the contrary, extended to the apex of the funnel where it was adherent to the pancreas. With the probe one could easily penetrate through the diverticulum and into the pancreas, reaching what proved to be the pancreatic duct.

The pancreas was strikingly deformed. Though of normal length (20 cm.), it was slender and flaccid, and measured in breadth 2 cm. at the tail; 1.5 cm. in the middle, and was only 5 mm. in thickness. At the head it was irregularly bossilated. Except at the latter part, which will be described subsequently, it was extremely flabby. In the center was to be felt a tough cord. At both sides of this a number of firm, elastic kernels of various sizes, up to that of a small pea, were palpable. The parenchyma consisted of very soft and flaccid discoid lobules, loosely attached one to another. On section most of these were shown to be encapsulated masses of adipose tissue; a small number consisted of pale gray and flabby parenchyma. The firm, elastic kernels which were scattered in the tissue like shot, revealed, on section, little gelatinous bodies (literally corks), which left behind smooth-walled cavities of corresponding size.

On incision, the cord which was palpable in the midst of the pancreas, proved to be the duct of Wirsung. In its peripheral part, 11 cm. length, in was considerably and pretty uniformly dilated, measuring 12-13 m.m. in diameter. Its wall was greatly thickened, up to 1 m.m. It was very stiff; the inner surface was opaque, cloudy, pale-gray but perfectly smooth. The mouths of tributary ductlets were not expanded; for the most part they were contracted or closed. The cavities filled with gelatinous matter, already mentioned, could not be emptied into the pancreatic duct by pressure. After the course of 11 c.m., the duct of Wirsung became again narrower toward its mouth, and here, for 3 c.m., its breadth was only 7 m.m. Its wall, however, was still more markedly thickened, and the inner surface was not only thickened and opaque, but lined with irregular white scars. Between the wider and the narrower portions of the pancreatic duct, to the right and upward, there was a slit-like fistulous opening, 5 m.m. long and 1 m.m. wide. Into this extended shining lines of scar tissue from the inner coat of the pancreatic duct. Through this opening the probe passed immediately into the adherent gastric diverticulum.

On the farther side of its narrower and scarred portion, the pancreatic duct again became quite suddenly broader and, for a length of 2 c.m., it had a diameter of 17 m.m. By pressing on the surrounding tissue a clear, thin mucus was forced out from the finer branches of the duct. From this part of the duct, a cavity of the size of a hazel nut was reached, surrounded on all sides by the thickened pale-gray, cloudy, opaque, moderately smooth, scarcely cicatrized and, in part, finely papillary mucous membrane of the duct. Around this cavity was tough connective tissue, enclosing above a completely isolated cavity as large as a cherry pit. From this was evacuated a clear mass of mucus. The inner wall of the cyst was unevenly villous.

Around the cul-de-sac of the duct of Wirsung, involving the head of the pancreas and fitting into the concavity of the duodenum, lay a tumorous mass, tough and almost as large as the fist. This consisted of numerous tense cysts, thickly crowded together, and varying from the size of a pin-head to that of a hazel nut. These were uniformly filled with clear transparent, gelatinous matter, and limited by a very thin, smooth, translucent membrane. The intervening structure was of tough connective tissue. After evacuating a large number of the transparent masses, the tumor had visibly decreased in size, and there now remained larger cavities with similar contents, connected with the pancreatic duct, especially with that part of it which had undergone cystic dilatation. Through the latter, the probe led through an opening 1 cm. long, 2 mm. wide, into a cavern 22 mm. long and wide, and 7 mm. in height. This was almost entirely filled with a mass of mucus, partly clear and translucent, partly whitish and opaque. The wall of this cavern was very uneven, marked in spots with greyish-white scars, and presented numerous mammillations. The wall of the pancreatic duct ceased at the entrance to this cavern with a sharp scar-like line of

demarcation. From the cavern there was an immediate communication through a round opening as big as a pea, into the beginning of the lower, transverse portion of the duodenum. From an upper pouch of this same cavity, the probe passed also into the descending portion of the duodenum, emerging in the vicinity of the mouth of the ductus choledochus.

From the cystic dilatation at the end of the pancreatic duct, there was a passage, nearly in line with the duodenum, into a cavity the size of a cherry, which was distended with thick mucus and lined with a membrane grayish-white and slate colored. From this, through a hole the size of a cherry-pit, there was a passage into the desceuding portion of the duodenum. From the same cavity there were three other passages into the duodenum; the first leading into the the duodenum at the junction of the superior transverse and the descending portions; the second, into the superior transverse portion; and the third into the same about 1.5 cm. from the pylorus.

The part of the duodenum involved, 6 cm. in length and 3.5 in breadth, was driven upward by the tumor, and was covered with very adherent, soft, clear mucus. After cleansing this away, the mucous membrane appeared everywhere pale, and the surface was very uneven on account of the pressure of the tumor. The mucous membrane extended to the bottom of the depressions, and here were found the various fistulous openings already described. From this side they appeared still more numerous. Some were pervious for a coarse probe; some, for the tip of the little finger. The mucous membrane passed pretty deeply into some of the broader openings, and was sharply demarked from the cicatricial tissue that took its place. Immediately beneath one of the wider fistulæ, the ductus choledochus opened. This duct was dilated in its whole course up to a diameter of 2.5 c.m. · Its wall was otherwise normal and soft.

All these numerous small and large fistulous openings, which were found from the immediate vicinity of the pylorus to the lower transverse portion of the duodenum, were closed by a dendritic growth of vascular villi. The villi were over a centimeter long; some slender, others broader. Laying these back, the fistulous openings became visible, and it appeared that the villi surrounded the margins of the fistulæ like a wall, and, in places, even grew from the mucous membrane that extended into the fistulæ. The exuberance of villi seemed to be limited to the area of fistulous openings. In the descending portion of the duodenum, however, where several fistulæ were located along with the opening of the ductus choledochus, there were greater superficial expansions of villi, and more careful examination showed that the mucous membrane between the fistulæ was much undermined and elevated into bridges, and that, in such places, finer fistulæ opened into the larger ones.

The entire lymphatic system in the neighborhood of the pancreas, was normal.

The gall bladder was distended with thin, pale, orange-colored bile, in which were swimming a number of soft, compressible, brownish concretions.

The liver was atrophic but otherwise normal.

Common Membranous Sore Throat.

The correctness of the position taken by Professor J. Solis-Cohen, Sir Morell Mackenzie and other authors, as to the existence of *membranous sore throat, not diphtheric in character*, has come to be universally admitted, and the claims advanced for certain methods of treatment in diphtheria proved to be based upon erroneous diagnosis. A recent illustration of this fact has come under notice at the Laboratory of Bacteriology, where cultures from three cases of membranous sore-throat, much resembling diphtheria in appearance, in two of which there was high fever accompanied with constitutional depression, proved to be free from Klebs-Loeffler bacilli.

Hemoptysis.

For the medicinal treatment of hæmoptysis, in pulmonary tuberculosis, Prof. S. Solis-Cohen prefers calcium chloride to any other drug.

The pure crystalized salt is specified on the prescription, so that chlorinated lime shall be dispensed. It is given in glycerin or simple elixir and water, or in infusion gentian, 10 grains to the teaspoonful; the ordinary dose in the active stage of the hemorrhage being 10 grains or 15 grains every second hour. As improvement takes place the frequency of administration is reduced.

AN HISTORICAL SKETCH OF DIABETES MELLITUS.

CHARLES B. WILLIAMS, A.B., M.D.,* PHILADELPHIA, PA.

Diabetes was one of the few diseases that was distinctly recognized and described by the ancient fathers of medicine. Some of the various names under which it has been described in the classics are quite curious, viz.: *Hydrops matellæ; profluvium urinæ; fluxus urinæ; morbus sitibundus; diarrhœa ad urinas; dipsacon;* etc., etc.

Hippocrates makes no mention of the disease in his works, but Theophilus, Actuarius, Aretæus, Aetius, Trallianus, Avicenna and Galen, besides many others, have written largely upon the subject of diabetes.

Now comes the question whether many of the cases mentioned by the classic writers were true cases of diabetes. There can be no doubt that some of the cases described were true cases of diabetes mellitus. Let any one read the description of this disease given by Aretæus and he will marvel at the pen picture that this great observer has made. Of course, Aretæus was describing a case of true diabetes and giving all of its symptoms, which were the same then as now, without being aware of the saccharine nature of the urine, for this was a fact that was discovered centuries later. And such must have been the case with all the writers who preceded and followed Aretæus up to the time of Willis, the discoverer of the true diabetes mellitus, in the time of Charles II.

A number of the cases that have been described are, indeed, doubtful cases of true diabetes. Scribonius mentions a case where the quantity of urine passed by a patient was four times the quantity of liquids that was ingested. The case published by Sir Kenelm Digby, of the nun at Rome, who for some weeks passed more than two hundred pounds of urine in every twenty-four hours, must be taken *cum grano salis.*

Galen, Lib. vi. aff., cap. 3, states that he saw diabetes but twice. Diabetes as Riverius knew it, "is a quick and plentiful sending forth of drink by urine; after which there comes a violent thirst, and consuming of the whole body."

As stated above, Dr. Thomas Willis, who lived in the time of Charles II., was the first physician who positively noticed the saccharine nature and honey-like taste of the urine in the true diabetes.

Van Helmont, long before Willis's time, had said that the blood of a diabetic patient is changed to a whey-like urine. "Atque in diabete totus cruor mutatur in lotium lacteum."

Sydenham says:* "It sometimes happens, though very rarely, that the aged, after having been long afflicted with an intermittent, and weakened by improper bleeding and purging, are seized with a *diabetes,* though the intermittent be perfectly cured."

Dr. Cullen also found saccharine urine after a long fever in an old man.

Mr. Morton has given the case of a master wheeler, whose father had lost all of his male children with a consumption following a discharge of saccharine-tasted urine during dentition. Guidott, while he was a student at Oxford and only eighteen years of age, attributed the saccharine nature of diabetic urine to an imperfect assimilation of the chyle.

The following are some curious cases of diabetes collected by Dr. Thomas Girdlestone, A.D. 1799: "Avicenna remarks that the eating of quinces brings on diabetes. Dolaeus relates the case of his uncle who, in one night's time, brought on a diabetic discharge by the drinking of cider. John Baptist: Theodosius says he had seen the true diabetes only in two women, which disease they had induced by the abuse of Roman wine. Dr. Home knew the chylous species of diabetes 'brought on by too frequent doses of jallap et mercur dulc.'"

Dr. Falconer observes that the Japanese are subject to diabetes and atrophy from the use of tea, and that he knew a man who induced a diabetes by the drinking of spruce tea. Mr. Charles Darwin thought that diabetes was caused by the retrograde

motions of the lymphatics from their valves being diseased. Dr. Rollo thinks, "a morbid condition of the stomach, and a general diffusion of saccharine matter, with probably some change from that of health in the fluids of the system, are the immediate causes of diabetes."

Dr. Benjamin Rush, when asked by William Washington of Alexandria, Va., a student at the University of Pennsylvania who was about to prepare a thesis on diabetes, what his theory of diabetes was, replied:—"Diabetes consists in a morbid or irregular action in the whole sanguiferous system, or in other words, it is a state of fever accompanied with a local determination to the kidneys. This is evinced by its being attended with all those symptoms which are usually the consequence of other febrile states of the system; viz.: pain, increased action of the pulse, thirst, increase of heat, and a flushed countenance. These are all inseparable from it, and it must be acknowledged that they are the effects of febrile action." In all of the cases of diabetes that Dr. Rush attended, the pulse was found to be full, tense and quick.

Diabetes mellitus, as we now know it, is essentially a chronic affection, and a disorder of nutrition characterized by the constant presence of grape sugar in the urine and the blood; added to which there is an excess in the urinary discharge, together with the progressive loss of flesh and strength.

COMMUNICATIONS.

THE PSYCHOLOGICAL ASPECT OF HYPNOSIS.

WM. ROMAINE NEWBOLD, PH.D.,* PHILADELPHIA, PA.

The theories, psychological and physiological that have been proposed to account for hypnosis, are very nearly as numerous as the theorists, and not one has met with universal acceptance. Yet we are by no means relieved of the responsibility of framing hypotheses. Scarcely ever has a great scientific generalization been established that was not constructed out of the ruins of a thousand hypotheses, and unless those thousand hypotheses had been devised, tested, and successively found wanting we would never have had the material out of which to construct the true explanation. It is in this light that I regard the theory which I shall advance.

It is based upon the facts of hypnosis chiefly as observed and reported by the school of Nancy, which my own limited experience has in every respect confirmed, and is most nearly akin to that of Dr. Despine. It is an effort to bring the facts of hypnosis into line with the psychological doctrine of the dynamic mental state; a doctrine, which was, I believe, first taught clearly by Herbart, but for which a satisfactory scientific foundation has been but recently supplied by the researches of neurologists into the functions of the cerebral cortex. Scanty and disputable as our knowledge on these points is, there is a substantial agreement between the main results of introspective observation on the one hand and clinical observation and direct experiment on the other, which is exceedingly encouraging.

One will readily understand that within the limits of this paper I can do no more than state and make plain the leading features of the tentative theory upon which I am now working. It is a theory that brings the chief phenomena of hypnosis into harmony with fundamental psychological principles and with the fundamental principles of cerebral physiology as far as I understand them, but which must undoubtedly suffer extensive modification as our knowledge of mind and brain progresses. I shall, however, in concluding, point out some of the dangers attending the practice of hypnotism and say a word as to the relation often supposed between hypnotism and telepathy.

It has long been known that certain in-

* Lecturer on Philosophy, University of Pennsylvania.

dividuals can be put, by the use of definite agencies, into a condition closely resembling sleep, but differentiated from it by sundry traits. These agencies are numerous, but all agree in involving the checking of the train of ideas, the restriction of attention to one idea or sensation, or to a constantly recurring but narrowly limited series of sensations, such as is given by passing the hands before the patient's eyes, by light touches or stroking, by rotating the head upon the shoulders, and so on. After the lapse of a time that varies in different individuals from a few seconds to thirty minutes or more, phenomena closely resembling sleep supervene. The eyelids become very heavy; they close; the field of consciousness becomes narrower and narrower, wanes and finally disappears. When the patient awakes, he believes that he has been asleep. But we can show that he has not been asleep in the ordinary sense of that word. He is nearly always cataleptic; his limbs tend to retain any position impressed upon them by the operator. He appears to be keenly alive to all that the operator says and does, but has neither eyes nor ears for any one else. This is the so-called phenomenon of *rapport*. He is frequently partially and sometimes totally analgesic. Pin-pricks and pinches are felt as touches, and burns as warmth. Sometimes, although not as often, he presents hyperæsthesia of sundry senses. He can read fine type at a considerable distance, can hear sounds that he cannot hear in the normal state, or can distinguish the compass points when very near together. But the most marked and most constant symptom is his absolute obedience to the word and wish of the operator. If told that he cannot open his eyes, cannot bend his arm, he cannot. If told to open his eyes, he opens them; if told that an elephant, a ghost, or anything else you please is before him, he sees it; and similar hallucinations can be produced in all the other senses. Negative hallucinations can also be produced. The operator can by a word destroy sight, hearing, touch and other senses, or can make the patient blind to one object or person, deaf to one sound, or the voice of one person. Nor is it necessary that the suggestion be executed while the patient is in this abnormal condition. It may be executed hours, weeks, or even months afterward. Sometimes the patient passes spontaneously while executing it into the condition in which he was while it was given, and he is then usually not aware that he has done it. Sometimes he does not so relapse, but executes it in his normal state, and then he will often devise all manner of plausible pretexts for his action —anything, indeed, will he allege except the true reason, and that he rarely suspects. Finally, and this is a most characteristic symptom, no matter how deeply he appears to sleep, he can nearly always be awakened by a word. If I leave the patient undisturbed for a time while thus apparently asleep, all these phenomena usually disappear. He is no longer cataleptic, analgesic, hyperæsthetic, or suggestible; he is no longer *en rapport* with the operator, can no longer be awakened by the simple command; in other words, he is truly asleep in the ordinary sense of that word. Sometimes, however, if left to himself, he will awaken spontaneously, and no evil effects follow. He may feel a slight drowsiness, lassitude, or chilliness, such as we often feel when awakened from a nap, but nothing of a more serious nature need be feared.

I have described to you the hypnotic state in its most marked form—that which is known as deep sleep, or lethargy. About twenty per cent. of all normal and healthy adults, if we accept the conservative estimate of Dr. Doll, can be put into this condition. Of the other eighty-odd per cent., about twenty or twenty-five per cent. are not at all or but little affected by the agencies which I have described. A slight drowsiness and weight in the eyelids they will probaby feel, but no more. The remaining fifty-five or sixty per cent. are affected in various ways and to various degrees. Hardly will any two individuals present exactly the same phenomena, and scarcely any two writers agree upon the degrees that are to be recognized. Dessoir recognizes two, Charcot three, Forel three—but his three do not coincide with those of Charcot—Liebeault six, Chambard six, Bernheim nine, etc. Of these, the two proposed by Dessoir seem to me worthy of note. In the first grade only the power of originating voluntary movements is affected. Consciouness remains undisturbed, but the voluntary muscles are more or less withdrawn from voluntary control. The smaller and more high-

ly specialized groups, such as those controlling eyes, lips, tongue and fingers, are the first to be affected, then the larger groups. Suggestions affecting these muscles will then be executed, but hallucinations cannot be produced, nor will post-hypnotic suggestions be executed. In the second grade both the sensory and motor systems are affected and are subject to the suggestions of the operator. This is usually found in lethargy, but frequently without it. In the first grade only the functions connected with the efferent nerves are affected, in the second those connected with the afferent as well.

It is agreed by all observers that the most characteristic trait of hypnosis is the heightening of suggestibility. To this, catalepsy, automaton-like obedience, and the production of hallucinations can be reduced. Spontaneous analgesia and hyperæsthesia cannot be reduced to suggestibility unless the operator has carelessly dropped some remark in the presence of the patient indicating what he expects to find; yet in explaining suggestibility we shall, I think, find the clue to the explanation of these phenomena also.

Suggestibility is found in all normal individuals. Volumes have been written in illustration of the fact that the mere lodging of an idea in a man's mind is of itself a certain momentum tending to affect his action. It may take root and grow, or it may seem to have fallen upon barren soil and produce no effect. The world-wide phenomena of unconscious imitation, the influence which we unconsciously receive from our surroundings and exert upon one another, the curious epidemic manias of the Middle Ages, the periodic epidemics of crime, of which we have recently had several, all these are illustrations of the fact that the suggested idea is a momentum that has its own weight, which may indeed be overpowered, but which must always be taken into consideration. Now, in all degrees of hypnosis and in many conditions not classed as hypnotic the force of the individual idea is greatly exaggerated. In the most extreme cases it is no longer one of many momenta; it is the controlling power which seems to fatally determine what the man shall do, and even what he shall see and hear. Of such a man we say that his suggestibility has been heightened.

The explanation, therefore, of hypnosis, from the point of view of the psychologist, turns chiefly upon the explanation of suggestibility, and upon that we must for the present concentrate our attention. If suggestibility is characteristic of the normal man, its explanation must be found in the fundamental laws of mind and brain. We must then determine what conditions limit suggestibility in the normal state, and in what way we may remove these conditions and heighten it.

I must ask indulgence for a few minutes as I leave the problem of hypnotism proper and endeavor to sketch the main outlines of psychological theory or method which we find to-day very wide-spread among neurologists, and rapidly gaining ground among those pyschologists who bring to their proper work some acquaintance with physiology and pathology. According to this view all mental states are accompanied and conditioned by physical processes in the cerebral cortex. Upon this there is substantial agreement, and it may be regarded as the fundamental postulate of physiological psychology. Its converse, that every cortical process is accompanied by a mental state, is still disputed. If we admit this fundamental postulate, we are compelled to admit its corollary also,—that all the laws that govern mental states must admit of expression in physiological terms. And this corollary is fully borne out by the facts, as far as we are able to observe them. We must, then, learn to look upon the mental state precisely as we look upon all physical things. Scientific research in the physical world resolves itself into an inquiry into the causes and effects of phenomena, and the case is not otherwise in the mental world. The mental state must have its cause and its affects as certainly as the processes with which it is connected must have their causes and their effects. Its causes and effects need not form clearly distinguishable portions of the warp and woof of our conscious life. They may lie in the dim region that we call subconscious; but they exist, and if our knowledge were exact, we could reason to them deductively with infallible certainty. Now, when we examine our mental states narrowly, we find that even in all the complexity of consciousness we can frequently trace out their causes and effects. Let us examine a few of these cases.

Every mental state is susceptible of development. Its dimmest and least de-

veloped form is that of the nascent idea just emerging into consciousness. Its most developed form is found in the vivid sensation which is qualitatively like that idea. This intensity is primarily determined by the intensity of the central or centripetal stimulus by which the corresponding cortical process is awakened; but it also depends upon the cerebral constitution of the individual and upon sundry other conditions.

Mental states have effects. Their ideational effects have long been known to psychologists, and studied under the name of association of ideas. I need do no more than allude to this common phenomenon of subjective life. They have also motor effects. The relation of the vaso-motor system to the mental state is no new discovery. The blush of embarrassment, the pallor of fear, fainting at the sight of blood, are trite illustrations. Recent investigations have shown, however, that the connection between mental states and the distribution of the blood-supply is of the most thorough-going nature imaginable. Mental states also effect the voluntary muscles directly. To Alexander Bain belongs the honor, I believe, of having first established the relation of the motor idea to the production of the movement which it represents. The effect exerted by mental states upon the secretions of the skin, upon the salivary, mammary, and other glands, is a matter of daily observation; but their effect upon the processes of nutrition and repair is by means as common or as universally admitted. Yet it seems to me that we have sufficient experimental as well as clinical evidence to warrant our admitting the existence of such effects, although we do not as yet understand the nervous mechanism by which they are produced or the conditions under which they operate.

Not only have mental states positive, they have also negative effects. These negative effects are generally grouped under the the term "inhibition." They are exceedingly obscure. The development of any mental state seems to affect unfavorably the development of simultaneously nascent but independent states—a phenomena commonly treated by psychologists under the title "passive attention." Individual sensory states sometimes seem to arrest one another directly, perhaps by a species of interference. Motor states can certainly check one another. Into these and kindred questions I shall not at present enter. I have, I hope, said enough to illustrate the fundamental law of which I speak—that mental states, representing to us cortical processes of whose precise character we are wholly ignorant, must be regarded as belonging to the orderly system of nature quite as much as those cortical processes with which they are connected, and that we are entirely justified in ascribing to them those dynamic characteristics, those causes and effects which we ascribe to all physical phenomena. And into those characteristics, causes and effects it is the business of the psychologist to inquire.

It is evident that in an inquiry into the causes of any such state or process we must go over very much the same ground as we have gone over in dealing with its effects. It may be caused *ab intra* by the operation of such antecedent states and processes as I have just described, or it may be caused *ab extra* by some such perception. In general we term all states originated from without, "suggestions;" and those originated from within, "auto-suggestions." Of all the agencies by which I can originate an idea in the mind of another, none is as certain and as definite as language. Hence we commonly think of the suggested idea as having been suggested by words; but this is only accidental, not essential.

We have now completed our rapid survey of the dynamic mental state regarded as representing to us a cortical process. But it is evident that I have been presenting rather rare phenomena as illustrations of what I conceive to be one of the most fundamental laws of consciousness, and one may justly ask why this law, if it be ever operative, has so long escaped attention. The answer is not far to seek. If only our mental states existed singly, and each were free to develop itself and work out its own results without prejudice to or from other states, there would be little difficulty in determining what those results are. But in all normal states of consciousness the nascent mental state or cortical process finds itself in the midst of countless other subnascent, nascent, or definitely developed states, which it must modify, and by which it must suffer modification in countless and infinitely complex ways. It is, therefore,

very difficult in the normal state to isolate any state sufficiently to distinguish its results from those of others.

Moreover, there exists in consciousness an activity of which the would-be scientific psychologist, anxious to bring all mental phenomena under mechanical or dynamic laws, usually says as little as he may. And certainly at our present stage of knowledge it is impossible to analyze it into any component factors or to determine the laws of its operation. Yet we cannot well ignore it, since it is the most powerful single factor of conscious life. This is what we call the consciousness of self. Sometimes it appears to be latent, and the man reacts upon the stimuli presented to him with almost fatal certainty. But then, again, it appears, and forthwith introduces into the train of ideas and movements an element of capriciousness that was not there before. When it is thus present and exerts its influence over our actions we are said to act voluntarily. The character of this conscious self is largely determined by heriditary influences. But it is also genetically related to the permanent factor in past experience, and may even be described as a function of that permanent factor, since any extensive changes in the latter are sooner or later followed by changes in the consciousness of self. We are, I think, justified in believing that in this at present mysterious inner activity we see the present conscious representative of the net aggregate result of our own past experience, and to some extent that of our ancestors, confronted with and acting upon the nascent and mental state.

We are now in a position to form a more clear conception of what is meant by suggestibility and to point out the chief factors that normally limit it. When we say that suggestibility is characteristic of all men, we mean that any mental state tends to develop to a certain degree and to produce certain definite results. This tendency is not, as a rule, very noticeable, for two reasons: in the first place, any given mental state is but one of many, and we can rarely separate its results from those of others; and in the second, it is always exposed to modification by the most powerful and least understood element of consciousness—the self. I have also tried in passing to indicate those physiological conceptions to which this psychological theory is most nearly related, and, if there be any truth in them, it is evident that the condition which we find in the normal man implies an inconceivably complex inter-correlation and functional coördination between the several portions of the cortex and between the organized systems of processes which we must conceive as existing within it.

Under what conditions, then, does suggestibility become heightened? Heightened suggestibility is found occasionally as a spontaneous phenomenon. Pierre Janet has, for example, a patient who is as suggestible in the waking state as most persons are in hypnosis. She has never been hypnotized. It is sometimes found as one of the effects of certain drugs, among which are alcohol, ether, morphia, and chloroform. More light is much needed upon the question. Many dreams are due to the suggestions given by strong stimuli, which penetrate to the brain and arouse smouldering cortical processes, which pursue their devious ways unhampered by the restraints of waking life, hence the frequently grotesque and unreal character of dreams. It is sometimes possible to cause a person to pass from normal sleep into a condition of heightened suggestibility that cannot be distinguished from hypnosis. An analogous state frequently occurs spontaneously, and is known as somnambulism. But of all the means of heightening suggestibility with which we are acquainted, none is as easy of application and certain in its effects as the concentration of attention and limitation of the conscious field; and those effects are, so far as the subject can describe them, precisely what our study of normal conditions has led us to postulate as the chief requisite to the production of heightened suggestibility. Sometimes the entire field of consciousness appears to fade away. Then we may suppose that the only things in consciousness are the isolated ideas which the operator suggests. In others the definite heterogeneity of normal life gives place to a dreamy state in which the vivid self seems to have retired from the field. In others the self-consciousness remains, but finds itself so weakened that the commands of the operator appeal to it with irresistible power. This enfeeblement or destruction of the self is the most characteristic phenomenon of hypnosis, and is the chief

reason for the heightened suggestibility. The nascent mental state finds the chief obstacle to its independent development removed, and we can study that development and its effects under new conditions.

We must not, however, assume that the development and effects of the mental state in hypnosis are what they are in normal life, or what they would be in normal life were we able to remove other influences without in any way modifying the intrinsic character of the state which we wish to study. The checking or stilling of self-consciousness is the most characteristic change of hypnosis, but it is by no means the only change; and the other changes which are found in different subjects are so numerous that it is impossible to describe them. One of the most common symptoms is what may be described as a species of mental inertia. An idea which in the normal state would awaken a mass of associated ideas, and thus give birth to a long train of ideas, will fall dead and inert in the hypnotized mind; it seems to have spent its energy in getting to existence. But occasionally the exact contrary is observed. A mere hint from the operator lodging in the sensitive brain of the subject will be spontaneously developed into a tragedy or comedy, as the case may be, and be acted out with a vivacity and power of which the normal individual would be incapable. In these and other personal peculiarities, such as the spontaneous analgesia and hyperæsthesia which I have mentioned, we may recognize variations in the distribution of cerebral activity of whose exact character we cannot form even a conception, and which doubtless rest upon organic and dynamic peculiarities in the cerebral constitution of the individual.

What cortical modifications are we to conceive of as taking place in hypnosis? This is a question that is more easily asked than answered. I think we may say with some confidence that the normal cortical co-ordination of waking life is profoundly modified. This is indicated by the inhibition of the activity of the conscious self and the spontaneous alterations in sensation. But if we ask further just what portions of the cortex are chiefly concerned in this modification, it seems to me impossible even to propose a theory. We do not know whether the voluntary activity of the self is definitely related to some cortical area, as the various special senses are, or whether it is related to some cortical layer as supposed by some, or whether it is related to some organized system of processes distributed through the entire cortex. And as this is the physical activity which is most profoundly modified in hypnosis, we may suppose that those portions of the cortex which are concerned with its manifestation are those chiefly modified in hypnosis. Yet, as I have shown, we have reason to suppose that other changes take place whose exact character we do not know at all. If, however, we ask to what other changes this modification of the processes connected with the manifestation of self-consciousness are most nearly related, I think we may say with some confidence that they are most nearly related to the changes that normally take place in sleep. In normal sleep the continuous ebb and flow of molecular change that accompanies waking life slowly and regularly comes to a stop. Some little may remain in various portions of the brain, but it is for the most part, in a state of comparative quiescence. In hypnosis we have reason to think that a similar stilling of the molecular activities begins to spread throughout the brain. In some way which we cannot now explain, the fixation of attention and voluntary limitation of the conscious field inhibits the activities connected with the conscious self first. If we leave the patient to himself these activities will either reassert themselves, or else the same change will spread on throughout the brain until the patient is in a normal sleep. And in the case of some persons this is the only effect that we can produce by the use of the agencies which induce hypnosis in others. But if we do not leave the patient alone, but give him suggestions, we find that a large portion of the brain remains sensitive, that induced mental states or cortical processes —for some authorities contend that cortical processes in the hypnotized patient are not accompanied by any kind of consciousness—work out results which cannot be obtained in the patient while in the normal state. Hence hypnosis is in a sense a normal state artificially prolonged. It would, perhaps, be too much to say, with Mr. William James, of Harvard, that we all pass through the hypnotic state every night while going to sleep. It

seems to me probable that the methods which we use to produce hypnosis have a specific effect in determining the order in which the cortical activities are to sink into sleep, so to speak, which is not found in normal sleep. Yet the changes which take place in hypnosis probably do not essentially differ from those of normal sleep.

The phenomena of the hysterical condition, of epilepsy, of sundry forms of insanity, and of the rare trouble known as double consciousness, present many points of similarity with hypnosis, and we shall probably not be far wrong in classing all together as being due to derangement of cortical co-ordination. Sometimes, as, for example, in some forms of epilepsy, we have reason to believe that this disturbance is itself due to gross local lesions of the cortex. In many of these mental troubles we find derangement in self-consciousness and loss of voluntary control over different sensory or motor areas, and this is not seldom connected with heightened suggestibility. These facts have led many good authorities, notably Professor Charcot and the school of Paris, to regard hypnosis as a neurosis of the hysterical order depending upon some cerebral abnormality. I can, therefore, scarcely conclude this paper without making mention of this view and briefly indicating the reasons which lead me to dissent from it, although I do so with the modesty of the layman.

The researches of the school of Nancy have conclusively shown that the hypnotic state can be induced in the immense majority of normal adults, and they have been unable to discover any relation between susceptibility to hypnosis and hysteria, neurasthenia, or any other recognized disease. If, then, hypnosis is a disease, we are nearly all more or less tainted with it. This conclusion is supported by Moll, Dessoir, Wetterstrand, Forel, and many others. In the second place, I think that it is a nuisance of language to term a state which can be expermentally induced and ended, but which does not spontaneously occur, and which, when thus experimentally produced and ended, does not tend to unfit the patient for the duties of life, a disease. But if ever we find hypnosis occurring spontaneously, it would tend to interfere with the patient's discharging his duties as a member of society, and in that case we would be justified in regarding it as a true neurosis of the hysterical order.

I have said that hypnosis may be regarded as an artificial prolongation of an approximately normal state. But, one may ask, what is the effect upon the patient of this artificial prolongation of a normal state? If the hypnotic state involved, as I am inclined to suppose, a temporary dissociation of cortical processes normally co-ordinated, even though this dissociation be produced by normal agencies, may it not be that by fixing and prolonging it beyond the normal time we may loosen the bonds of union between the different areas of the cortex and produce a true hysterical neurosis? The question is most pertinent, and can be answered only by reference to observed facts. Some few cases of mental disturbance have been reported from the use of hypnosis, but such cases have been so few in number that we are justified in saying that the danger of such results in the case of the healthy patient in the hands of a trained operator is practically negligible. Some slight physical discomfort, as headache, drowsiness, and lassitude, are frequently found, but can usually be removed by suggestion. Headache is a very common symptom. But the only danger which is both serious and common appears to be the production of increased susceptibility to the hypnotic state. This is a very real danger, and we must ever be on the watch against it and cease experimenting at the first suggestion of it. Most authorities believe that we can always guard against it by the suggestion. We can to some degree, but know of no facts that show that the suggestion will last as long as the increased susceptibility to hypnosis.

Apart from the physical dangers springing from the use of hypnosis, we must consider the moral. That moral dangers exist there can be no question. Already several cases have been reported in which criminal assault has been committed by the aid of hypnosis, and the French experimenters have enticed patients to commit imaginary murders and thefts, to sign promissory notes, and to bear false witness in the same way. Yet I do not feel that our present knowledge justifies much apprehension on this score. We hear much in the literature of hypnotism of the cases in which the suggestions succeed, but little of those in which they fail.

And they very often fail, as I shall hope to show you. A suggestion whose execution the patient would find repugnant in the waking state will often meet with great resistance and sometimes fail of execution. The influence of the operator over his patient is much greater than in waking life, but it is perhaps never absolutely complete, and if there are persons who could be induced by hypnotic suggestion to commit crimes from which they would shrink while awake, such persons are probably exceedingly rare and their weakness is rarely suspected. One other danger remains which I must not fail to mention, and that is the danger springing from careless suggestions. I know a gentleman who thoughtlessly told his patient that the devil was after him, and had great ado to save the terrified patient from throwing himself from a sixth story window. The operator must ever remember that his every word is caught by the patient, no matter how impassive the latter may seem, and he must always be on his guard against saying anything of an exciting or terrifying character.

I have never seen any good reason for believing that there is any relation between hypnosis and telepathy. It is true that telepathic phenomena are from time to time reported as having been observed in hypnosis, but such phenomena are also reported in waking life. Most certainly the hypnotized patient is not, as a rule, sensitive to telepathic influences. But even if we admit that he sometimes is, it would not essentially modify the theory which I have outlined, and we would not be compelled to return to the theory of a force emanating from the operator and controlling the subject. We would merely be compelled to admit the possibility of a suggestion being conveyed in some way and by some means not at present understood.

In conclusion, let me say a word or two on the practical principles that should guide us in the use of hypnosis. No one should attempt it without having thoroughly studied the question, acquainted himself with the works of the great authorities, and having had some experience with an instructor. Its use should be limited to purposes of research, instruction, and therapeutics. A witness should always be present. The operator must rigidly respect the personal rights of the patient. He must have his full and intelligent consent to the experiment proposed, and must never endeavor to obtain influence over him at times or in ways other than those agreed upon. He must guard the patient effectually from any future inconvenience arising from increased susceptibility, and if he have reason to doubt his ability so to guard him, he must stop his experiments. And in the last place, and this principle includes all the others, he must ever have in mind and at heart the true welfare of his patient, and act in accordance with it.

DISLOCATION OF THE HEAD OF THE HUMERUS COMPLICATED WITH IMPACTED FRACTURE OF ITS ANATOMICAL NECK.

JOHN B. ROBERTS, M.D., PHILADELPHIA, PA.

A boy, nine years old, was brought to my clinic at the Women's Hospital on February 29, 1895, by Dr. Marie K. Formad on account of an injury to his left shoulder. About a week before Dr. Formad saw the boy professionally and ten days before I had an opportunity to examine him, he had fallen at school and struck his shoulder against a wall.

He had been brought to the hospital two days before I saw him, and Dr. Anna M. Fullerton, with Dr. Formad, examined him under ether and reduced what seemed to be subcoracoid dislocation of the head of the bone. Both of these physicians were struck by the flattened appearance of the deltoid region, and say that the bone distinctly snapped into place during the manipulations which they made. They could subsequently put the

boy's hand on his head and on the opposite shoulder. These positions could not be given the bone before etherization and reduction of the dislocation. The shoulder had still, however, an unusual appearance, notwithstanding the reposition of the luxated bone. The case was accordingly referred to me.

When I saw him the acromion was unduly prominent. The left humerus was apparently half an inch shorter than the right, and the width of the upper end was markedly increased. The greater tuberosity, which could be easily felt, for the boy was not very fat, rotated when the lower end of the humerus was grasped and given a rotary motion. The head of the bone, which I could feel in its normal position, also moved during this manipulation. I felt at times a grating like that of crepitus, but this did not seem to pertain to the humerus so much as to the scapula. It seemed to be in the posterior portion of the joint; but I could make out no fracture of the neck of the scapula, as was suggested by the situation of the grating.

The boy could voluntarily move his arm upward and outward without pain, though these movements were made in a guarded and careful manner, as though he feared suffering. The movements were not very extensive, but showed that the continuity of the humerus was maintained.

Being unable to make a diagnosis without giving pain I etherized him. I then found that rotation of the lower end of the humerus caused similar motion of the head bone, but that if I held the head still with my left hand I could, by means of my right hand holding the shaft of the humerus, cause a bending or rocking motion between the head and the shaft. This movement was between the greater tuberosity and the head. It was apparent that there existed a connection between the shaft and the tuberosity, and also between these portions of the bone and the head; but an antero-posterior rocking motion could be made between the shaft and the tuberosity on one hand and the head on the other. There was no fracture of the neck of the scapula and no dislocation of the head of the humerus.

Three conditions were suggested by these symptoms: First, a firmly impacted fracture at or near the anatomical neck, which allowed the whole bone to move when rotary motions were given to the shaft of the humerus, but which permitted bending between the head and greater tuberosity. Second, a partial or green-stick fracture at or near the anatomical neck. Third, an epiphyseal separation of the head with impaction. The fracture, whether impacted or of the green-stick variety, had permitted the dislocation, which also existed originally, to be reduced under ether by Dr. Fullerton and Dr. Formad. The rigidity maintained at the seat of fracture had been sufficient to permit the head of the bone to be put in place by leverage obtained from the shaft of the bone. The manipulations needed to reduce the luxation were not forcibly made, and the replacement was easily accomplished. Hence, the fracture could not have been produced by these efforts.

The widening of the upper end of the humerus, which was very conspicuous, and the apparent shortening of the humerus, inclines me to the theory of impacted fracture. The age of the child suggested, however, a green-stick fracture as a possibility. By forcible manipulation I obtained complete separation of the fragments. The sensation imparted to my hands was that caused by disentangling or breaking apart two pieces of bone. Subsequently the arm assumed the usual appearance of a fracture of the humerus close to the shoulder-joint. The crepitus originally felt in the vicinity of the scapula was probably due to the rough edges of the firmly impacted fracture rubbing against the border of the glenoid cavity. Having become convinced of the diagnosis, and having restored the proper conformation of the shoulder, I dressed the injury in the usual way—with a small pad in the axilla and a bandage to hold the arm to the thorax, which acted as an internal splint.

Union took place promptly. When I last saw the boy, about eight weeks after my first examination, there was a little unnatural prominence of the acromion, and the head of the humerus seemed to project forward a little more than usual. These appearances may have been due to atrophy of the deltoid. The movements of the joint were perfect.

We shall not need an epidemic of cholera when the new diphtheria antitoxine begins to get in its work.

THE MEDICAL AND SURGICAL REPORTER

ISSUED EVERY SATURDAY

Address all communications to P. O. Box 843, Philadelphia, Pa.

HAROLD H. KYNETT, A.M., M.D.
Editor.

RODERIC C. PENFIELD
Publisher.

Editorial Offices, 1026 Arch Street, Philadelphia, Pa.

Entered as second-class matter at Asbury Park, N. J.

TERMS:—Three Dollars a year in advance. Sent four months on trial for $1.00.

REMITTANCES should be made payable to the Publisher only, and should be made by Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We invite contributions of value to the profession, and if published originally in THE REPORTER such will be paid for at liberal rates, or a limited number of copies of THE REPORTER will be supplied, as the author may elect. Hereafter where reprints are desired writers are requested to make a note of that fact on the first page of the MS., but must order reprints directly from the publisher, who will supply the same at cost rates. Contributors should inclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, MAY 4, 1895.

EDITORIAL.

CONSENT IN SURGICAL OPERATIONS.

The surgeon is placed in a situation of great delicacy and embarrassment when the family of his patient, or some member of it, offers objection to the performance of an operation, the necessity for which is clearly indicated and recognized by the physician. Especially distressing is it when the patient is a wife and mother, on whose life and health depends the home, and, as is most common and most unfortunate, the objection is raised by the husband. If demanded to save life and the patient is conscious and sane and consents, the operation should be done no matter from what source the objections or who may be the objectors. The husband, by virtue of his position as head of the family, should have the privilege to choose the surgeon. It must not be concluded that he has no rights which are bound to be respected; that the solicitude natural to his relationship should not be honored. It is only where he is governed by selfish motives; where he values his wife but little more than he does his horse; where unreasoning prejudice or extraneous evil influence prompts his opposition, that he should be pushed aside and the welfare and will of the wife alone considered.

Few surgeons are willing to undertake a case where the husband or family prefer that the patient die, or pass into chronic invalidism and life-long suffering, rather than submit to an operation which would save life, increase the chances for ultimate recovery, or even alleviate suffering. For where he encounters such objections, the surgeon not only is subjected to increased anxiety in his surgical work, but he incurs the risk of possible annoyance, perhaps to the extent of pecuniary mulcting. There is too much needy and exacting work ready at hand, responsibility is too onerous, life is too short, to wait and worry and risk in cases where confidence is wanting, capability is unrecognized, where the work and its incident responsibilities are unappreciated, and difficulties and em-

barassments are thrown in the way of its successful execution.

Aside from the feelings of the family are other factors which operate to influence the patient: the talk of neighbors, lineal decendants of the comforters of Job; the gossip, who can give details of the operation and foretell the result—some one she knew told her all about a case somebody had heard some one else relate; the corner druggist, who kindly volunteers an opinion based upon his professional knowledge. Patients have been deceived as to real conditions by men anxious to operate or greedy for large fees. This fact often influences a patient and family, especially where the outward manifestations of disease are not indicative of its gravity. There is an almost irresistible tendancy to wait, in hope that "something will turn up" for the better. The profession in general, recognizes that, in many surgical cases, delay proves disastrous; that if it is not fatal, it results in chronic invalidism and places the patient beyond the possibility of complete recovery. In some cases more or less responsibility attaches to the attending physician who, ignorant of the real trouble or influenced by some questionable motive, discourages operation and even examination by some specialist in the suspected condition.

On the other hand, the surgeon must feel confident of his position. There are errors committed so willfully, selfishly and wantonly, that even that charity which "covereth a multitude of sins" can not palliate them. Surgery, and particularly gynecological surgery, is full of temptations seductive to one ambitious for name and gain; temptations which appeal to many very weak points in human nature. The true surgeon will obliterate thoughts of self and consider the issues of his work. These are momentous, for they deal with human life, with time and with eternity. No man can envy success gained in the way indicated by the dying declaration of a distinguished specialist, operator, writer and teacher, that more than one-half of his operations *were done for money*. The lesson in this confession should sink deep in the surgical mind, and yet deeper into the surgical conscience. When there is less of needless meddlesome operative interference, less of ignorant blundering work done, there will be less of objection raised where conditions indicate the necessity of resorting to surgery.

Legally considered, to justify a surgical operation upon a married woman, her consent and not that of her husband is necessary. A married woman cannot be compelled to submit to an operation; but if she voluntarily submit to its performance her consent will be presumed, unless she was the victim of fraudulent misrepresentation. Even if the disease resulting in death was caused by the operation, the surgeon is not liable if he performed the operation with the patient's consent, in a careful and skillful manner, and under the belief that it was proper to be performed.

The party who allows a surgical operation to be performed is presumed to have employed the surgeon for that particular purpose, and it will be presumed that the operation was carefully and skillfully performed in the absence of proof to the contrary.

A judge of the Supreme Court of Maryland, rendering a decision in a case in point, tersely and aptly states the principle governing in the matter of consent:

"Surely the law does not authorize the husband to say to his wife, 'you shall die of the cancer; you cannot be cured, and a surgical operation, affording only temporary relief, will result in useless expense. The husband has no power to withhold from his wife the medical assistance which her case might require. The consent of the wife, not that of the husband was necessary."

It was said by the Supreme Court of Michigan, in a recent case:

"It would be a cruel rule for her, the wife, if she cannot, in the absence of the husband at least, or in his presence if he does not himself provide for her, make a binding agreement for any necessaries, whether articles to be provided, or professional help. It is not to be expected that physicians and surgeons will always feel bound to render gratuitous treatment to injured persons, and when the occasion s pressing, it would be unreasonable to delay until an absent husband is communicated with to learn whether he consents or refuses to assume her contracts. Time will not allow minute inquiries, humanity will not prompt them. It seems to us that no sensible line can be drawn between contracts for food and clothing and contracts for medical aid."

ABSTRACTS.

THE MANUFACTURE OF DIPHTHERIA ANTITOXINE.*

The discovery of antitoxine as a new agent for the prevention and cure of diphtheria was announced by Prof. Emil Behring, of Halle, about four years ago. Although received at first with more or less incredulity, the new remedy has borne successfully the test of actual use by a number of eminent practitioners in Germany and other countries, several of whom presented reports embodying their experiences and conclusions at the recent international medical conference, in Buda-Pesth, antitoxine now is recognized by all the authorities as one of the most useful and interesting discoveries in modern pathology.

Since the publication of Dr. Behring's treatise on the subject, no secret or mystery has surrounded the nature of antitoxine or the conditions of its use so far as these had then been demonstrated, but, for the reason that its manufacture is difficult and expensive, involving tedious preparation of materials, scrupulous care, and the use of complicated apparatus of production, the new remedy has until quite recently fallen far short of meeting the constantly growing demand, which, especially since the conference at Buda-Pesth, has come with increased insistence from every civilized country where diphtheria is recognized as one of the most fatal and persistent scourges of the human race.

Through the employment of a liberal endowment, raised by popular subscription at Paris, antitoxine has been made there for the supply of the local hospitals, and measurably for the use of practicing physicians throughout the city and immediate vicinity. A small quantity has been produced at Berlin, and establishments for its manufacture are in construction at Milan and Buda-Pesth, but the place where it has been and now is manufactured in quantities at all commensurate with the demand is at Hœchst-on-Main, near Frankfort, Germany.

The material at first used was the blood of sheep and goats, but, for the reason that those animals in grazing were liable to eat plants which might affect the quality of their tissues, recourse was had to horses, which now are employed exclusively to furnish the blood-serum in which the antitoxine is developed and contained.

A description of this interesting manufacture involves necessarily some account of the nature of antitoxine and the principle upon which its prophylactic action depends. Dr. Behring found that when an animal by nature susceptible to diphtheria was inoculated repeatedly with gradually increased doses of diphtheria poison it became finally immune to the poison of that disease, and there was developed in the tissues of the animal so tried an antitoxine principle which had the power to neutralize and render innocuous the poison which was secreted by the

*From the official report of Consul-General Mason, at Frankfort, Germany, to the U. S. Government.

diphtheria bacillus, as demonstrated in 1884 by Lœffler—the poisonous secretion, as is well-known, forming the source of danger in diphtheria.

The neutralizing agent thus created is named antitoxine, and is the specific which forms the basis of the new treatment of diphtheric diseases, both as a preventive and as a remedy in cases that actually have been developed. Precisely what this antitoxic agent is has not been demonstrated. Chemistry has not separated and defined its constituent elements, but its action is perfectly understood as analogous to that of hydrated oxide of iron when used as an antidote for arsenical poisoning. In the presence of arsenic the oxide unites with the poison and forms a combination which is not poisonous. In a smaller manner the antitoxine attacks and neutralizes the poison secreted by the bacillus of diphtheria, and this, so far as experience has shown, without subsequent injury to the tissues or prejudice to any of the functions of human life.

Antitoxine may be obtained in a highly concentrated form by either of two methods: First—Through precipitation from the serum solution by means of sulphate of ammonia or hydroxide of aluminium, and in this case the resulting precipitates are mixed with alkaline solutions and evaporated in vacuo at low temperature. Second—The original solution may be evaporated directly to dryness, leaving the dessicated antitoxine as a residue.

The essential conditions in the preparation of diphtheria antitoxine are absolutely pure and healthy animal serum, thorough knowledge of bacteriological processes, absolute cleanliness and care at every stage of the operation. The horse is one of the most susceptible of animals to diphtheria, and, being not only tractable and easily kept under requisite conditions, but capable of supplying a large quantity of blood, is best suited for the purpose. The horses now in service at Hœchst were chosen with every precaution—the requisites being youth, vigor and perfect physical health.

No racing thoroughbred was ever housed, fed, watered, exercised and cared for more scrupulously than these chosen animals which give their blood for the healing of human kind. The stables are under the supervision of a veterinary surgeon, and when a new horse is introduced he is kept for a period under close observation to detect any symptom, however slight, of antecedent injury or disease. If no such defect is discovered, he is put on the active list, his stall is numbered, and a special book is open for him, in which every detail of his daily treatment and condition is carefully recorded.

He first is inoculated high up on the shoulder with a small or weakened dose of diphtheria poison of living bacilli. Thus far his temperature is frequently taken, and his appetite, his general aspect, the condition of the wound made by the hypodermic syringe, etc., are minutely observed and recorded. After the proper interval the inoculation is repeated in gradually increased doses, until the horses become immune to the poison of diphtheria. Every tissue of the animal's body now contains antitoxine, but the blood is the substance which most readily can be withdrawn without injury to life and health, and the blood alone is used.

It is important to ascertain definitely when the treatment of each animal has been continued sufficiently to render it immune and fully developed of antitoxine in its tissues. This is done by drawing a small quantity of its blood, separating the serum, and mixing this with a specified quantity of the diphtheria poison, such as otherwise is used for inoculation. With this mixture a test animal—usually a rabbit or a guinea pig—is inoculated, and the result is observed. If the test animal becomes ill from diphtheria, it is proved that the antitoxine in the horse's blood was not sufficiently developed to neutralize the requisite volume of poison, and the inoculatory treatment is therefore resumed. But if the test animal shows no ill effects the potency of the serum is thereby established and the horse is ready to become a producer of antitoxine.

The amount of blood that a strong, healthy horse can supply without apparent injury to its physical condition is somewhat surprising. Record books at Hœchst show that from one of the horses 10 liters (21.13 pints) of blood have been drawn within two days; another has yielded 21 liters in eight days, and the average for each animal varies from 25 to 50 liters a month. All have at present the appearance of good health, and some have even grown fat under the ordeal. Dr. Behring, who has drawn blood from the same horse

for nearly four years, states that it is in good physical condition.

The blood thus obtained passes to the laboratory, where the serum is eliminated, exposed to a degree of heat which destroys the last vestige of any form of bacillus that it may contain, and then is prepared for use by processes, a description of which would extend unduly under this report. As a final precaution against the survival of any bacillus, and to avert danger of decomposition from bacterial growth, 5 per cent. of carbolic acid is added to the antitoxine serum, and in this condition it may be kept in a cool place, with exclusion of light, for months without the loss of much antitoxic power.

Horses vary individually in respect to the strength of the antitoxic serum they produce, and the finished product is prepared in three degrees of strength, numbered respectively, 1, 2 and 3, which are indicated by different colored labels on the vials in which it is sold for use. In the use of antitoxine, either as a prophylactic or remedy, the strength of the serum employed is a point of importance to the physician, who should know precisely the antitoxic energy of the dose administered. It was, therefore, necessary to formulate a system of measurement for this energy based upon a definite and invariable unit. This has been done mainly through the labors of Drs. Behring and Ehrlich as follows:

The bacilli of diphtheria are propagated in bouillon. The amount of such poison that a given measure of bouillon will contain is fixed and definite like the limit of saturation in many saline and other solutions. The deadliness of this maximum solution of diphtheria poison may be inferred from the fact that one-fourth of a cubic centimeter of it administered hypodermically will kill a guinea pig of 250 grammes weight. The relative strength of this normal bouillon toxine and the antitoxine is as ten to one—that is to say, one measure of antitoxine will neutralize ten measures of *Normangift*, which is the German name for diphtheria bouillon. The standard strength and the energy contained in one cubic centimeter (one-thirtieth of a fluid ounce) of such antitoxine forms the unit of measurement of antitoxic power.

But some horses yield far more powerful serum than others, and the serum may be produced so powerful that one-tenth of a cubic centimeter of it will neutralize ten centimeters of poison. One cubic centimeter of such serum would thus contain ten units of antitoxic power, and would be designated as "tenfold serum." The strongest serum yet produced is "140 full," one measure of which neutralizes 1,400 measures of the normal toxine solution.

The finished antitoxine is a clear, amber-colored fluid, soluble in water, and is put up for use in strong, carefully closed, sealed and labeled vials, having a uniform capacity of ten cubic centimeters, or one-third of a fluid ounce. The exact bulk of serum in each vial is regulated according to its number and strength, as follows:

Antitoxine No. 1 (green label) contains 600 units of antitoxic energy, and is used in mild cases and for young children, or as a preventive to inoculated children or adults who have been exposed to diphtheria, but are not yet attacked visibly. The prophylactic power of antitoxine is estimated at ten times its curative virtue, so that a subcutaneous injection of one cubic centimeter of serum No. 1 is generally regarded as sufficient to avert diphtheria.

Antitoxine No. 2 (white label) contains 1,000 antitoxic units, and is used for older patients and where treatment has not been commenced until the attack is fully developed.

Antitoxine No. 3 (red label) contains 1,500 units of strength, and is employed for severe cases where malignant symptoms prevail and treatment has not begun until the disease has reached a critical stage.

It is more than probable that with further experience the importance of the highest of these three grades of serum will be diminished greatly, and instead of one injection of highly-concentrated antitoxine, repeated doses of the weaker quality will be preferred. The principle has been fully established that the requisite number of antitoxic units can be supplied, even in severe cases, by simply repeating the injection of serum No. 1—in other words, it is quantity, not quality of strength, that is required, and Prof. Behring is of the opinion that ultimately only one serum of standard and uniform strength will be used.

It also has been found that age has as

important salutary effect upon antitoxine. In the earlier experiments, when the supply of antitoxine was small and temporary, freshly-prepared serum was mainly used, and produced in some cases a slight eruption of the skin. This was the outward sign of a disturbance, the ultimate consequences of which caused some fear, but later experience has shown that this eruption is not caused when serum which is ripened a few weeks is used. Instead of degenerating, antitoxine improves with age, at least during the first two months, and the best German practitioners no longer use freshly-prepared antitoxine when that which has undergone the ripening process can be obtained.

All authorities agree that an early application of the remedy is of the utmost importance. At the Lazarus Hospital, in Berlin, where 72 cases of diphtheria in children were treated within 2 days of first appearance, only 2 cases were fatal, and Dr. Kossel estimates that in such favorable conditions the death rate can be reduced to 4 per cent. It follows from the nature of antitoxine that it can have no curative effect in cases of any disease other than diphtheria such as are caused by the Loeffler bacillus, and no exact and conclusive statistics can be prepared until such cases are carefully distinguished from scarlatina and the other kindred diseases in which the real diphtheric bacillus is not present.

Only the careful experience of years by a large number of physicians can settle definitely all the questions that have been raised by the introduction of antitoxine; so its precise value as a preventive or remedy, in determining finally whether its use when properly prepared and administered entails any danger or injurious effects upon the patients, although inconclusive from a scientific standpoint, is certainly most important.

SOME PRACTICAL POINTS IN OBSTETRICS.

Crow, in the *Virginia Medical Monthly* gives the reasons which have led him to adopt the following routine as regards antiseptics in obstetrics. While it was not the result of scientific bacteriological investigation, but purely that of practical results obtained in the treatment of about eight hundred cases, it is nevertheless, in accord with the results of our scientific investigators, namely:

1. If the patient tells him that she has no abnormal secretions from the vagina, then he advises a plain douche of hot soft water at the beginning of labor.

2. If she has an adnormal secretion, then he advises a douche of hot water, carbolized, once or twice a day prior to expected confinement.

3. If the secretions are profuse and irritating to the parts, then he advises a local treatment as a means of relief, in connection with the carbolized douche.

4. A five per cent. creolin solution he finds the best antiseptic lubricant for the hands of the accourcheur at the time of confinement.

5. He uses a dressing of boric acid on absorbent cotton over the vulva, changing it whenever the cotton becomes saturated, and then bathes the external parts with some warm antiseptic solution.

6. He neves advises a vaginal douche for the first week or ten days after labor in normal cases with no rise of temperature.

7. He tries to impress upon the nurse the importance of thoroughly cleansing her hands before attending the patient.

Even with this treatment arrest of flow, rise of temperature, etc., sometimes occur, probably due to undue exposure of the patient and using water of too low a temperature in bathing, and lack of proper cleanliness on the part of the nurse, especially in families where the nurse in attendance has to be cook, washerwoman, housekeeper, and attend, perhaps, to the numerous wants of older children, etc.

It should be remembered that nature does a great deal in throwing off the material for sepsis to take hold of; and too much interference with the mother in the way of douches and washes repeated too often during the first few days is harmful, for it breaks her rest and adds to the already high tension of the nervous system, which is altogether unfavorable to the normal restoration of the functions.

THE DISINFECTING POWER OF SOLAR RAYS.

Certain articles, as furs, leather, etc., cannot be disinfected by steam, since they are thereby rendered useless. Others, which are certainly amendable to such treatment, as fixed upholstered articles of of furniture, cannot be removed for the purpose. To disinfect these we have recourse to gaseous agents, and they, according to the results of experiment, are not always reliable. An exception possibly lies in formalin, which has recently been recommended by Lohman (Munchener *Medical Wochenschrift*). Another means of disinfecting such articles consists in the use of solutions of carbolic acid or corrosive sublimate. In the case of wooden and metallic articles, with smooth hard surfaces we can rely on the result, if they are first thoroughly sprayed with the liquids and subsequently washed, but such is not the case with thick woolen materials. Duclaux, (*Review Scientifique,*) found that some bacteria are destroyed by sunlight, and he refers to this as an important agent in the sterilization of the atmosphere. Arloing (*Compt. Rend.*,) proved that anthrax bacilli are destroyed by the solar rays. Koch has also shown that tubercle bacilli cannot be exposed to the same for very long and survive. Fermi and Celli (*Centralblatt f. Bacteriologie*) in a series of experiments, demonstrated that germs in aqueous suspension are likewise killed, and Baspe (*Dissertation Schwerin*) asserts that the sun is able to hinder the development and even destroy bacilli lying on the surface of the soil or submerged in water. But no experiments have been hitherto made to determine how far these rays may be used as disinfectant of clothes, bed linen and furniture.

It is common custom to expose the clothes, bed linen and mattresses to the air and sun, especially after death, possibly in the hope that currents of air may diffuse evil odors more quickly. Nevertheless, it seemed of importance to the author to investigate how far such results were trustworthy, and how far they were attributable to the direct effects of the solar rays.

Esmarch used pillows, varying the contents, skin, etc., and bacteria, as pure cultures, or pus containing micrococci. He imitated the natural conditions as far as possible. The materials were contaminated with the solutions placed in the sun, either at once or after drying. Control experiments were made. He arranged wool, cloth, etc., in layers, and in the first series of experiments to prevent the falling of atmospheric microbes during the exposure, he placed the pieces in a box covered with a glass pane, and provided at the sides with openings for ventilation. The temperature of the interior, however, rose much higher than that of the air (30°) and vitiated the results. In subsequent experiments the objects were always placed on the grass in the sun. Esmarch concludes that the sun's rays have a marked action on the surface, but that this speedily becomes lost when bacteria are protected by layers of material. The cholera bacilli, even in the deepest layers, were killed; but this is not surprising since dessication, lasting but a short time, is fatal to it. An exposure, lasting eight to ten hours, yielded but unsatisfactory results. After one day she diphtheria bacillus was killed in the interior of the pillows, but when protected by the woolly hair of a sheep's skin, 39 hours were insufficient. Streptococci within the pillows, and the skins withstood a five days' exposure. Esmarch then sprayed infected articles with two per cent. and five per cent. solutions of carbolic, and found that the weaker acid is little better than the sun, and that five per cent. is not altogether reliable. (Ueber sonnen desinfection. E. Von Esmarch, *Zeitschrift f. Hygiene.*)

The Value of Diphtheria Antitoxin.

The discussion on the value of the diphtheria antitoxin at the Berlin Medical Society, was concluded at the third session of the society. *Med. Rec.* Dr. Schiemmann warned general practitioners against employing the antitoxine, which he said should be left to hospitals for the present. Professor O. Liebreich, director of the Pharmacological Institute of the University, criticised the published serum statistics. He said that the Berlin hospitals had always had a much higher percentage of deaths from diphtheria than the Berlin town practice. This was because, broadly speaking, only serious cases were brought to the hospitals.

THE TREATMENT OF TETANUS BY ANTITOXIN.

A successful case of tetanus treated by antitoxin is reported by John Marriott, M.B., in the *British Medical Journal* for January 19th. The symptoms began six days after the injury—a wound in the jaw caused by a missile from a catapult—with inability to open the mouth and difficulty in swallowing.

On the ninth day, when the patient was first seen by Marriott, the muscles of the neck and back were stiff and prominent, and there was well-marked trismus. Disinfection of the primary focus, administration of chloral, as much as could be swallowed, and physostigmine (one-one-hundredth grain) hypodermically during the next two days did not relieve the symptoms, which became gradually more aggravated, until on the fifth and sixth days there was slight opisthotonos. Two and one-half grammes of Tizzoni's antitoxin were now given hypodermically, the necessary punctures causing strong opisthotonic spasms. On the next day, the thirteenth of the disease, the patient was able to swallow a little. One gramme of antitoxin was given. The following day swallowing was easier. Speech was unintelligible, but the patient could make himself understood by writing in large jerky scrawls; one-half gramme of antitoxin was given. During the following days gradual improvement was noted, one-half to one gramme of antitoxin being given daily until the twenty-first of the disease, when none was administered. The jaws at this time were still clenched. On the twenty-second day of the disease, early in the morning during sound sleep, the jaws opened sufficiently to allow the tongue to protrude and when the patient woke the tongue was caught and firmly held. The irritation caused renewed spasms, embarrassment of respiration, cyanosis. Attempts to administer chloroform only made matters worse. Although the patient appeared to be dying, one-half grain of morphia with one-fiftieth of physostigmine was given with success in causing relaxation of the spasm and release of the tongue. Recovery from the morphia was followed by a return of the spasms, which were successfully combatted by antitoxin. The case progressed to recovery, and the patient was able to sit up on the thirty-fourth day.

The second case, which terminated fatally, was one of tetanus neonatorum, treated by antitoxin. The child had been delivered by a midwife, and the disease appeared on the eighth day of life. On the fourth day of the disease it was first seen by Dr. T. Lacy Firth, who reports the case.

On the fifth day of the disease there was jaundice, the eyes were tighly closed so that the lids could not be opened. The jaws were set and the neck and spine rigid. The child could be held in a vertical position by holding the legs only. A part only of the milk introduced into the mouth was swallowed, and the attempt produced cyanosis and short feeble cries. Nutrient enemata, chloral and bromide constituted the treatment.

On the seventh day an alarming collapse took place, but passed off. Similar attacks followed on succeeding days. On the tenth day there were eight of these attacks and the child died in the evening of this day.

On the eighth day of the disease four-tenths of a gramme of antitoxin was given subcutaneously, and during the ninth day two injections of the same amount were given.

On the tenth day eight-tenths of a gramme was given at one dose. The total given thus was two grammes.

In the *Quarterly Medical Journal* two cases of traumatic tetanus in adults are reported, both successfully treated by antitoxin. The antitoxin treatment was begun on the ninth and third days of the disease, respectively. In both these cases repeated doses of the antitoxin were required, and improvement in the symptoms followed each dose.

It is interesting to note that in the last case, a child of six, a rash resembling measles with fever and swelling of the cervical lymphatic glands appeared on the twelfth day after the discontinuance of the antitoxin.

That a similar rash has been often noticed after the antitoxin treatment of diphtheria is interesting, and points to the fact that the rash may be due to the serum

itself and not to the particular antitoxin it contains. The failure of the serum in the case of tetanus neonatorum cannot be considered as indicating its unreliability, when we consider that the eighth day of the disease in a new-born child is a much later period with reference to effective treatment than it is in an adult. The possibility of complications, as suggested by the jaundice and attacks of collapse, which are not usually symptoms of tetanus, is present. Unfortunately no autopsy was allowed.

In the light of these cases, and in view of the widespread reports of the success of antitoxin in diphtheria, we think the time has come when public authorities should take into serious consideration the general problem of assuring to the profession and to the public reliable sources of supply of such antitoxins as are proved by sufficient and careful experience to be curative.

FREE BLOODLETTING IN PUERPEPAL ECLAMPSIA.

D. Dwyer, M.D., writes to *New York Medical Journal:* On Friday, November 2, about 9 P.M., I was called to see Mrs. J. M., who was, as she supposed, about to be confined. On my arrival at the house I found her in bed, apparently quite comfortable. The first thing which I did, of course, was to make an examination. From this I concluded that the labor had not at all begun, and by the way, previous to my arrival, she had had no pains other than some stomach irritation. I could find no dilatation of the os, and was about to leave and return to my office after having remained about an hour, when she suddenly complained of dimness of vision and in a very few moments complete blindness. I anticipated the future, as we all, as practitioners of medicine, know what this means.

It was only a very few moments until she went into a convulsion which, indeed, was very severe. I could do nothing, only keep the teeth apart at the next. However, I had my chloroform ready and administered it in the usual way, and I am sorry to say with little effect. I remained at her bedside till 5 the next morning, when I left and returned to my office te see if I could find anything in my library that would enlighten me on the subject, and there, as Professor Ford, of the University of Michigan, used to say, "I succeeded in failing."

It was utterly impossible to get my medicine into the stomach, for she was unconscious from the first convulsion until we resorted to bloodletting. The convulsions came on every fifteen to twenty minutes. On the next morning, about 8 o'clock, I called Dr. Blackslee in consultation, and on making an examination we found the os considerably dilated.

What, then, were we to do? We tried injections, but they were of no avail. We then, as the heading of my article indicates, resorted to free bloodletting. We opened the median basilic vein and drew therefrom a quart and half a pint of blood. We had no sooner done this than the patient regained consciousness and was immediately delivered of the child, which in our opinion, was at about the seventh and a half or eighth month; it lived four to five hours. The woman got along very well with medication. As soon as she would take any, we gave diuretics and cathartics.

This I consider a rare case on account of the extreme amount of albumin in the urine.

Seborrhoic Eczema in Children.

Feulard, (*Brit. Medi. Jour.*,) observes that attention must be given in the first place to the diet, which should be limited to milk, with the addition, in older children, of eggs. In the local treatment the first step is the removal of crusts, which may be effected by using warm coal tar lotions, preceded, if necessary, by poultices. After the crusts have been removed he uses gauze compresses soaked in a solution of resorcin (6 in 1000). These are kept constantly applied to the scalp by day, and are applied frequently to the face. By night an ointment is used, consisting of one part of balsam of Peru to thirty parts of vaseline. Later he uses fine starch powder, or a powder consisting of equal parts of starch and carbonate of bismuth.

PERISCOPE.

IN CHARGE OF WM. E. PARKE, A.M., M.D.

MEDICINE.

Hydrosulphate of Calcium and Protosulphide of Barium as Depilatory Medicaments.

The depilatory action of the hydrosulphate of calcium and of the protosulphide of barium has been studied by Annequin (*Archives de Med. et de Pharm. Militaires*). The sulphydrate of calcium is an unstable body, losing its sulphydric acid under the action of carbon dioxide, and in the presence of air it is slowly oxidized. The odor of sulphydric acid may be masked by a combination with some aromatic essence, such as peppermint, bergamot, etc., in the strength of one to two per cent. Calcium sulphydate, locally applied in the form of a paste made with water, has caused the softening and detachment of a finger-nail in about an hour, and in two hours that of a toe-nail. A longer time is required to produce a similar effect on horny growths or corns. A growth about five millimetres (one fifth of an inch) thick has been destroyed in about twelve hours. The action of the medicament is enhanced if the growth or corn to be treated be previously subjected to a sort of maceration. Many other alkaline sulphydrates and sulphides associated with a caustic base have a destructive action similar to that of the sulphydrate of calcium, but they affect the roots of the hair and prevent the growth of this; hence the superiority of the calcium base. This does not injure the dermis nor the hair-roots, and its action is rapid and painless. Next to this body, the best depilatory agent is said by the author to be the protosulphide of barium. The application of this substance is also very simple. A layer of the paste is applied to the part to be treated, and in about from six to seven minutes all the hairs are destroyed. The barium protosulphide is superior to the calcium base, in that it is odorless, more rapid in its action and cheaper. It causes a slight smarting, which only lasts a short time. This latter effect may be diminished by associating the medicament with oxide of zinc, but under these circumstances the rapidity of action is lessened. The protosulphide is the only sulphide of barium, so it is asserted, that exercises a depilatory action.

Raynaud's Disease With Complications.

The following account of a case of this rare condition is given by T. K. Monro (*Glasgow Medical Journal*): The patient, a girl, when first seen was twenty months old. She had marked hydrocephalus. There was a striking discoloration of the skin, which was said to have been present at birth, and at one time had existed over the whole body. Cold and crying rendered the discoloration more conspicuous, while heat rendered it less so. At present there are blue mottled patches on the face, legs and arms, and the back. There was extreme lividity or actual gangrene of portions of the extremities, especially of the second left toe and of the second right toe. Apparently there was little or no pain.

The patient was again seen five and a half months later, and two months after that, there being at both times a slight improvement. Three weeks later she was decidedly worse, owing probably to the cold weather; and a slight swelling immediately above the sterum was noticed on crying, which proved to be a diverticulum of the trachea, and a vertical slit in the wall of the trachea could be felt. She now suffers considerable pain, and is constantly crying. A dark-blue, almost black, spot is commonly present on each cheek. The reddish color is well marked on the hands and wrists, the back and the hip. The second toe of the left foot is decidedly worse, and viewed from above the distal half is of pure blue (not black and not purple) color. The plantar surface is almost entirely blue. There is no blackness on the right foot, and there has never been any on the fingers. Nothing abnormal has been detected with regard to the heart, and the urine contains no albumin, no blood and no sugar. There is no clubbing of the fingers, no muscular palsy or wasting, and no loss of sensation or swelling of the joints. There is no fever, no uticaria and no scleroderma.

The Use of Antipyrin in Large Doses.

One case of hysterical fits and two cases of chorea are reported by McCall Anderson (*British Medical Journal*) to show the good effects of antipyrin administered in large doses. According to the writer, antipyrin is the most valuable of all the coal-tar derivatives. The initial dose should not exceed ten or at most fifteen grains. When this quantity is well borne it should be increased cautiously to forty and even fifty grains three times a day. The author concludes that:

1. Antipyrin is not the dangerous drug which some observers have led us to suppose.
2. It may be given in safety in large doses, even in the case of children, in most cases, although the initial dose must be small, and it must be slowly and cautiously increased, the patient being always carefully supervised.
3. In large doses it often yields surprisingly good results, and in chorea it is the only medicine from which cures may confidently be anticipated.

Breakfast for Chlorotic Girls.

Dr. Carl Van Noorden, in the *International Medical Magazine*, speaking of the dietetic

treatment of chlorosis, says: "Most chlorotic girls feel the weakest and worn out most during the hours of the forenoon and incapable of any proper kind of work. This condition is uncomfortable and directly harmful, from the educational point of view. The best remedy is the English fashion of a good hearty meal at the beginning of the day. Chlorotic girls are advised to drink half a litre of milk of the best quality while still in bed, and do it very slowly, taking fifteen minutes to drink the quantity prescribed. Half an hour later they should rise and be rubbed with a dry, rough woolen towel. Then comes the breakfast, consisting of a small cup of tea, one or two slices of buttered toast and plenty of meat. Two hours and a half later some bread and butter is to be eaten, together with two eggs, this to be followed by a quarter of a litre of milk. A glass of sherry is now permissible if special reasons warrant it. This morning regulation or diet makes the forenoon hours quite comfortable. Fixed rules for other meals are of less importance."

The Care of the Ear During the Course of the Exanthematar

Dowine (*Journal of Laryngology, Rhinology and Otology*), says that two-fifths of all middle-ear cases examined by him originated during the course of measles and scarlet fever; but this does not indicate the number of cases in which the ear is affected during these diseases, but rather points to the proportion of chronic ear affections which follow them. Many acute cases prove fatal; while others, on account of their acute character, have active treatment applied early, by which structural changes are prevented For relief of nasal discharges the patient should be directed, from the very beginning of illness, to use the handkerchief freely; and if the child is too young to do this, Politzer inflation should be resorted to. Where the case does not come under observation till a late stage, and the pain in the ear is acute, and relief is not obtained by inflation, the membrane should be examined and incised without delay, especially if there be a sudden rise in temperature without any other explanation. This operation is of incalculable benefit to the patient, for it not only relieves the immediate pain, but saves the deeper structures of the ear and prevents the misery of a chronic otorrhœa, with its numerous attendant risks.

Hypodermic Injections of Pilocarpine in Meniere's Disease.

These cases were treated by Labit, in Moure's clinic at Bordeaux (*Rev. de Laryngol., d'Otol., et de Rhin.*), and occurred in a governess aged sixty-eight, a stoker aged forty-nine, and a female cook aged twenty-eight. The first had previously been affected with sclerotic catarrh of both middle ears; the others were quite free from any aural disease of the kind, but were, from the nature of their occupations, exposed to extreme heat. In all there were the typical symptoms—noises, vertigo, nausea or vomiting, and deafness to osseal as well as to aerial sound vibrations. In the second case one ear only was affected. The first received fifteen injections of from $\frac{1}{4}$ to 1 centigramme (about $\frac{1}{75}$ to $\frac{1}{15}$ grain), the second thirteen of from $\frac{1}{2}$ to 2 centigrammes (about $\frac{1}{15}$ to $\frac{1}{3}$ grain), and the third eight of from $\frac{1}{4}$ to $1\frac{1}{2}$ centigrammes (about $\frac{1}{75}$ to $\frac{1}{4}$ grain), continued and increased. In all the cases the vertigo disappeared, the noises diminished, and the hearing was to a certain extent restored. The writer compares the absorption produced to that observed in pleural and peritoneal effusions under the action of pilocarpine. Success depends upon the correctness of the diagnosis and the early adoption of the treatment.—*Brit. Med. Jour.*

Clinical Value of Renal Casts.

Many clinicians can recognize casts under the microscope but fail to interpret their significance. Dr. A. E. Austin, in the *International Med. Magazine*, separates them into definite groups and draws inferences accordingly. The hyaline and blood casts merely indicate irritation and hyperemia. Closely associated with hyaline casts is amyloid change of the kidney due usually to suppuration, and with a good prognosis if the source of suppuration be removed. Epithelial, granular and fibrinous casts indicate acute inflammation of the renal tubules, the epithelial cast pointing to the mild stage; that is, one of mere desquamation with urine slightly under normal in amount, specific gravity 1,030, high color, albumen a trace, numerous hyaline casts, free blood and renal epithelium. This may go on to brown or pale granular casts with diminution of the solids of the urine. The fatty and waxy casts when numerous and persistent indicate long-continued chronic inflammation of the kidney with bad prognosis. Blood and epithelial cells are absent. In this case the urine is diminished in amount with increased specific gravity. The pale, granular and small hyaline casts point to fibroid kidney. Aside from the microscopical appearance, the general condition of the patient, age, sex and previous history must be taken into consideration. It should be remembered that the diagnosis of cases alone may mean little, but the kind of casts in abundance is the important point.—*Maryland Med. Jour.*

Gold Mines in Cemeteries.

A writer in *Le Temps*, of Paris, has been traveling in America, and, of course, relates his "impressions." What struck him particularly was not the Falls of Niagara, the inquisitiveness of reporters, or the consumption of pie, but the fillings in American teeth. He has consulted the statisticians and finds that the amount of gold annually pounded into our dental cavities reaches the respectable figure of 800 kilogrammes, representing a value of half a million dollars. All this precious metal is buried with the Yankees

when they die, and consequently at the end of three short centuries the cemeteries of the United States will contain gold to the value of $150,000,000. He thinks this will prove too tempting to the practical mind of the future American, and foresees the day when companies will be organized to mine the cemeteries and recover the gold secreted in the jaws of deceased ancestors.

SURGERY.

Effects of Castration on the Female Voice.

The author, Moure, (*Univ. Med. Jour.*) calls attention to the effects of castration in in the male upon the voice, and to the physiological relations between the pharynx and the genitalia. He also narrates two cases of women who, after the removal of the ovaries, showed a marked lowering of the timbre of the voice, which, at the same time, became much stronger. He does not believe that such changes are constant, nor that it is easy to recognize them when they actually do occur, except in vocalists, and especially in the soprano with a high range. It is well known that castration, after a certain age, has no effect upon the larynx.

[We believe that in the latter remark is suggested the gist of the whole matter. Castration after puberty in either sex, probably has no effect whatever upon the voice. We know of one instance—a young married woman of thirty, with a fine voice—who after removal of both ovaries, found her vocal ability unimpaired].

Primary Carcinoma of the Body of the Uterus.

The last meeting of the Obstetrical Society was a specially interesting one. After Mr. Targett's demonstration of hydatid disease of the pelvic bones, consisting of numerous photographs thrown on the screen showing the peculiar eroding effect of the disease on the cancellous tissue and—a point of morphological importance—the external budding of the secondary cysts from the walls of the parent one, Dr. Lewers related a case of primary carcinoma of the body of the uterus in which vaginal hysterectomy had been performed more than two years ago without any recurrence of the disease. Five other cases were also tabulated. In cases of doubtful diagnosis Dr. Lewers justified the complete investigation of the uterine cavity by dilatation of the cervix, rather than the usual method given in text-books of waiting for the development of symptoms, so that the disease might be dealt with at the earliest possible period. The difficulty of extracting the uterus in nulliparous women, in whom carcinoma of the body is most frequently met with, was specially noticed. In the case described, it was necessary to widen the caliber of the vagina by incision of the recto-vaginal septum, and bring away the excised uterus by means of a pair of forceps devised by Dr. Heywood Smith, resembling small midwifery ones. Dr. Lewlers now adopts pressure forceps instead of ligatures for securing the broad ligaments. This formed a subject of discussion among the subsequent speakers, some expressing a decided preference for ligatures.—*London Lancet.*

Treatment of Fistula in Ano.

Dr. Geo. J. Cook, in *Mathews' Medical Quarterly*, says that ingenious surgeons in all ages have tried the cure of fistula without the use of the knife, because of the public prejudice against such radical procedure. Plasters, salves, ligatures and the many other methods for a cure have been resorted to, and it is only in the very recent past that the use of the knife permanently took their place as a curative measure certain in its results. The method of operation is as follows:

The sphincter is stretched, the rectum cleansed with a bichloride of mercury solution, and the fistula opened by the use of straight scissors; after the removal of all unhealthy tissues, the opening should be closed by a single row of catgut sutures, passed, by means of a curved needle, entirely beneath and around the wound. By this method he had not failed in a single instance to have the bottom of the wound unite.

Hemiplegia Cured by Trepanation.

The following case is a striking example of the progress of cerebral surgery, especially after so many years of the original injury. The case is reported by Leyden to the Berlin Medical Society, as follows:

A man thirty years of age is brought to the hospital in an unconscious state with hemiplegia. When consciousness was restored it was ascertained that for two years he was subject to Jacksonian epilepsy with loss of consciousness, which lasted about ten minutes, and reappeared three or four times a year. A fortnight before his entrance into the hospital he was attacked by violent cephalalgia on the left side, accompanied by somnolence and a state of stupor; the left side of the body became very feeble and was finally completely paralyzed.

It was also ascertained that at the age of four years, *i. e.*, 26 years before, he fell from a stairs and had his head injured. As a consequence, the diagnosis of Jacksonian epilepsy of traumatic origin, was made. In fact, on examining the patient there was found on the right half of the head near the median line, a depression which corresponded to the region of the central convolutions. Hence, trepanning was done, which showed nothing abnormal on the part of the brain. The wound was closed, and fifteen days later the patient was cured of his hemiplegia. The epileptiform attacks have not reappeared during the last four months. —*La Tribune Medicale.*

Aseptic Drainage Tube.

Dr. J. H. Kellogg (*Modern Medicine and Bacteriological Review*) calls attention to the fact that in drainage after abdominal operations, infection may occur through the entrance of air into the abdominal cavity in the process of removing fluid from the drainage tube by means of the evacuating syringe. To prevent this, he first devised what he terms an aseptic drainage tube, which he so arranged that the air which rushes in to take the place of the fluid withdrawn has been first filtered by passing through cotton and then washed by passing through an antiseptic solution. More recently he has simplified this devise by inserting into the drainage tube a hollow aluminum plug over which is slipped a thimble, connected with two tubes, one of which is attached to the evacuating syringe, the other to a funnel filled with absorbent cotton and covered with sheet lint. The wound should be dressed with guaze impregnated with a powder composed as follows:

Camphor	1 part.
Carbolic acid	1 part.
Boric acid	16 parts.

For the purpose of washing out the abdominal cavity subsequent to closure at the operation, it is only necessary to remove the filtering funnel by disconnecting it from the plug to which the funnel is attached and substituting a tube of proper length, the other end of which is made to dip into a solution of boric acid or whatever antiseptic may be employed. It is, of course, necessary to fill the tube with water before connecting it with the plug so that any unsterilized air which it might contain will not be drawn into the abdominal cavity. This appears to be a useful device, well worthy of professional attention.

Sprains and their Appropriate Treatment.

Primrose (*Canadian Practitioner*) holds that the aim of treatment for sprains is the early absorption of effused material and the prevention of adhesions. For the immediate treatment of a recent sprain pressure is of paramount importance. This should be applied as follows: The joint—say the ankle, for instance—is placed at a right angle (or, if possible, at less than a right angle) with the leg, then cotton-wool or ordinary cotton batting is applied evenly over the foot from the toes upward to the middle of the leg. The amount of wool must be considerable, loosely applied, it should be fully three inches in depth. Over this is applied the bandage from the toes upward, which is drawn as tight as possible. There is no danger of making too much pressure, provided there is sufficient cotton wool. This usually alleviates pain immediately by affording pressure to the blood-vessels and keeping the part at rest. The bandage and wool are removed at the end of a few days, a week at the longest, and carefully instituted passive movement is employed; then the dressing is reapplied to prevent further effusion. In ten to fourteen days cotton wool may be dispensed with and the support of an ordinary flannel roller substituted. The patient is able to use the injured joint for ordinary purposes after the lapse of about three weeks in the majority of severe sprains. In sprains of slight severity massage may be begun at once with excellent results, and in old sprains massage is by far the most appropriate treatment and indispensable in order to effect a cure. Heat and cold are at best temporary methods of relieving congestion, and do harm if employed to long.

Vaccination by Scraping a Defective Process.

Ortega, (*Bull. Glende Therapeutique.*) The author, who practices medicine on the frontier of Mexico, states that he has observed that most of the North American people are vaccinated by this process, and that a great number of the latter, although bearing a large and deforming cicatrice, contract smallpox, or can be successfully vaccinated by puncture. On the contrary, among those vaccinated by puncture very few suffered from the contagion, while revaccination was only successful in a few cases.

As these observations were made on both Mexicans and Americans, the author concludes that the race has no influence on the receptivity, and that vaccination by scraping or scarifying increased the chances of the introduction of the germs of suppuration, which although they produce inflammation and cicatices, have nothing to do with vaccine, which they destroy; while, with the puncture made on various places, a very slight opening is offered for the accessory inflammation, and the virus of vaccine has more chance to develop. The vaccination by puncturing is very seldom followed by those large inflammations which accompany too frequently the other mode of inoculation.

The process of vaccination by puncture is recommended by the New York Biological and Vaccinal Institute, but it is well to add that on account of the very slight incision made in the integument, the quality of the virus must be as near perfection as possible.

Indications for Plaster of Paris Jacket.

Dr. B. F. Wooding, *Denver Medical Times*, says: A plaster of Paris jacket is indicated in all cases where a fixed supporting dressing is needed to hold the vetrebral column in as near a normal position as practicable, whether the deformity is caused by a fracture or some active pathological changes taking place in the bodies of the vertebræ.

The most frequent use of the plaster of Paris jacket will be found in treating abnormal curvatures or angular deformities of the spinal column, produced by a so-called Pott's disease or caries of the bodies of the lumbar or dorsal vertebræ.

In diseases and injuries of the cervical vertebra the cast will be used as a [illegible] sert the upright support of the [illegible]

which to suspend the weight of the head, thereby taking the weight off the cervical vertebræ.

In relieving the vertebræ of their weight we allow nature to build up and restore, under the most favorable circumstances, the destroyed or disintregrating tissues.

All curvatures, whether antero-posterior or lateral, produced by irregular muscular contraction, not amenable to treatment by gymnastics, should be suspended until the normal curvature of the spinal vertebræ is restored as nearly as practicable, which requires two to five minutes, and then a plaster of Paris jacket applied.

Treatment of Uterine Deviations by Faradization.

Regnier (*Societe d' electrotherapie*): Despite accumulated proofs of its efficaciousness the electric treatment of uterine deviations is rarely used. There is no known method of producing contractious of the uterus which may not be satisfactorily replaced by abdomino-uterine, lumbo-uterine, lumbo-pubian faradization, which is little, if at all, painful. For retroversion, or retroflexion, uterine faradization is indicated; for ante-rversion, sacro-uterine faradization. The length of each application is three minutes; the number, three a week at the beginning of the treatment, and two at end. The treatment should not begin until three days after the end of the menstrual period. The intensity must be sufficient to make the contractions slightly perceptible to the hand which holds the uterine electrode. The induction coil used must be made of thick wire. The interruptions should be frequent. The length of treatment varies from ten to twenty sessions, rarely more. It should be longer in versions complicated by flexions, and in cases accompanied by vaginal and perineal lesions.

Steam as a Hemostatic.

Professor W. F. Snegirew of Moscow, reports the successful use of steam for hemostatic purposes in several cases where other means have been unsuccessful or inconvenient. His attention was called to the possibility of using steam as a general hemostatic, as the result of a severe hemorrhage occurring during an operation on the liver. On reading the literature of hepatic hemorrhage he was impressed, he says, by the general helplessness of the surgeon, in such cases. "Even the actual cautery was not always sufficient, and in most cases required the additional aid of a closely placed tamponade of gauze."

For some time Professor Snegirew had been in the habit of using steam as a cauterizing and hemostatic agent in the treatment of uterine disease in the following manner: After dilating the uterine canal an application of steam was made through a small metal tube inclosed in a catheter. After a half, or at most a full minute of this application, a dark fluid, with a strong brothy odor, returns through the catheter. In his experience there has been no pain attending this application, and many cases of tender, painful, bleeding conditions of the uterine mucosa have been entirely relieved.

Carrying out the suggestion from this use of steam he conducted a series of experiments with Dr. Blagewolin, to determine the hemostatic value of steam upon the liver and other organs. Their results in animals were as follows:

1. They were enabled to remove, without loss of blood, such sized pieces of the liver as they chose, the animal surviving.
2. Similar results were obtained on the spleen.
3. They removed entire lobes of the lungs without hemorrhage.
4. Considerable sized pieces of kidney were successfully removed.
5. From the brain, excision of pieces up to a limited size.
6. Bleeding from the spongy portions of the bones was stopped.
7. The marrow was scalded, but the restoration of the bones went on as usual.
8. The femoral artery of a dog, cut through, either across its course or lengthwise, did not bleed under the application of steam.
9. The wounds after the use of steam healed by primary intention in animals, and also in men upon whom it was used.

As the result of these experiments, steam was used as a hemostatic during the past summer in the Alexiner Semstwo Hospital with success in the following operations:

1. In five cases of resection of the knee-joint, without elastic bands, ligatures or artery forceps.
2. In the extirpation of a cancerous breast, under the same conditions as above; also in the removal of fatty and malignant new growths in the skin.
3. In amputation of the cervix uteri and in fibromyotomy.
4. In resection of bone and in removing sequestra.
5. In abscesses, to render them odorless and induce rapid healing.
6. In fistulæ and sinusees, especially when tubercular.

There seems little doubt in the minds of the investigators that in steam they have found a hemostatic of ready usefulness, aseptic, not interferring with primary union, and above all, applicable to parenchymatous organs, such as the liver. Certainly further reports will be eagerly awaited.—Boston *Med. and Surg. Jour.*

Surgery of the Stomach.

For cancerous tumors of the stomach surgery offers us two procedures. Resection, when the pylorus is involved, and gastro-enterostomy or a junction of the wall of the stomach with the intestine. As to the respective gravity of these operations Huinard gives a mortality of 62 per cent. in 153 resections. Le Boef, 58 per cent. in 108 resections, while Kocher had but two deaths in seven resections.

For gastro-enterostomy Guinard found reported 105 cases with 33 deaths. Rockwitz had but a mortality of 12.50 per cent., and the results of Hahn are better yet. Resection, then, is always a more grave operation than gastro-enterostomy. The contra indications are, first, great extent of the neoplasm; second, adhesions between the stomach, pancreas or liver; third, injection of the amentum; fourth, cancerous infection of the lymphatic-ganglia. As to the results of these operations, there can be no doubt but resection leaves more functional power, as the motor action of the stomach is but slightly impaired, while in gastro-enterostomy, it is quite suspended. In cicatricial contraction, resection should be the operation of choice, without malignant complications, while in extensive cancer gastro-enterostomy is the safest and most satisfactory as a palliative measure.

As for the treatment of round ulcer of the stomach we must take three factors into consideration: First, hemorrhage; second, peritonitis, and third, by perforation. Operations for hemorrhage, thus far, give us but little hope to expect much from them. Operations for peritonitis following perforation give a mortality, in 15 cases, 14 deaths.

Treatment of Epithelioma of the Face.

A. Darier (*Bul. Gen. de Therapeutique*), after having used chlorate of potassium, acetic acid, aristol, resorcin, etc., the author has adopted the following treatment: 1. The sore is well washed. 2. A solution of 10 per cent. of cocaine is applied with a pledget of cotton. 3. A few minutes later, methyline blue is applied (methyl blue, one gramme; alcohol and glycerine, aa five grammes) 4. The parts colored blue are touched *very slightly* with a steel probe dipped in chromic acid at 20 per cent. A purple reaction takes place. 5. Another methyline blue is applied again and the vicinity of the tumor is washed carefully to remove the excess of color. 6. The consecutive dressing is of cotton, moistened with 1-1000 solution of bichloride of mercury, in order to avoid the formation of scabs, which would be an obstacle to the subsequent treatment. This is repeated four or five times, at intervals of two or three days, and according to the area affected the treatment is continued for a period varying from two to eight weeks. Five successful cases were exhibited before the Dermatological Society of Paris.

Hot Salt Solution for Relief of Shock and Hemorrhage.

Dr. Wyeth, speaking at the meeting of the New York State Association of Railway Surgeons, strongly recommended the injection into the circulation, through a vein, of hot salt solution to take the place, in part, of the volume of blood which has been lost as a result of accident: "The solution which I have employed, running in as much as five pints in a single operation, is composed of clean water, which has been boiled and allowed to cool to 110° or 120° F., or just as hot as the hand can bear, to every pint of which a teaspoonful of common salt is added. I have seen the pulse go from 140, in cases of tremendous hemorrhage, steadily down to 70 to the minute, within two minutes of the injection of a pint of this solution. While it may be used cooler than 110° F., and in some emergencies this may be necessary, it is safer to give it as hot as 110° to 120°, because the cold solution robs the body of its heat, while the hot solution carries heat with it, and thus adds to the maintenance of the normal temperature. The apparatus is simple, a metal or glass pipette to go into the vein, a rubber tube three or four feet long and an irrigator bag or vessel."

Insufflation of Air for Tuberculous Peritonitis.

M. H. Follet of Lille highly recommends the insufflation of air into the peritoneal cavity in cases of tuberculous peritonitis. He maintains that when laparotomies are performed for this condition, the great relief which almost invariably follows comes through ingress of fresh air, which sets up a reactionary inflammation of the serosa, that ends in the breaking down and resorption of the tuberculous masses.

He cites remarkable cases wherein the parents of a child of ten would not consent to a laparotomy. He introduced a trocar and drew away three liters of serum and then insufflated with three liters of air into the cavity of the peritoneum. Recovery was prompt and there was no relapse. Moorhoff of Vienna treated a case of tuberculosis of the epididymis by this plan with success in 1892.

He concludes by advising that when there are contra-indications to laparotomy, this is the course to pursue, as it is not dangerous, and usually succeeds.—*Le Mercredi Med.*

Endometritis and the Gonococci.

In the *Medical Fornightly* Dr. W. H. Humiston says:

During the past few months in every case of marked disease of the tubes and ovaries that has come to my clinic at The Western Reserve Dispensary, we have been able to not only find an active endometritis present, but on examination of the secretion from the cervical canal have found the gonococci of Neiser. This is confirmed by the observations I have made in my private work in all those cases that have been suffering from uterine disease but a comparatively short time yet have swolen tubes and ovaries, and evidences of pelvic peritonitis. Cases not gonorrhœal in origin may have been suffering from endometritis for a long period, yet there is no appreciable involvement of the tubes and ovaries. These facts are important, and lead us to a realizing sense of our great responsibility in making an early diagnosis as to the etiology of every case that first consults us. If it be of gonorrhœal

origin the symptoms will generally come on quite suddenly, and are so marked that a diagnosis may be inferred, but it is always best to make the routine test for gonococci and be certain, for in some comparatively mild cases of vaginitis and endometritis you will find them present, and by adopting active, thorough treatment, you will prevent the extension to the tubes and ovaries. These septic cases must be treated on modern surgical principles, *rest*, *asepsis* and *drainage* with *curetting*. When these cases are diagnosed early and the proper treatment instituted, the abdominal surgeon will not have his belt hanging full of suppurating tubes and ovaries. Why is it? The answer is: Abdominal growths are looked for and recognized early by the general practitioner, and so will the septic cases of endometritis be diagnosed early, and its far-reaching and disastrous results averted by adopting an active, thorough treatment, as I have above indicated.

Suture of the Torn Cervix Uteri Immediately after Labor.

Severe and alarming hemorrhage from the torn cervix requires suture or ligature *en masse*. An operation to check bleeding from the uterine artery or its branches should not be called trachelorrhaphy. Lacerations of the cervix are not accountable for post-partum hemorrhage, nor are they accountable for subinvolution. The liability of an open, torn cervix to become infected is a question difficult of solution. If the confinement has been surgically a clean one, infection cannot occur. If the accouchement has been filthy, we have no right to lock up in the uterus the lochial discharge. The torn cervices of Dubosseir's incisions do not become infected. An examination of frozen sections of post-partum cases fails to show such separation of torn cervical lips as those who advocate trachelorrhaphy picture. It is difficult to tell how much of the tissue will be cervix, when involution is complete, and how much lower uterine segment or vagina, since the anatomical relations of the parts are so disturbed by the merging of the uterine and vaginal canals into one parturient tract. It is the author's belief that there is but one indication for immediate repair for the torn cervix,—hemorrhage. To do trachelorrhaphy in all cases, where even marked separation of the cervical lips appears to exist, is to introduce into obstetrics one more interfering, meddlesome, routine operation for which there is absolutely no reason; is to add more chance for infection; and is to undo what nature, at great pains and beneficently, has accomplished, viz., a provision for the free escape of the lochia. The large everted flaps of cervical tissue which we see some months after labor are not natural; but the abnormality existed before conception, has been increased by pregnancy, and demands only the operation which should have been done before conception.—*William R. Pryor, M.D., New York Medical Journal.*

Rhythmical Traction of the Tongue in the Treatment of Asphyxia.

The *Therapeutic Gazette*, gives an editorial article upon this subject. Laborde claims that this method is the most powerful and simple of all means employed against death from respiratory failure. By traction upon the tongue the diaphragm is excited to its respiratory function, the sensory impulse is conveyed by the superior laryngeal, the terminal tracheal and bronchial expansion of the pneumogastric, the glosso-pharyngeal and lingual, and the motor respiratory nerves, especially the phrenic, respond to the reflex excitation.

Traction is performed fifteen times to a minute at about equal intervals, the tongue being pulled out sharply, so that its whole body, and not merely the tip, is affected. Traction should be kept up at last thirty minutes. Mechanical artificial respiration should be applied at the same time, two assistants making pressure simultaneously, the first upon the sides of the chest and the second upon the epigastric region from below upward. The pressure is fifteen times to the minute, and at the moment when traction upon the tongue is relaxed.

By order of the Prefect of Police, notices giving the method of Laborde have been printed and posted in the life-saving stations throughout Paris.

The first case in which rhythmical traction of the tongue was employed in Paris was by Mr. Lapicida (*La Tribune Medicale*,) chief of the corps of the life-saving station. A young woman, attempting suicide, jumped into the Seine, and remained submerged for five minutes. When rescued frictions were applied, but without success; but after rhythmical traction of the tongue for five minutes respiration was established.

An interesting case is related (*La Tribune Medicale*,) of apparent death from violent shock by an electric current of a strength of more than two thousand volts. The hand of the patient was burned and his body was black. Rhythmical traction of the tongue was made for more than an hour, when natural respiration was re-established.

Prostatectomy.

Lagoutte (*Gazette Hebdomadaire de Medecine et de Chirurgie*), after an elaborate review of the operations for enlarged prostate, comes to the conclusion that it is only applicable to extremely few cases. The good results of the operations he claims are due mostly to the fact that the bladder has been drained and not to the removal of any obstruction. Excisions of parts of the prostate are satisfactory only where there is a middle lobe that is pedunculated and easily removed or enucleated. In operating by the perimeal route the large tube introduced is often a source of great distress, and cannot be borne, and in the larger number of cases the disease again causes obstruction. He advocates the employment of the simple suprapubic cystotomy of Poncet. These cases occur in patients much debilitated and un-

desirable subjects for long bloody operations, and he urges the employment of the simplest quickest means which will give the patient comfortable and satisfactory urination.

The Circulation of the Lymph in the small Lymphatic Trunks.

Ranvier has succeeded in injecting Prussian blue into the capillary network and small lymphatics in the ear of a living rabbit. The injection gave no pain nor any disturbance of the blood circulation; the course of the injection could be plainly seen. The color in the lymphatic trunks became paler and disappeared in two or three minutes, while the network of the lymphatic capillaries was still blue. This is due to the activity of the lymph circulation and not to decoloration in situ. Further the coloring matter was found in the ganglion at the base of the ear.—*Prog. Med.*

Pott's Disease in Children.

Pott's disease in children is so often recognized so late in its course that all hope for improvement is futile. The early symptoms and signs which should always be looked for are down by Dr. Dillon Brown in the *Archives of Pediatrics* in the following list of different points:

The pain, general disability and sickness are out of proportion to the apparent of spinal disease.

The onset is alarming and the progress of the disease is more rapid than in tubercular caries—the paralysis being an early symptom and the deformity appearing even in a few weeks after the beginning of the symptoms.

The local pain is intense; and the peripheral pains, the deformity, the extreme spinal disability and the paralysis, including incontinence of urine and fæces, rapidly grow worse in spite of rest in bed and instrumental support.

Secondary disease soon appears, rapid emaciation and marked cachexia are seen, and the patient does not live more than six or eight months.

Whether a vertebral caries is due to syphilis or to tuberculosis is of immense importance as regards prognosis and treatment. In both diseases the symptoms are almost identical, and the diagnosis must be based upon the history, the presence or absence of the evidences of syphilis, and the result of treatment. In tuberculosis there is more likely to be an evening rise in temperature, and the pus and debris may contain tubercle bacilli. Syphilis is suggested by nocturnal pains and the involopment with chronic disease of some other joint or joints or some other part of the spine.

Brown-Sequard Method.

Gibier (*New York Therapeutic Review*), after a brief review of Brown Sequard's work and the results obtained by him, reports his personal observations as to the hypodermic employment of testicular and other organic extracts. Two cases of progressive muscular atrophy and two cases of paralysis agitans showed no improvement. In two cases of cancer there was very marked improvement in the general condition. A number of other cases are cited in which the cancer cachexia was practically cured by orchitic extract.

The case of Megnin's dog is also recalled. This animal was in the last stage of cachexia produced by general sarcomatosis and was paraplegic. After three weeks of organic fluid injection he was able to climb a flight of stairs, and six weeks later was entirely cured. Ultimately the dog was killed accidentally. The autopsy showed that the many tumors of the serous membrane and the viscera had undergone fibro-calcareous degeneration Two cases of diabetes were treated with extracts from the testicles and pancreas; one was improved and the other apparently cured. One case of nocturnal emissions was markedly improved. One case of epilepsy was practically made worse. One case of Thomsen's disease (muscular spasms and trembling on the beginning of voluntary motions) was improved. In neurasthenia the results were most excellent. Several cases of locomotor ataxia were improved. One case of bulbar paralysis apparently hopeless in its prognosis was cured. Here both extract of testicle and of nervous matter were used.

A New Method of Anæsthesia.

M. M. Paul Langlois and Maurange read (*Chem. and Drug.*) a paper at the Academy of Medicine, Paris, on a new method of anæsthesia by the association of chloroform with sparteine and morphine. The object of this combination is to diminish the danger of stoppage ot the heart and fainting in anæsthesia by chloroform. M M. Langlois and Maurange state that a quarter of an hour before administering chloroform they give the patient a hypodermic injection composed of three centigrammes of sparteine and one centigramme of hydrochloride of morphine. This they have used in 140 cases, and in none of them had they the slightest anxiety regarding the heart's action. The only objection made to the paper, and it was acknowledged by the authors, was that many hundreds of experiments are necessary before it is possible to judge definitely regarding the utility of the method.

Incontinence of Urine.

Dr. White's formula is:

Benzoate soda.....	
Salicylate soda.....āā	gr. xv
Ext. belladonna.....	gr. xxx
Cinnamon water.....	ʒ iv

A teaspoonful four or five times a day.

—*Archives of Pediatrics.*

Hysteria.

Rosser suggests $\frac{1}{10}$ grain of apomorphine, hypodermatically, to break up and prevent the recurrence of hysterical attacks.

Double Castration Under Cocaine for Head Symptoms, etc, Due to Injury of Testicles.

Marshall (*Virginia Medical Monthly*) reports the case of a man, aged forty-seven, who had lost the power of sexual intercourse, as he supposed, from an injury by lifting The testes and cord became tender on pressure and were at times extremely painful, the cremaster contracting spasmodically and producing severe headaches. The patient's mind became greatly affected; he drifted into a melancholic state, even refusing to take food.

Marshall injected a two per cent. solution of cocaine, using in all, two drachms of the solution. He then removed both testicles. This was done without pain. The results of the operation were highly satisfactory. The pains were cured and the head symptoms disappeared, the patient's mind remaining perfectly clear.

The Flap Method of Operating.

Chiene advocates the more general use of the flap method of operating. It consists in exposing a part by means of a flap instead of making a direct incision down to it. The advantages claimed are that the wound in the deeper parts is at a distance from the skin wound, the skin over the deeper wound is not interfered with; it supports the deeper tissues which have been divided, and rapid healing takes place. The flap is composed of skin and subcutaneous tissue. It should, as a rule, be crescentic, and not horse shoe shaped. The incision should be made as far as possible from sources of septic infection. The main blood-supply should enter the base of the flap; this, however, is secondary. He recommends its use in the removal of loose cartilages from joints, in operations for hernia, in excision of the knee, in the removal of tuberculous glands, operations on the tendons, and in many other cases.—*Brit. Med. Jour.*

Acetanilid as a Surgical Dressing.

At a recent meeting of the Philadelphia County Medical Society, Dr. Thomas S. K. Morton read a report of the use of acetanilid in surgery, based upon his observations in an extended hospital and private practice. The results were so exceedingly favorable that he recommended its general adoption. In all operation on wounds, including amputations, used as a dusting powder, it promoted healing without suppuration. Its effect was to thoroughly dry the wound so that the usual drainage tube was not necessary. In cases of scalds and burns it dries and soothes the affected surface, allowing healing to take place rapidly. As a dressing to chronic sores and ulcers it proved superior to other dressings. But two cases of constitutional effects were observed, one in his own practice and one reported by a surgeon in California; and, in both, the powder was applied over a large area in cases of extensive burns. Neither case was fatal.

Acetanilid is very cheap, being at present only forty cents per pound. It is colorless and non-odorous. It is soluble in five parts of alcohol, and in four-tenths parts of boiling alcohol; in 194 parts of water at 59° F., and in eighteen parts of boiling water, in eighteen parts of ether, in equal parts of chloroform, and in the various petroleum oils in the proportion of forty grains to the ounce. In powder form it may be mixed with pulverized starch, boracic acid, or, if an alkaline powder be desired, bicarbonate of sodium. The best preparations are as follows:

For dusting powder, pure acetanilid, or one ounce of acetanilid to two to four ounces of starch, freely triturated; for a solution, one drachm of acetanilid dissolved in five drachms of alcohol, to which add about eight ounces of boiling water and let cool; for an oily solution, forty grains of acetanilid to one ounce of liquid petrolatum; for an ointment, forty grains of acetanilid to one ounce of petrolatum; for a collodion, forty grains of acetanilid to one ounce of collodion. These proportions will be modified by the practitioner to suit particular cases as his experience advances.—*Indiana Med. Jour.*

Traumatic Glycosuria.

Glycosuria in any form is always an interesting study but ever since the experiments of Claude Bernard on this subject the study of traumatic glycosuria has occupied scientific attention more or less. Drs. F. A. Higgins and J. B. Ogden have made observations on 212 cases of head injuries in the Boston City Hospital and their conclusions as laid down in the *Boston Medical and Surgical Journal* are exceedingly instructive. They are:

1. That, after injury, sugar may appear in the urine as early as six hours, and disappear within twenty-four, the average time for its appearance, however, being from eight to twelve hours; for the disappearance of the same, from the fifth to the ninth day.

2. That a small proportion of the cases may exhibit a permanent glycosuria from the date of injury to the head.

3. That acetone and diacetic acid are rarely if ever found in such cases, excepting where the condition becomes a permanent glycosuria, and even then probably only after a number of months or years.

4 That of the 20 sugar cases here recorded, 11 (55 per cent.) had received an injury to the right side of the head; 5 (25 per cent) to the left side; 3 (15 per cent.) to the occiput, and 2 (10 per cent.) where there was no external evidences of violence.

5. That it is impossible in the present state of the knowledge of the pathology of diabetes and glycosuria to draw any inferences from the autopsies which have been obtained. It was thought best, however, to report them in full.

6. That there is little to be said in regard to the mortality. Of the 20 cases, 8 died—6 being the direct result of severe injuries, 1 from intercurrent disease, and the third probably from alcoholism. In the 212 cases, 16 were fatal, 50 per cent. of these having glycosuria.

Septicemia.

Septicemia after childbirth and particularly after miscarriage is a very dangerous complication. Dr. D. Rose gives his method of treatment of such cases in the *New York Medical Journal*. He wipes out the uterine cavity until the borated cotton comes away odorless and then he applies iodized phenol to the interior of the uterus. This he repeats daily, if necessary, and also gives internal medication. This method of treatment is attended with no pain, no risk, and in his hands has been uniformly successful.

Movable Kidney.

De Renzi (*Brit. Med. Jour.*), in a clinical lecture on a case of movable kidney, says that in the physical examination of such cases he prefers the lateral to the dorsal position. Movable kidney is often associated with dilatation of the stomach; this is either a mere coincidence, or due to pressure on the duodenum, or a reflex neurosis. Glenard believes that movable kidney is only part of a general prolapse of the abdominal organs due to loosening of the various ligaments. In De Renzi's case there was also prolapse of the stomach with slight dilatation and slight prolapse of the uterus. In cases where there is evidence of a more or less general prolapse of the abdominal organs, surgical interference for the movable kidney is always insufficient.

ARMY AND NAVY.

CHANGES IN THE U. S. MARINE HOSPITAL SERVICE FOR THE FIFTEEN DAYS ENDING APRIL 15, 1895.

Purviance, George, Surgeon: detailed as Chairman Retiring Board for physical examination officers of revenue cutter service, April 8, 1895.

Austin, H. W., Surgeon: detailed as member Retiring Board for physical examination officers of revenue cutter service, April 8, 1895.

Carter, H. R., detailed as Recorder Retiring Board for physical examination officers of revenue cutter service April 8, 1895.

Glennan, A. H., Past Assistant Surgeonl granted leave of absence for three days, April 9, 1895.

Stoner, J. B., Past Assistant Surgeon: when relieved to proceed to Philadelphia, Pa, for duty, April 5, 1895.

Guiteras, G. M., Past Assistant Surgeon: granted leave of absence for six days, April 5 and 8, 1895.

Perry, J. C., Past Assistant Surgeon: to proceed to Portland, Ore., and assume command of service, April 5, 1895.

Eager, J. M., Past Assistant Surgeon: to proceed to Gulf quarantine station for temporary duty, April 5, 1895.

Stewart, W. J. S., Assistant Surgeon: to proceed to Philadelphia, Pa., for temporary duty, April 9, 1895.

Norman, Seaton, Assistant Surgeon: to proceed to Norfolk, Va., for temporary duty, April 9, 1895.

Cumming, H. S., Assistant Surgeon: to proceed to Boston, Mass., for temporary duty, April 9, 1895.

NEWS AND MISCELLANY.

Northwestern University Woman's Medical School.

CHICAGO, April 13, 1895.

At a Meeting of the Faculty of the Northwestern University Woman's Medical School the following resolutions were unanimously adopted and ordered to be placed before the Illinois State Board of Health:

WHEREAS, On three occasions within the past three years, the Illinois State Board of Health has licensed to practice medicine in this State, students who have not properly qualified themselves for such duties, and whose incompetence has compelled us to withhold the degree of Doctor and Medicine, and

WHEREAS, By common report we are informed that the State Board has adopted a similar policy with reference to numerous other persons; therefore,

Resolved, By the Faculty of the Northwestern University Woman's Medical School that the State Board be requested hereafter to make its examinations so rigid that persons incompetent to obtain the degree of Doctor of Medicine from first-class medical colleges cannot obtain license to practice from the Illinois Stated Board of Health.

Resolved, That the State Board of Health be urged to do all in its power to secure a modification of the State law so that the privilege of examination for license to practice in this State can only be obtained by graduates of recognized Medical Schools in good standing.

Resolved, That for the protection of the life and health of our people we believe it the duty of the State Board of Health to do all in its power to prevent the entrance into the medical profession in this State of any persons not properly qualified; and

Resolved, further, That in the interests of humanity and medical science we believe the State Board should make its standard of qualifications as high as that of the best medical college in this country and that it should do all in its power to aid and encourage the efforts of the profession and the people for thorough medical education and higher requirements of licentiates and for the degree of Doctor of Medicine.

MARIE J. MERGLER,
Secretary.

Jefferson Medical College Reunion, Class of 1874.

It is proposed to have a reunion of the class of 1874 of the Jefferson Medical College, on the evening of May 10th, in Philadelphia. Members of the class who have not received an announcement will please forward their names to E. E. Montgomery, 1715 Walnut Street, Philadelphia.

THE
MEDICAL AND SURGICAL
REPORTER.

No. 1992. MAY 11, 1895. Vol. LXXII—No. 19

ORIGINAL ARTICLES.

THE NEUROTIC ELEMENT IN PULMONARY CONSUMPTION.*

THOMAS J. MAYS, A.M., M.D.,† Philadelphia, Pa.

That disorder of the nervous system plays a prominent part in the production of pulmonary consumption I have long been convinced, and in the various papers which I have written on this subject during the last seven or eight years I have made an effort to show the data on which this theory rests, and in response to the kind invitation of your secretary I appear before you to-day for the purpose of calling further attention to this interesting subject.

I am by no means the first advocate of the nervous theory of pulmonary consumption. As far back as 1842, Cheneau ("De l'Influence de la hautième paire dans la Production de la Phthisiè," Paris, 1842) attributed this disease directly to disorder of the pneumogastric nerves, and indirectly to an abnormal condition of the central nervous system. In 1850 Dr. J. C. Holland defined pulmonary consumption as a disordered condition of the nervous system. Dr. Copland regarded tuberculosis and scrofula as being dependent on abnormal conditions of the nervous system, and believed that the accompanying disturbances of digestion, assimilation, circulation, and even the local determination of these diseases are traceable to the state of the nervous influence of these parts. Laycock, in his clinical lectures on Physiognomical Diagnosis of Disease (*Medical Times and Gazette*, 1862, p. 205) says that "defective pneumogastric innervation consequent upon a loss of cerebro-spinal power is a very common predisposing and exciting cause of phthisis." Dr. Clifford Allbutt, in discussing the pathology of a variety of phthisis, states (*Medical Times and Gazette*, Vol. II., p. 613) "The more, however, I study the relations of the disease, the more I am satisfied that the lung mischief is also a neurosis—by which I mean, that the lesion is one not originating in the local tissues, but in the nervous system." Dr. Clouston, in his recent work "The Neuroses of Development" says (p. 92), that "facts seem to show that if tuberculosis cannot itself be called a neurosis it is in most cases dependent for its existence on a trophic neurosis, or bears the closest affinity to it."

From this it will be seen that this subject has interested some of the most prominent minds in the medical profession during the last fifty years. Indeed, when the richness and fertility of this field of study is surveyed, one is astonished to find how completely it has fallen into abeyance at the present time. It is practically forgotten, yet I believe that a full and thorough examination of its premises

*Read before the Section on Neurology and Medical Jurisprudence of the American Medical Association, at its meeting in Baltimore, May 7, 1895.

† Professor of Diseases of the Chest in the Philadelphia Polyclinic, and Visiting Physician to the Rush Hospital for Consumption in Philadelphia.

will give us proof of the most convincing character that it is the only key to solve the complex etiology of the disease under consideration.

At the very outset I would lay down the proposition that any agent or influence which has the power of disordering of or interfering with the integrity of the respiratory nerves in particular, or with the nervous system in general, also has the power of producing pulmonary consumption and other forms of lung disease. Thus in a recent canvass of the pathological literature of this subject, I found the records of over a hundred cases of phthisis in which the pneumogastric nerves, or the respiratory centres, were compressed or injured or diseased in connection with syphilis, alcoholism, diphtheria, measles, diabetes, multiple neuritis, locomotor ataxia, bulbar paralysis, tumor of the pons and medulla oblongata, etc.

Phthisis follows in the wake of many nerve poisons. Mercurial tremor and paralysis are well known, but the investigation of Kussmaul develops the fact that the majority of those who suffer from *mercurial intoxication*, as looking-glass gilders, mercury miners, etc., are very liable to do, also fall victims to pulmonary consumption. Even the vitality of the offspring of those who suffer from mercury intoxication is vitiated, for it is said that scrofula, rickets and pulmonary consumption are exceedingly prevalent in the children of those who are engaged in mercury manufacture; and that it induces abortion and still-births among female employèes.

Dr. Bäumler cites an interesting instance of mercurial intoxication in a family. Male, aged sixty-nine, became a gilder when thirty-nine years old and worked at it for twenty-five years, when he was compelled to seek other employment on account of serious mercurial poisoning. He was well and worked for twelve years, when he became salivated, suffered from stuttering, tremor, loss of memory, shedding of teeth, etc. He was married three times and all his wives followed the occupation of gilding. From the first union there were four children, one of whom died of gangrene of both feet, and the other three and the mother died of consumption. From the second union there were two children who, with their mother, died of consumption. From the third union all the children who were born before the mother was employed in gilding were well; while one who was born after this period was a weakling and died of cause not given, but the mother died of consumption.

Lead is another metal which has the power of deteriorating the nervous system and of provoking pulmonary phthisis. Statistics show that the disease is from two to three times more prevalent among lead workers in Wales than it is among farmers living in the same locality, or among the general population of England and Wales.

Among the agents which are most potent in the production of phthisis, I would place the abuse of *alcohol*; and I would call the attention of those to this subject who are directly engaged in the study of inebriety. I know that my friend Dr. Crothers has already made some valuable contributions to this question, and I hope to hear of his further experience in this direction to-day. It is well known that this agent exerts a poisonous influence on the nervous system, and especially on the peripheral nerves. Very frequently the nerves do not show any marked changes, but on closer examination evidence of parenchymatous degeneration with more or less interstitial neuritis is discovered, suppression of the catamenia in women, paralysis of respiration and of deglutition and disease of the vagi and of the lungs are also observed to be of common occurrence.

Syphilis is another nerve poison which is often the unsuspected cause of pulmonary disease—the typical pathological changes of which are an abundance of interstitial connective tissue proliferation, peri-bronchial induration, diffuse thickening of the lobular parenchyma, syphilitic gummata and nodular induration or broncho-pneumonia. The poison seems to attack the cranial in preference to the peripheral nerves. That the vagi are frequently implicated is shown by a number of cases among my collection.

Whooping Cough is preëminently a specific spasmodic affection of the respiratory nerves. Hufeland, Hoffmann, Wendt, Walshe and Puldame ascribe its principal lesion to irritation of the pneumo-gastric nerve. The pulmonary changes of whooping cough are interesting because they show the direct relationship between the disease of a nerve and that of the organ

which it supplies In all severe cases there is congestion of the pharyngeal, laryngeal and bronchial mucous membrane and of the lungs, together with dyspnœa and feebleness of the respiratory sounds. There may also be a shade of dulness in some parts of the lungs. Epistaxis, hæmoptysis, emphysema, chronic bronchitis, broncho-pneumonia and consumption are frequent complications, especially in the offspring of those who bear a history of chest disease.

Whatever the precise etiology of *influenza* may be, it is essentially a disease of the nervous system. Its morbid anatomy is principally seen in the meninges of the brain, spinal cord, and peripheral nerves. Pulmonary œdema, broncho-pneumonia, capillary bronchitis, and pleurisy are among its common sequela. The pulmonary disease was believed by Graves to be due to paralysis of the vagi, and Walshe says this poison seems to exert a special influence on the pneumogastric nerve.

Cerebro-spinal meningitis—an affection which chiefly involves the medulla oblongata and its immediate connections—is nearly always associated with pulmonary derangement. Then there is another group of diseases—the most prominent of which are *beri-beri*, *pellagra*, *diabetes* and *leprosy*—in which disease of the nervous system and disease of the pulmonary organ play a prominent rôle.

Epilepsy is also a disease in which the medulla oblongata is involved, and it is in the latter area that we will have to seek an explanation for the ultimate and long-recognized association between this disease and pulmonary disease. Echeverria. in his work "Epilepsy" states (p. 313) "I have most closely investigated the relation of pulmonary tuberculosis and epilepsy, and undoubtedly the genesis of tubercles in the lungs is favored by the lesion in the medulla oblongata proper to epilepsy. I have traced the pulmonary trouble from its inception and feel convinced that the association is more than a casual coincidence of both morbid conditions. Besides Echeverria, Van der Kolk, Jobert de Lambelle, Stuart Cooper and Rostan reported a number of cases of epilepsy associated with pulmonary disease in which the pons varolii, medulla oblongata and vagi were disordered.

Asthma is a spasmodic affection of the pneumogastric nerve and it is therefore of great interest in this connection to find whether this disorder develops into more serious lung disease or not. Asthmatics are generally supposed to be long lived, but I do not believe there is much clinical evidence to support this belief. Of course there are some exceptional cases which undergo spontaneous cure in the later years of life, but in the majority of these sufferers the attacks incline to become continuous and it is to these my remarks refer. I believe that the tendency in such is a termination in pulmonary consumption. In support of this Fuller ("Diseases of the Chest") states that, in spite of the belief that asthma and pulmonary consumption are antagonistic, many asthmatics die of the latter disease. Williams ("Pulmonary Consumption") shows that in 385 cases of phthisis seven began with asthma, and states that the tendency of asthmatic parents to have phthisical children is hardly sufficiently recognized. James ("Pulmonary Phthisis") asserts that asthma and whooping cough are likely to predispose to or terminate in phthisis.

Hysteria implicates the respiratory organs in the form of accelerated breathing, dyspnœa, aphonia, laryngeal and pharyngeal paralysis, etc., and has an innate tendency to develop into pulmonary disease either in the individual or the offspring. Professor Grasset ("Brain." vols. vi and vii) found that among the patients, brothers and sisters, grandparents, and uncles and aunts of 44 hysterical patients, there were 60 who died or suffered from phthisis.

Most all of these interesting cases furthermore demonstrate that phthisis may follow, or be followed, alternate with, or evolve from hysteria and other nervous disorders in the same individual. Thus in cases 2, 26, 27, 30, 42 and 43 phthisis followed hysteria; in case 4, bronchitis followed catalepsy; and in case 17, epilepsy preceded phthisis. In case 28 there was alternation between hysteria, phthisis and epilepsy; in case 29 whooping cough and hysteria preceded phthisis; in case 31 phthisis existed first, this was displaced by hysteria, after which the patient suffered from sciatica, then from boils, and in the end recovered altogether. In cases 32 and 33 there was alternation between phthisis and hysteria, and final recovery from both diseases. In case 34 the patient became phthisical, and then suffered

from hysteria during which time the phthisis improved, and in the end she became paraplegic. In case 35 hysteria came first and then phthisis, after which the hysteria abated and the phthisis progressed. In the end the patient improved. In case 36 the patient suffered from phthisis and then became hysterical. She recovered from phthisis but remained hysterical. Case 37 had phthisis first, then hysteria, after which the phthisis improved and disappeared, but the hysteria continued. Case 38 was phthisical first, then became a somnambulist, after which he recovered from phthisis. Patient 39 had pneumonia, then paraplegia, then phthisis and finally hysteria. Recovered from phthisis. In case 40 there was phthisis, then hysteria and hemiplegia, after which phthisis abated. In case 41 bronchitis appeared first, then convulsions, then phthisis and finally hysteria. Patient improved in the end. In case 44 hysteria was entirely displaced by phthisis.

Idiocy has a powerful bearing on this subject. Thus in 2,380 cases of idiocy and imbecility which were admitted into the Royal Albert and Darenth asylums in England (see Tuke's "Dictionary of Psychological Medicine," Vol. 1, p. 664) it was shown that a family history of consumption existed in 674 of the inmates, or in 28.31 per cent. Dr. Langdon Down, physician to the Earlswood Asylum for idiots states ("Mental Affections of Childhood and Youth," p. 221), that the statistics of London show that the deaths from phthisis constitute 115 per 1000 of the general mortality. His statistics at Earlswood indicate that phthisis was the cause of death in 398 per 1000 of the general mortality. His last hundred post-mortem records show that 62 were phthisical, in some of which cases there was no record of disease in the family, and he believes that in these cases phthisis was the sequence of idiocy. "Defective innervation, in all probability, led to malnutrition and predisposed to a tubercular condition." Dr. Down also contributes the histories of 20 families, each of which was burdened with idiocy, and among the parents, sisters, brothers, grandparents, uncles and aunts of which there were 35 who suffered from consumption.

The late Dr. Isaac N. Kerlin, Superintendent of the Pennsylvania Institute for Feeble-minded Children, in an essay (*Trans. Penna. State Med. Society*, 1880, Part I., p. 161) states that if the tables which he presented in this paper were prepared by a special advocate to prove that consumption is the main factor in the generation of idocy the effect could not be more startling: but "as they are the result of careful inquiry, without any theory to prove or disprove, I ask for them you respectful judgment." In the table to which he refers he gives the histories of 100 families in each of which there existed a case of idiocy, and this shows that there were 145 members of these families, only including parents, sisters, brothers and grandparents, who were afflicted with pulmonary consumption. In view of the fact that only about 17 per cent. of the general population die of pulmonary consumption this death rate is simply enormous. It means that the mortality from this disease is from eight to ten times greater among this unfortunate class than it is among the ordinary population.

Moreover, no one is surprised to find that insanity and epilepsy create a special liability to idiocy in the offspring, but it is certainly very startling, especially in the light of its supposed bacillary origin, that consumption is more powerful in this respect than any other cause which is known to lead to this disease. Thus the statistics of the Royal Albert and Darenth Asylums, already alluded to, show that among the hereditary causes of 2,380 cases of idiocy and imbecility, consumption ranks the highest, having a percentage of 28.31, while insanity, epilepsy and alcoholism have a percentage of 16.47, 8.69 and 16.38 respectively.

Dr. Down, in the work already referred to, makes the following pertinent reflections concerning the relationship which exists between phthisis and disorder of the nervous system: "It appears to me that tuberculosis must be accepted as one important cause of idiocy; that it impresses special characters thereon while imparting a strong family likeness to the subjects of this class. It is no less clear to me that idiocy of a non-tubercular origin leads to tuberculosis. Whether this arises through the influence of the pneumogastric nerve, mal-assimilation of food, or defective innervation, it cannot but be regarded that the connection between these two maladies is by no means accidental, and that a due

appreciation of this relation is necessary to those who would treat effectively congenital mental lesions.

The clinical association between *insanity* and pulmonary consumption has been noticed by many authors, among whom are Van der Kolk, Esquirol, Georget, Burrows, Ellis, McKinnon, Clouston, Boyd, Savage, Norman, Tuke, Laennac and others. Maudsley says ("Pathology of Mind", p. 113), "Perhaps I might set it down as a true generalization that the morbid neurosis, when it is active and gets distinct morbid expression, may manifest itself in four ways: (*a*) In disorder of sensation—for example, paroxysmal neuralgia; (*b*) in disorder of motion—for example, epilepsy; (*c*) in disorder of thought, feeling and will—mental derangement; (*d*) in disorder of nutrition—whereof diabetes is the earlier and phthisis is the later stage." Doctor Blandford states ("Insanity and its Treatment," p. 56), "I have found, however, that phthisis and insanity do frequently co-exist in the same family." Doctor Stearns says (*American Journal of Insanity,* 1888, p. 87), "We often see a consumptive having a child, which instead of developing consumption develops insanity, and *vice versa,* an insane person may have children of a phthisical tendency." Doctor Mosher relates an interesting case (*Medical Record,* 1895, p. 390): Female, aged sixteen, was admitted Sept. 25, 1893. Said to have been insane for eight years, and her attacks were of epileptiform nature, characterized by sudden outbreaks of violence, and probably associated with unconsciousness. Heredity was the assigned cause, eight paternal great uncles and great aunts had died of phthisis, and her paternal grandfather was epileptic in youth and neurotic. During her residence of about six months she had intractable bronchitis and laryngitis with aphonia. Clouston, in his "Neuroses of Development," makes the observation (p. 91) that the death-rate from phthisis among the insane is four times higher than among the general population, and that both diseases are very common in different members of the same family, and that heredity towards phthisis may determine insanity and *vice versa.* The same authority also remarks (Lectures on Mental Diseases, p. 461): "The form of insanity which is commonly associated with phthisis is monomania of suspicion and melancholia. Nearly all pure cases of this kind sooner or later die from phthisis. The most marked cases of phthisical insanity are those with a strong hereditary tendency to both insanity and phthisis or to the neuroses. It is surprising how often both diseases occur in different members of the same family. * * * The constitutional weakness which tends to end in insanity *is akin to that which tends to end in phthisis*" (p. 468). Schroeder Van der Kolk states (*Sydenham. Pub.* Vol. xi, p. 170), that phthisis and insanity frequently co-exist, or alternate with one another. We often see phthisis occurring in families, some members of which are affected with insanity. Doctor Busi, who collected his statistics at the asylum for the insane at Basle, makes the interesting observation (*Neurolog. Centralblatt,* 1887, p. 282), that in many cases we must regard tuberculosis and insanity as an expression of the same constitutional weakness. In fifty per cent. of his insanity cases there was tubercular heredity; in 47.2 per cent. there was neuropathic heredity, and in twenty per cent. there was a mixture of the two. On account of the frequency with which both diseases exist in the same families he believes that that there is an internal relationship between the tuberculous and psychopathic constitution.

Dr. Bianchi describes a pneumonia (*Neurolog. Centralblatt,* 1890, p. 249) which frequently occurs in paralytics, and which differs clinically and anatomically from croupous pneumonia. The temperature is usually low, cough and expectoration are sometimes absent, the respiratory movements are superficial, weak and slow, and the affected lung usually remains in a hepatized condition. Frequently there exist larger or smaller gangrenous foci, and nearly always, if the case is of long standing, a puriform infiltration of the alveoli and bronchi. All these manifestations simulate those of pneumonia which the author produced in rabbits and dogs by section and compression of the vagi. In a number of paralytics who died of pneumonia he was able to trace a primary degenerative atrophy of the vagi, and hence he believes that these pneumonias are dependent on vagus degeneration. He does not believe with Traube and Frey, that this pneumonia is engendered by the swallowing of food. (Shluck-pneumonie).

This subject is one of vast proportions

and if I had time sufficient I might inquire whether the symptomatic and the therapeutic evidence is not equally as favorable to the neurotic theory of phthisis as that is which comes from the pathological side of this question. Do not the weakness, the easy fatigue, the restless sleep, the extreme nervousness which is present in many cases, the dyspnœa, the hoarseness and aphonia, the thoracic pain, etc., indicate that the principal nature of phthisis is one of nervous exhaustion? And therapeutically is it not true that we get the best results from those measures and agents which prove to be the most efficient in the treatment of nervous diseases? And are not these rest, nutritious food, strychnine, electricity, hypophosphites, cod-liver oil, phenacetin, capsicum, quinine, and remedies which appeal to and influence the nervous system?

THE RIGHT TO QUESTION AUTHORITIES, AND THE VALUE OF MEDICAL TESTIMONY.*

JAMES W. KEISER, M.D., READING, PA.

This subject suggested itself to me at one of our meetings, where great stress was laid upon the opinions and testimony of authorities, while, to me, the drift of facts seemed to contradict these opinions and testimony. It is not for the love of disputing that I take up this subject, but with the belief that I can make some deductions which, in the future, may possibly aid us in arriving at correct conclusions.

The word *authority* does not occur in any medical dictionary in my library, so I am compelled to fall back upon Webster. His definition of authority, so far as it pertains to the subject under consideration is, "The power derived from opinion, respect or esteem." I think we are compelled to admit that anything that is published is more or less an authority. Any one of us, if we take a stand on a subject, would gladly quote anything that is printed as more or less confirmatory of the view taken. There are authorities of every kind, and each man has a preference, giving more weight to the sayings of one than of another. Even were all authorities agreed their opinions are not final, as we know that twenty years will work such havoc with our present knowledge and opinions that the books on our shelves today, will, be then, only historical memorials of the past. All future progress and revolutions in medicine will be largely made by sacrificing our present authorities. Some of these advancements will be bitterly condemned as being false, and yet in time will be thoroughly established.

On the other hand, many of these departures will be steps of error, although backed by numerous great names and apparently firmly established, and only to be finally overthrown as knowledge extends. The lesson which I wish to inculcate is that we must not too blindly worship authority; that we must reserve the right to question and weigh any proposition, no matter how strongly it be entrenched by great names.

The history of the past admirably illustrates the need of such a stand. There are startling instances in science and medicine, where a mad infatuation for the sacredness of the opinions of great men has stopped the wheels of progress and perpetuated great errors. To illustrate the value and the importance of the right to question authorities, I need not confine myself strictly to medicine. Of all great men, no one has had greater prestige than Sir Isaac Newton. As a scientist, a philosopher and a mathematician he overshadowed all his contemporaries. He did much to advance our knowledge of light and constructed the corpuscular theory, which, coming from such a source, was accepted as a fact. Living contemporaneous with him was another great intellect, Sir Thomas Young, who also made researches in light. He mathematically proved the falsity of Newton's position on this sub-

* Read before the Berks County Medical Society, March 12, 1895.

ject, advanced the undulatory theory and clearly demonstrated the truth of this theory, which is to this day universally acknowledged as correct. Yet such was the weight of Newton's authority that it was not accepted until both Young and Newton were dead and buried many years. This is an instance in which authority retarded the advancement of knowledge and perpetuated error.

Some hundreds of years ago, an epidemic threatened Madrid, Spain, and the government called a council composed of leading physicians, church and state dignitaries to consider what steps were necessary to take to avert the threatening diaster. The question arose whether the streets should be cleaned or not. They resolved that their ancestors in their great wisdom had seen fit not to clean them, that it would be impious for them to question the wisdom of their ancestors, and therefore the streets should remain dirty. The truth of this statement is attested by Buckle, one of the greatest of philosophical historians.* When this council met, Spain was mistress of the seas and of the world; but where such blind devotion to the authorities of the past was followed, it could have only one result, and that was to leave her far behind in the race of advancing civilization. To day, as the natural consequence of such a course, she is so poor that none will do her reverence.

John Hunter was, perhaps, the greatest of medical and surgical intellects that the modern world has ever possessed. His efforts and successes in the advancement of medicine, surgery and pathology were truly prodigious. He performed an experiment in which he inoculated himself with the pus of gonorrhœa and produced a hard chancre.† He, therefore, claimed that gonorrhœa and syphilis were identical. His name carried such weight and authority that this erroneous view was blindly accepted for many years after his death.

Numerous instances could be adduced where the conclusions of great men were false, and the great weight attached to their names have held back progress. There is no standard of truth or opinion which can be adopted, and the physician who will sink his own individuality when he perceives error, or, after giving a subject careful consideration, sees that the position taken by the authoritles is questionable, is not true to himself or to his noble profession if he does not take issue with what he regards as false. It is true that mistakes may be made in questioning things that do not admit of question. But it is better to make such occasional mistakes than to blindly accept everything because it is taught, and thus to destroy all independence of thought.

The value of medical testimony is practically a continuation of the subject just considered, and I wish to throw a doubt upon the value of much of the testimony given by the profession, especially where applied to the estimation of new treatments. For illustration I again resort to the history of medicine.

Many absurdities have been practiced under the guise of scientific medicine. They were sanctioned by the best medical intellects of their day, and were based on the testimony of innumerable observers. "Seeing," as the phrase goes, "is believing," and these monstrous absurdities, strange to say, depended upon the wonderful results reported as obtained by physicians in their practical application to the cure of disease. Broader knowledge and experience have wiped out much of this "truck" which was once regarded as part of the science of medicine, but I fear much still remains unsuspected by us, and that it will take much time to eliminate, if this be possible, all errors contained in our common stock of medical knowledge. I will mention a few of the absurd measures resorted to by the physicians of the past, and will briefly review some of the absurdities of our own days. I will show that, at least so far as testimony and correct deductions as to the value of treatments are concerned, we are just as apt to make mistakes as were they of some centuries ago. It is true that many errors practiced by physicians were nothing more than the abuse of valuable drugs and measures, in which the principle was extended beyond its limitations, as, for instance, the abuse of mercury, and of blood-letting.

To this day, scrofula is sometimes called the "King's Evil," and when we question, "Why this nomenclature?" the answer comes that at one time, in England, it was generally believed that the king, by placing his hand upon a

* Buckle's History of the Civilization of England.
† International Encyclopaedia of Surgery, Vol. II. P. 342.

sufferer from this disease, would banish it.* This method of cure was approved by the physicians of past days.

If any of you have a pharmacopeia which goes back far enough, you will find in it the unguentum armamentarium. The idea was that, if a weapon or object inflicted a wound, this ointment, instead of being applied to the wound, was to be applied to the weapon or object that caused the wound. Thus, if an ax cleaved a man's skull, or an ox gored a woman's abdomen, in place of applying the salve to the wound of the skull or of the abdomen, it was applied to the ax or to the horns of the bull. The wise physicians of that day, to eliminate all mental impressions of the patient, in numerous instances tested this miraculous ointment unknown to the sufferer. And the instant the application was made, the patient's condition began to ameliorate; the violent pain was assuaged; the wound began to heal and the patient made a speedy recovery! This absurdity is paralleled by the modern followers of Hahnemann. The thirtieth dilution represents a standard very much used by homœpaths. To vividly illustrate what this dilution represents, I will give you the benefit of a calculation, which I am informed was made by Sir James Y. Simpson, the discoverer of chloroform. He calculated that if, when he created Adam and Eve, God had placed in the garden of Eden one grain of arsenic diluted to the thirtieth dilution, Adam and Eve and all their descendants could have taken a dose of this preparation every minute of their natural lives, and still one-half of a grain would be left. It is almost incomprehensible that such an absurd form of medication is to this day practiced by some of our neighbors—men who can read and write, and who pose as leading citizens and gentlemen of education and culture. One would think that a man who could believe such rot would be a suitable candidate for Wernersville, where incurables only are received.

When we come down to modern times, innumerable specific methods of treatment have been adopted. The general credence given to these treatments has depended upon the testimony of many high authorities, and yet time, in most instances, has demonstrated their utter worthlessness. Koch's tuberculin, only a few years ago, caused every one to marvel at the brilliant results obtained by its use. At last consumption was met and successfully vanquished. At least such were the unanimous reports that came from every medical center of Europe. Not only was it an infallible specific in consumption, but in all the allied diseases that have any relation to tubercle. Under its use the symptoms vanished like mists before the summer's sun. All of a sudden the claims made for it collapsed, and another death blow was given to the value of medical testimony of what eminent men said they actually observed.

Then, too, there was Burgeon's specific treatment in consumption. For awhile medical journals published many cases that were reported cured by this method by honest and eminent men.

Specifics for cancer, cholera, yellow fever and other more or less incurable diseases are frequently announced, and the birth of such a specific is always attended with a report of many cures. Physicians who make these reports do not, as a rule, resort to falsehood to establish their claims, but they are carried away by their own enthusiasm and by the innate vanity to be the first to report cures of cases that are considered incurable.

Oftentimes valuable innovations are made in the treatment of diseases and of surgical conditions, but the first reports are always too sanguine. An instance is the operation of symphisiotomy. When this operation was first re-introduced, judging from the reports concerning it, any one would arrive at the conclusion that the danger of this operation amounted to but little more than that from the application of the obstetrical forceps. In spite of the first favorable reports made, a more extended experience shows that it is not devoid of danger and that unpleasant complications and sequelæ occasionally develop as a natural result of this operation.

The review of every book published, if honestly written, will disclose gross inaccuracies of statement and occasional blunders, even though the writer is of the first rank. In a standard work on surgery, I noticed that the author recommended the assiduous use of atropia in mild cases of glaucoma. Now the truth is that any physician using atropia in glaucoma would be sure to destroy sight; and its use in

* Holmes. Homeopathy and other Isms.

this disease would be good ground to recover damages in a suit for malpractice. The author who recommends this, in my opinion, stands without a peer in the surgical literature of this country.

These facts impress us with the necessity of being constantly on the alert to detect error and to scan everything to the best of our ability, so that we may discriminate properly, and select the truth. Otherwise we will be sure to make colossal blunders by occasionally selecting measures, harmful although sanctioned by men of great reputation.

It is a fact that no two authorities agree in every respect concerning any disease. Students know that in a medical college where two professors hold chairs in the same branch, satisfactory answers to questions, in some instances, depend upon which professor is making the examination. In every discussion before our society, this eternal conflict of opinions and authorities presents itself. The reason of this is obvious. Medicine is not an exact science, and for nearly every disease there are many plans of treatment, more or less helpful or worthless as the case may be. This everlasting conflict compels each physician to rely on his own judgment as to what is harmful in individual cases under his treatment. One would suppose that a drug or therapeutic measure must be of real curative value, to receive the commendations of many different observers, but daily experience tells us otherwise.

It is safe to say that before this year is over, thousands of "new ideas" will be advanced for the cure of disease. Some of these suggestions may reach the dignity of importance. Yet only a few of them will stand the test of time and experience. An honest effort to extend the armamentarium of the physician is commendable. But in these days, commercialism attempts to dictate to the medical profession, and too often are these attempts successful. Annually, hundreds of remedies are brought forward with but one idea, and that is to enrich the men who introduce them. Men with such unworthy aims systematically attempt to bolster up their preparations by the same methods adopted by the patent medicine men in general, and, alas, physicians frequently fall victims to their wiles.

In medicine, honest scepticism is absolutely necessary. To think and to question, are the natural and essential prerogatives of the physician. Any other attitude means not only mental slavery, but the overwhelming of medicine with so much rubbish as to destroy it as an art and distort it as a science. Medical knowledge has a constant tendency to increase by accumulation. As to the material offered, there is but little wheat in much chaff. With winnowing, there will be gain; without it, loss.

INEBRIETY.

WM. H. BURR, M.D., PHILADELPHIA.

In THE MEDICAL AND SURGICAL REPORTER for January 5th, an article on "Inebriety" appears, about which a few comments might be made. The article, on the whole, is a fair criticism of the prevailing tendency to cover our most common vices with the cloak of pathological dyscrasiæ. It never pays, however, to be too positive in any position that has to do with medical science, especially when the point under consideration is one that has vexed the minds and provoked the discussion of some of the ablest thinkers in the science of medicine.

What is called moral law, which is only another term for conscience and religion, will no doubt remedy many of the ills of human life, but though we apply these vigorously we, as physicians, must take into consideration all of the elements that go to make up the causation of our common failings, in order to know where our weaknesses lie.

One of the most logical writers on alcohol, whose name unfortunately we have forgotten, has said that it is the habit of the protoplasmic cells in an alcoholic to consider alcohol, either as a whole or in the form of some of its component parts, as a necessary factor in their autonomy or distribution of energy. This seems to us the most rational theory we have yet seen

as to the physical condition of an alcoholic, and explains the great difficulty which some people seem to meet with in the effort to become cured.

It will appear, however, that in the condition of chronic alcoholism there are two factors to be considered:

1. The habit of the tissues to include alcohol in their formation and distribution of energy.

2. A diminution of energy of the metabolic function, resulting also from habit.

Each cell may be said to have an individual life of its own, and to be subject to the same laws of habit, selection, etc., as is the body as a whole, though the latter may be dominated by the will and by moral law. Though will power and moral law make of the human body one of the grandest works in the animal creation, yet it results in this, that the individual cells are often more helpless than those of the simplest plant or animal.

It is unusual for the simple plant or animal organisms to take into themselves foreign or injurious substances with which they may be brought in contact, either with intention or by accident. The human body, on the contrary, is subject to all the erratic and injurious habits which it may have received by inheritance or acquired by its own vicious preference.

What is habit? Crudely speaking, the tendency to run in grooves or regularly-appointed ways.

If we accustom the muscles of the arm to do only a modicum of work, and that in the simplest manner possible, they will be found incapable of satisfying a sudden demand for greater effort. Alcohol, requiring less effort for its metabolism than its cousin starch, to just such an extent reduces the metabolic tissues to a habit of lesser activity.

The case of a man or woman who has formed the alcohol habit may be said to be similar, though in a lesser degree, to that of a person suffering starvation.

Let us suppose the case of an open boat on the pathless ocean, its occupants suffering the pangs of actual starvation. Does any one suppose that if food presented itself in any form—beast, bird, or fish, palatable or nauseous, it would be refused by the sufferers?

It is idle to reason with a person in that plight; will power, moral law, even religion may fail if opportunity offers. More than one person of the best material, being reduced by starvation, has gorged himself to death in the presence of plenty.

There is no doubt in our mind that many persons, by the simple positive assertion of will power, can at once and forever break away from a degrading and soul-destroying habit that has enslaved them for years. But will any one undertake to assert that the will power is of the same even, strong, calibre in the alcoholic as in the normally constituted individual? The alcoholic is drunk not only in his will but throughout his whole organism.

In regard to the breaking of the alcohol habit, we do not say that it cannot be done, but that it cannot be done easily. One of the best discourses we have heard for some time was a New Year sermon which deprecated the habit of taking it for granted that one could start with a clean page at the turning of the year, and could break the habits of a life time by simply making a resolution so to do. The so called clean page must necessarily be blotted with the habits and mistakes of the past, and every day ought to be a new-year day to all persons who expect to accomplish much.

There is one point upon which we wish to insist, which is that, for the confirmed inebriate, the wholesome (?) license law spoken of is a delusion and a snare.

Though the law makes opportunity somewhat less, the fact remains there is still a pretty large opportunity left, and one single little opportunity may be sufficient to start a landslide.

Personally, we doubt that the removal of the bottle from the household to the club room, hotel and corner saloon has done as much to solve the drink problem as is generally supposed. The writer in consideration himself admits that environment is the principal exciting cause of the habit of drinking, and it seems to us that the environment of a virtuous woman and fond children would have much less likelihood to encourage the sottish vice, than has the gilded saloon or the more dangerous club room.

To conclude, we wish to emphatically proclaim our opinion that the man or woman who carelessly encourages or invites a person who has been addicted to the alcohol habit to take alcohol in any form, is guilty of one of the gravest crimes in the calender, and such an act ought to be punished as would be a deliberate attempt to poison or assassinate a fellow-man.

COMMUNICATIONS.

JACKSTONE IN THE ŒSOPHAGUS: TRACHEOTOMY.

WILLIAM J. TAYLOR, M.D.,* PHILADELPHIA, PA.

A little colored boy, aged three years, was admitted to St. Agnes' Hospital on the 3d of April, 1894, with the following history: He was playing with some iron jackstones when he suddenly began to cough and to struggle for breath. He was seen by Dr. Theo. Sprissler a short time after the accident, who, although no one had seen the boy put the jackstone in his mouth, was convinced that one had been swallowed. He was unable by simple measures, such as the finger in the fauces and holding the child up by the heels, to give relief to the dyspnœa, and the child was then sent to the hospital.

When I saw him first, about two hours after the accident, there was such extreme respiratory distress that prompt relief was necessary. A careful search was made of the mouth and fauces with the finger, but without revealing the presence of a foreign body, and as the dyspnœa was too great to permit of a prolonged examination, I opened the trachea without giving an anæsthetic. As soon as this was done, and it was accomplished without difficulty and with really very little pain to the patient, the relief was instantaneous Nothing could be found in the trachea or bronchial tubes, and a silk catheter could be passed into the mouth from below.

I next passed a catheter down the œsophagus nearly to, but I regret to say not quite into the stomach, and also a pair of long-curved forceps, but without meeting with any obstruction or evidence of a foreign body.

A small silver tube was introduced into the wound in the trachea, and the child was put to bed in a room specially prepared for him.

He was quite comfortable for two days, and during this time Dr. D. Braden Kyle, laryngologist to the hospital, kindly examined the case with me, to determine whether a foreign body was still in the throat. He had the greatest difficulty in making an examination, and all that could be determined was the fact that the larynx was much congested, as though it had been injured.

At first the child was able to swallow fluids in small quantities with comparative ease, but during the time the tube was in place the difficulty in swallowing increased rapidly. He would take a drink of milk eagerly, hold it for a moment, and then allow it to run out of his mouth. I thought that as the child was very small, and the tube somewhat large for him, this was the cause of the trouble, and that the tube was pressing upon the œsophagus from in front. I therefore removed it, and gave the resident surgeon strict orders to replace the tube upon the first signs of returning dysponœa. All went well for about eight hours, when the difficulty in breathing recurred, and the tube was replaced without difficulty. Still the boy did not swallow nourishment as he should, and was losing strength rapidly in spite of rectal feeding.

I now determined to make another and even more careful search of the gullet, first, with my finger, and then with instruments. Upon pushing my finger far down the throat I was just able to feel a smooth, hard body, which proved to be the rounded point of an iron jackstone. By external palpation of the neck nothing could be felt that would lead to the supposition that a foreign body was present. After some little difficulty the jackstone was grasped in the jaws of a pair of curved forceps and removed. The care necessary to do this, on account of the large size and irregular shape of the jack, made it a tedious process. The utmost gentleness was exercised in these manipulations, but the mucous membrane was somewhat torn, for quite an amount of bloody mucus was brought up.

* Professor of Orthopedic Surgery in the Philadelphia Polyclinic, Attending Surgeon to St. Agnes' Hospital, Assistant Surgeon to the Orthopedic Hospital and Infirmary for Nervous Diseases.

The child died on April 8th from exhaustion, and as no post-mortem examination was permitted, the extent of the injuries done to the œsophagus and surrounding tissues can only be conjectured.

At the time of my first examination, just prior to the tracheotomy, I could not feel the jack with my finger passed well down the gullet, neither could I feel any obstruction to the passage of the forceps nor to the catheter, which I thought had passed into the stomach. Both must have passed below the point at which the jack was subsequently found.

The interference to the respiration was due entirely to the jackstone within the œsophagus which pressed upon the trachea, and not, as I had supposed before operating, to the jackstone within the trachea itself.

This case has been a severe lesson to me, and has taught me that in all cases of dyspnœa, supposed to be due to a foreign body within the trachea, a careful search of the gullet should first be made, and the probang should be passed into the stomach itself. Until this is done we must not open the trachea, provided this can be done without jeopardizing the life of the patient by too long and exhausting a search.

I can only explain the fact that I did not strike the jackstone with my forceps or with the catheter by the supposition that they passed between the prongs of the jack, and thus did not touch the substance of the iron, or else that it was so far down the gullet that I did not reach it in my search. I report this as a warning to others that such an accident may happen, even when it was thought that all danger of such an oversight had been provided against.

One reason why more stress was not placed upon the fact that no foreign body was discovered at the time of operation was the knowledge that no one saw him swallow the jack, and it was thought possible that it might have been coughed up, and dyspnœa be due to the violence done to the larynx in its passage in and out.

In looking over the literature of this subject I have found the following case reported by Dr. T. M. Markoe (*New York Med. Jour.*, May, 1886), which is very similar in many respects, and I quote it somewhat in detail:

A little girl, aged three years, put an iron jackstone into her mouth and swallowed it. Her mother could feel a hard body with her fingers pushed well down the throat, but a physician who saw her almost immediately could feel nothing. He passed a probang into the stomach, as he thought, but met with no obstruction. The child was first seen by Dr. Markoe four days after the accident, and during this time there had been some little cough, but no dyspnœa or evidence that the child felt local pain other than the fact that she would not swallow solid food, although fluids were taken without difficulty.

A careful examination while the child was under the influence of ether, with a lead probe, detected a foreign metalic substance after the probe had passed five inches down the œsophagus, but there was no evidence of its presence on external palpation of the neck.

Very gentle efforts were made to extract the foreign body with forceps, but without success, and mucus tinged with blood showed the tissues were being torn by the manipulations.

The next day further attempts at extraction were made, and also to push the jackstone into the stomach, but without success. Œsophagotomy was performed on the left side by Dr. Markoe, who found the œsophagus had been perforated, and the jackstone lying almost entirely without the tube, having perforated its wall from within outward.

Whether it had been pushed through the wall in the efforts to dislodge it with the probang or not, it was impossible to say, but it was due to some form of mechanical violence and not to ulceration. The child died of exhaustion twelve days afterward.

Hydrochlorate of Chalk for Pruritus Ani.

Take (*Sem. Med.*) a piece of cotton gauze two or three centimetres long, which has been moistened with a solution of hydrochlorate of chalk, two to the hundred. Push up the anus and leave in place until sharp smarting commences. Then remove it and wipe surface of anus dry. Itching immediately ceases. If it should return, employ the same proceeding. It appears that this solution simultaneously clears up all the eczematous patches about the anus and scrotum, a condition so generally concomitant with an anal itch.

EDITORIAL.

INEBRIETY—GOLD-CURED.

Some months ago, it will be remembered, THE REPORTER* noted with approval and quoted in full a plan proposed by the editor of the *Christian Advocate* for determining, at least approximately, the truth of claims made for and by the so called Keeley gold-cure of inebriety.

THE REPORTER commended this plan because of: 1, the unimpeachable character of the *Advocate*, and of its editor; 2, its abundant sources for reliable information; 3, the distinctly limited nature of the inquiry; 4, the simple and effective precautions to secure accurate testimony, personally vouched for by the witnesses; 5, the unbiased relation to the subject of the journal.

THE REPORTER regrets it can not reproduce the entire report as contained in the *Christian Advocate* for May 2d, inst., but enough is given to show the righteousness of the investigation; the care used to secure only truthful and pertinent information and, incidentally, to demonstrate that not the most skilled and cunning in the "monkey" business, can use the editor of the *Advocate* as cat's-paws to pull nuts out of a fire. None succeed; few try more than once.

We give an abstract of Dr. Buckley's editorial:

"In order that no part of the following article shall be misunderstood, special notice is given that the object of the editor in investigating the results of the Keeley method is not to prove the system worthless, or to deter drunkards hopeless of restoration by other means from trying it; but simply to ascertain whether the assertion of its inventor and his agents, that ninety-five per cent. of all cases treated are cured, is true."

The Keeley Company appears to us to have placed itself in a peculiar light. Its claims are that more than two hundred thousand persons in the United States have been graduated from Dwight and from the different institutions where the

* THE MEDICAL AND SURGICAL REPORTER, Vol. lxxi., No. 7; p. 217.

Keeley treatment is administered. The secretary of perhaps the most important Keeley Club in the United States writes us that among these two hundred thousand persons are sixteen thousand physicians. Dr. Keeley and all his agents, representatives and friends have been constantly declaring that ninety-five per cent. are permanently cured, and have sometimes gone so far as to say that five per cent. for relapses is a large allowance. Under such circumstances one might suppose that they would be utterly unconcerned and unmoved by an offer on the part of a respectable journal, having nearly fifty thousand subscribers, to receive and publish facts within their personal knowledge, guaranteed to it by ministers and physicians.

Since the company keeps its remedies a secret, no investigation could be made into the elements of which they are composed; but of the careers of persons who have taken the treatment, knowledge can be acquired. But immediately upon the first effort, so far as we know, to test their oft-repeated statements, they deliberately set to work, first to prove that physicians cannot be relied upon to state the simple facts that have come under their knowledge; and second, that of the clergy, "because of the great number who believe it is a sin akin to blasphemy to admit the efficacy of anything save God's grace as a cure for drunken humanity, we think such faith would debar many of them" from being impartial jurymen; and then to show that we in particular are prejudiced against the cure.

We think that when the methods of our investigation are described the reader will conclude that whatever prejudice we have cannot possibly have affected the result.

We have, and still have, a prejudice against Dr. Keeley regarding him as pursuing quackish methods and governed primarily by the desire to make as much money as he can, and believe that that is the chief reason of the keeping of his remedies secret. Having been interested for many years in the reformation of drunkards, we have been in the habit of preserving everything related to the subject.

About thirteen years ago Dr. Keeley sent us a circular, offering for nine dollars to cure drunkenness by two bottles of medicine.

In addition he says: "All medicine packed securely *and sent masked* when so desired."

In the further description of it he testifies: "Up to this time I have not heard of a single instance of failure."

He had then been sending these medicines around the country long enough to make a call for a third edition of this circular; he claimed then to have been using the remedy five years. This is followed by a number of certificates in the usual patent medicine style.

He further says: "I have the fullest confidence in its merits, and feel no hesitation in guaranteeing it to be what the press has already named it, 'An infallible cure for drunkenness.'" He observes, however, that "there may be some cases of failure in the future."

As he signed himself "Surgeon of the Chicago and Alton Railroad and Late Surgeon U.S.A." while resorting to these quackish methods, we wondered whether the phrase "Surgeon C. & A. R. R." signified that he was the general surgeon of that corporation, or whether "Late Surgeon U.S.A." meant that he ever was a surgeon in the regular army, and were informed that, like many other physicians along the line of a railroad, he was employed in case anything happened at the little village where he lived, and that he had been a surgeon in the late war in connection with a volunteer regiment.

We suppose that these special titles were added simply to push his "*infallible* cure" in "two bottles at nine dollars,"

and frankly confess that such a circular with such statements and signatures, created a prejudice in our mind, especially as he repeatedly declared that "the double chloride of gold in my hands has uniformly effected a cure in nine days, and left the patients without a desire for intoxicants or for any stimulant as a substitute, no patient so cured having relapsed into the drinking habit;" and published extracts of letters to himself calling his two bottles "the *saviour* and *redeemer* [italics not ours] of the drunkard's mind and body; because it *saves* him from temptation and *redeems* him from the effects of a dissipated life."

This prejudice did not, however, lead us to conclude that the contents of the bottles might not be valuable, but simply that the inventor had in view the making of money, and therefore was willing to turn aside from the regular profession of medicine and patent his bottles "*in order to protect himself more fully.*" This he had a right to do, but not as a regular practitioner of medicine.

We were the more ready to conceive a prejudice from this cause, that in 1880 he had sent us a circular advertising a medicine which he declared to be an infallible and certain remedy for another disease. This he professes to cure by two bottles which have a thoroughly quackish name, and are sold at five dollars a pair. In the circular is an address to those afflicted, assuring them that if they would buy these bottles and take the medicine they would not need a vacation to recuperate their wasted energies, but could go on with the arduous work of the pulpit and parish, the practice of law, mercantile pursuits, journalism, and politics (it being especially useful to politicians in a campaign, during which "an immense amount of cerebral force is expended"); in fact, the contents of these bottles would "be found more beneficial than three months in the White Mountains or a summer at the seaside."

Considering that for five years he "never knew a failure" of the bottles at nine dollars a pair to effect a permanent cure of drunkenness—"in nine days"—while requiring no one to leave his home or his business, or putting him to any other expense than the purchase of the medicine, and that the other medicine, with its two bottles at five dollars a pair, never failed to cure a terrible disease which Dr. Keeley says "often leads to insanity, epilepsy, paralysis, and dipsomania," we confess that our prejudice increased when we saw him withdrawing from the market the bottles for the cure of drunkenness, and raising the price to twenty-five dollars a week, and requiring three or four weeks' treatment at Dwight, and selling State rights throughout the country at about the rate of $23,000 for a State of moderate population, largely rural; furnishing all the medicine, and getting forty per cent. on all used by each institute, each patient requiring five bottles, at four dollars and fifty cents each, as we are informed by an admirer of the system.

Nor can we say our prejudice was diminished on finding the Keeley Institute of Maine sending to the physicians of that State a typewritten circular, signed by the "president," of which the following is the first paragraph:

"In realization of your high professional as well as social standing in your community, and the amount of force your words would bring to bear upon the unfortunate subjects for whom this treatment is calculated, I have determined, in order that such subjects who require but a word of encouragement from their physician to place them in an institution where they can be lifted from the dreadful bondage which surrounds them and makes their lives a burden, not only to themselves, but their families as well, to give a commission of $15 for every patient (male or female) brought to this Institute for treatment."

Neither was our prejudice favorably af-

fected by finding that whenever a person relapses the plan is to denounce him as an idiot, or demented, or accuse him of not having wished to be cured.

Nor was it removed by the seemingly plausible proposition to allow us to bring drunkards to Dwight to have them treated in order that we might report the effects.

We consider that proposition intended to deter us from making the investigation, or in case of our refusal to put us in the position of refusing what would seem to be a genuine offer.

We do not accept it, because, among other reasons, we do not happen to have on hand a number of drunkards "numerous enough to index general results." And if we had, we could not take them to Dwight, "go with them ourselves, visit every treatment for twenty-eight days, mingle freely with the long line of patients in attendance there, take them home with us, and watch their progress toward a life of sobriety for days, weeks, months, and years."

If the Keeley Cure was just being launched upon the country, it might be reasonable to say to a respectable journal whom the proprietor had interested in his remedy, "Bring on your patients; we will charge you nothing for medicine or treatment, and you can see the effect;" but even then the company agreeing to the terms of this proposition would have to wait some "months or years" before a testimonial would be valuable.

But the Keeley Company claims to have sent out more than two hundred thousand cured men into all parts of the United States.

In our personal acquaintance of those who have taken the Keely cure—not one of whom was demented or did not wish to reform—a little over fifty per cent. have relapsed. The ministers and physicians who have responded to our inquiry have their list of personal acquaintances, and they can tell us what they know.

What is the bearing of the prejudice which we admit, and the growth of which is explained by the preceding facts, on this investigation? Simply this: that, believing Dr. Keeley to be controlled by his pecuniary interests, and of such a temperament as to be capable of making statements with regard to his remedies, as to cures and relapses, similar to those put forth by most other patent medicine venders, we do not place implicit confidence in them nor in the repetition of them by the persons pecuniarily interested in the cure, or by those who derive their information from such persons.

Therefore we endeavored to get information where the persons sending it could not be influenced by pecuniary interests or by an exaggerated condition of mind.

Nevertheless, recognizing the fact that a person prejudiced against the reliability of statistics published by Dr. Keeley, his colleagues and employees, should not be trusted with the tabulation of the returns, immediately after making our first call for facts we instructed the office editor who opens the mail to take entire charge of the correspondence, not exhibiting to us or communicating the contents of any of the letters containing the figures.

Shortly before the date fixed for the closing of the investigation we instructed the said office editor to place in the hands of the editor of one of the subordinate departments of the paper all correspondence relating to the matter, to prepare the same for tabulation.

Finally, we secured two gentlemen, neither of whom is a physician or a minister—one a merchant of long and honorable standing in this city, the other on the editorial staff of the *Popular Science Monthly*, to be present at the tabulation, to examine the documents and to decide in doubtful cases whether statistics should or should not be admitted into the table.

TABULATION OF RESULTS.

Letter No.	Cases.	Held.	Relapsed.	REMARKS.
1..	10	2	8	
2..	3	0	3	
3..	6	5	1	
4..	17	0	15..	One became insane; one died while drunk within six months.
5..	4	1	3	
6..	3	1	1..	One uncertain,
7..	3	1	2..	These two kept sober over two years.
8..	8	8	0	
9..	4	3	1	
10 .	1	0	1..	Relapsed after thirteen months.
11..	3	1	2..	One took cure five times.
12..	5	2	3..	Two took treatment twice.
13..	1	1	0..	
14..	8	0	8..	Two afterward reclaimed by church; five remained sober more than nine months.
15..	1	0	1	
16..	1	1	0	
17..	8	0	8..	Two died; one is insane.
18..	4	3	1	
19..	1	0	1..	Took treatment twice.
20..	4	3	1	
21..	2	0	2..	One committed suicide.
22..	2	0	2	
23..	3	2	1	
24..	8	4	4..	One took cure twice.
25..	10	5	5..	
26..	1	0	1..	Remained sober one year.

62..	29	7	22..	
63..	5	5	0..	
64..	3	1	2..	One remained sober eleven months one died after drinking.
65..	21	16	5....	Two remained sober one year.
66..	2	0	2	
67..	4	1	3....	One died with delirium tremens.
68..	2	1	1	
69..	2	2	0	
70..	3	0	2....	One died under treatment.
71..	10	1	9 ..	One died with brain trouble; two insane.
72..	6	1	5....	Two treated twice.
73..	10	10	0	
74..	8	1	7....	Two mental and physical wrecks.
75..	10	10	0	
76..	20	19	1	
77..	3	1	1....	One insane.
78..	1	0	1....	Committed suicide.
79..	3	0	3..	One insane and died with delirium tremens.
80..	4	0	4	
81..	2	1	1	
82..	1	0	1	
83..	3	3	0	
84..	5	0	4....	One died insane.
85..	4	2	2	
86..	33	1	32....	One insane.
87..	10	0	10	
88..	3	2	0....	One died in three days insane.
89..	10	8	2	
90..	3	3	0	
91..	2	1	1	
92..	6	0	6....	One took it three times.
	534	275	251..	Thirteen insane; eleven died; two committed suicide; fifty-one and one half per cent. cured.

The letters containing tabulated statistics came from twenty-seven States and Canada.

The communications were ninety-two in number, representing *sixty-eight* clergymen and *twenty-five* physicians. (The statistics given in one letter were certified to by both a minister and a physician.) In no instance did any two letters included in the table come from the same place.

All these persons are subscribers, most of them of long standing, and their correspondence shows that they rigorously excluded all cases of which they had not accurate personal knowledge. The statement in the hostile circular previously quoted, that the number of returns from physicians would be largely in excess of those from ministers, is shown by the returns to be very wide of the mark.

We repeat, in concluding this statement, that our object has *not* been and *is* not to deter drunkards from trying this or any other cure, but to ascertain whether the prospect of being cured is so great as to *warrant men in drinking, under the belief that ninety-five* per cent. of all drunkards can be cured.

We did not believe that to be true, and the facts herewith attested proved conclusively that it is not true, especially as many of the correspondents have shown themselves to be enthusiastically in favor of the cure, and very few have exhibited any prejudice against it.

ABSTRACTS.

PHYSIOLOGICAL PROCESSES AMONG THE POETS.

Some years since, David Barker, a distinguished poet, after the birth of his first child, wrote and published the pretty poem:

"One night as old St. Peter slept,
"He left the door of Heaven ajar,
"When through a little angel crept,
"And came down with a falling star."

"One summer, as the blessed beams
"Of morn approached, my blushing bride
'Awakened from some pleasing dreams,
'"And found that angel by her side."

"God grant but this—I ask no more—
"That when he leaves this world of pain,
"He'll wing his way to that bright shore,
"And find the road to Heaven again."

John G. Saxe, deeming that injustice had been done St. Peter, wrote the following as St. Peter's reply:

"Full eighteen hundred years or more
"I've kept my gates securely fast;
"There has no 'little angel' strayed
"Nor recreant through the portal passed."

"I did not sleep as you supposed,
"Nor left the door of Heaven ajar;
"Nor has a 'little angel' left
"And gone down with a falling star."

"Now ask that blushing bride and see
"If she don't frankly own, and say,
"That when she found that little babe
"She found it in the good old way!"

"God grant but this—I ask no more—
"That should your number still enlarge,
"You will not do as done before,
"And lay it to old Peter's charge."

To settle the dispute, Judge J. W. Starr wrote the following:

"I read of David Barker's babe,
"And Heaven's door ajar,
"And how it came from glory land
"Down with a falling star."

"'Tis said St. Peter gave the babe;
"Saxe doubts the bold assertion,
"And calls upon the blushing bride,
"To make a different version."

"Twixt David Barker and his bride
"This is a sacred cause;
"They know just how the baby came;
"It came by natural laws."

"Saxe writes of lovely summer morn;
"He writes of other things;
"He writes about the good old way
"New life within him springs."

"God grant but this—I ask no more—
"May father, son and bride
"Join St. Peter in the end,
"And John G. Saxe beside."

—*N. C. Med. Jour.*

The Treatment of Influenza.

Sodium benzoate, given in solution, the dose being ten to twenty grains every two to four hours, is one of the best of remedies in cases in which there is much pain in the back, sore throat or tendency to suppression of urine.

Strychnin arsenate or strychnin sulphate, one-half milligram(1/120 grain) every hour or two, not more than eight or ten doses being given daily, admirably supports the nervous system; and therefore the heart. When rheumatoid symptoms exist, the sodium benzoate may be substituted, supplemented or followed, by cinchonidin salicylate, five grains every fourth hour, or until there is ringing in the ears. Rest in bed, warmth, ventilation, simple, easily-digested, nourishing food, plenty of pure water, are all important. Febrile temperature does not, as a rule, call for special interference. The coal-tar antipyretics are not needed and are dangerous.

SOMATOSE—A CONCENTRATED NUTRIENT.

The considerations which chiefly influence the physician in the selection of a food preparation for the sick are, whether it is nutitious in the true sense of the word, containing in small bulk a large amount of available nutriment; whether it is digestible without taxing the gastro-intestinal tract; whether it is promptly absorbed and assimilated; and, finally, whether it is palatable and suitable for prolonged administration.

Careful and extensive experiments seem to have shown that Somatose is eminently adapted for the nutrition of persons suffering from debilitating diseases of acute or chronic character—such as typhoid fever, pneumonia, phthisis, gastric affections—and for the alimentation of weakly children and convalescents. It consists almost entirely of the albumoses or active nutrient constituents of meat, and is digestible, is rapidly assimilated and is relished even by the most fastidious. In view of the large amount of condensed and available nutriment it contains, Somatose is cheaper than other nitrogenous food products—a fact which deserves careful consideration.

Among others, Dr. Weber, of Strassburg (*Berlin, Klin. Wochenschr.*, No. 9, 1895), has recently contributed the results of his experience with Somatose. It appeared to him of especial value in cases of gastric catarrh, ulcer, cancer, etc., when it was desirable to subject the hyper-sensitive mucous membrane of the stomach to as little exertion as possible. He reports a case of gastric ulcer in which, in consequence of the pain produced by solid food, the patient had to be fed with soups and had become greatly reduced in flesh and strength. Somatose was administered in teaspoonful doses several times daily, and notwithstanding the occurrence of a hemorrhage he increased visibly in strength, regained his appetite, and soon was able to resume other light foods. This rapid improvement is ascribed by the author in great part to Somatose.

Infants suffering from gastro-intestinal affections also derived much benefit from the preparation. In cases in which milk was vomited, thin oatmeal gruel with the addition of Somatose, proved an excellent substitute, 1.5 to 3.0 grams being added so a bottle containing 240.0 grams.

Admirable results were also obtained in several cases of severe migraine attended with vomiting. A lady, thirty-five years old, suffered from such attacks, which lasted five or six days, regularly at the nenstrual periods, and as she was unable to take food during their occurrence, her nutrition had become impaired. Somatose, one teaspoonful in a cupful of light black coffee was, however, well tolerated, and was given several times daily. Since the time of its administration the patient experienced much less exhaustion after the attacks, looked better and increased 1½ Kilos in weight.

Weber is convinced of the utility of Somatose in all forms of anæmia both in the anæmic conditions of childhood which are associated with scrofula and rickets, and in the anæmia following the loss of blood or occurring during convalescence from febrile diseases. The conjoint administration of ferruginous preparations and Somatose, in all these cases, produced much better results than the use of iron alone. In convalescence it acted as a nutrient and stimulated the appetite. The author emphasizes the fact, in view of the small quantities required, Somatose is not an expensive preparation as compared with other food products, which even in much larger doses furnish less nutriment to the system.

For the Relief of Painful Swallowing in Phthisical Patients.

Lermoyez (*Journal des Praticiens*) recommends insufflations of the following powder instead of painting with cocaine:

Morphii hydrochlor.....	aa gr. xx
Sacchari lact.....	
Gummi arab.....	gr. xv. M
Fiant pulv	no. lx

Of this powder only about one-half grain should be used at each insufflation.

The application should be made before meals especially, and the effect lasts for many hours.—*Therap. Monathschr.*

OBSERVATIONS ON THE TREATMENT OF FIBROIDS OF THE UTERUS.

Dr. O. S. Phelps, of Now York (*Am. Medico-Surg. Bull.*), reports an unusually complicated case of uterine fibroid in a girl seventeen years of age, who came under his care in July, 1894. She was sent from the West to New York by the family physician to have a hysterectomy performed, and came directly to his sanitarium. The tumor was 8 to 10 centimeters in diameter, and crowded the uterus well over to the left side. The uterine cavity measured five inches and the organ with its appendages was surrounded and bound down by an inflammatory exudate. The bladder was impigned upon so that it could not hold more than one or two ounces of urine, causing the patient great agony to evacuate it. The whole mass, including the tumor, exudate, uterus and appendages, filled the pelvis and rose well up to the umbilicus. The patient was much emaciated, weighed 60 pounds (normal weight, 125 pounds), could not stand or walk, nor could she turn in bed without great pain. Temperature 100° to 103°. Dr. A. H. Goelet was called in consultation and confirmed the diagnosis; he also agreed that no operation could be considered at that time, but thought ligation of the uterine arteries might be resorted to later. The treatment adopted was the high tension faradic current, fifteen minutes thrice daily, vagino-sacral and abdominal. At each seance the temperature was reduced one-half to one degree, lasting one to two hours. A system of feeding was adopted under the guidance of microscopical observations of the blood and secretions to determine the correct choice of foods. In two months the temperature remained normal and the weight had increased 30 pounds. Galvanism was then used with anode to tumor per vaginam by means of a special clay electrode with cathode closely adapted to tumor over abdomen; 20 to 30 milliamperes of current, 7 to 10 minutes, every five days. January 15 tumor was reduced to a mere nodule, about the size of a walnut, exudation gone; uterine cavity measured 2¾ inches. Patient's weight was then 125 pounds.

Conclusions.—The writer ascribes the favorable results in this case—

First. To a systematic plan for restoring the nutrition under such unfavorable conditions as are afforded a sanitarium.

Second. To the persistent use of the high tension faradic current all to allay pain, reduce inflammation and induce absorption.

Third. To the galvanic current, so applied as to concentrate its action upon the fibroid growth.

Losophon a Dermal Antiseptic.

In that large class of cutaneous affections due to bacterial infection, Losophon has been found to occupy a distinct field of therapeutic utility. It is a well recognized fact that these affections present frequently great obstacles in the way of treatment because the microbe penetrates so deeply the epidermis, that it is not readily dislodged.

It is therefore of great importance to first secure a clean field upon which the antiseptic can exert its action. In parasitic diseases of the hairy parts of the body, thorough epilation sometimes is of utmost importance as a preliminary to the use of germicides. After thorough epilation the integument should be thoroughly cleansed with soap and water and dried before application of the antiseptic, and it will sometimes be found of advantage if the parts are very oily, to sponge them with ether or benzine. Iodine and iodine derivatives have long been favorite applications in the treatment of such parasitic affections of the skin as ringworm, and pityriasis versicolor. Losophon, containing as it does about 80 per cent. of iodine, in combination with cresol, an excellent antiseptic, has been found one of our best remedies in this class of cases. It not only promptly destroys the parasite, but alleviates the itching and reduces the inflammation. To obtain the best results, it is not enough to simply mix it with fats, but it should be thoroughly dissolved in oil, before being added to the ointment base. Preparations up to 5 per cent. are usually sufficient, although occasionally stronger ointments may be required.

SOCIETY REPORTS.

PHILADELPHIA ACADEMY OF SURGERY.

March 4, 1895.

Dr. W. J. Taylor reported a case of

A JACKSTONE IN THE ŒSOPHAGUS, WHICH PRESSED UPON THE TRACHEA AND PRODUCED SUCH RESPIRATORY DISTRESS THAT TRACHEOTOMY WAS NECESSARY.

[See page 664.]

DISCUSSION.

DR. JOHN B. DEAVER: I have recently operated upon a lady who swallowed a fish bone, which lodged temporarily in the œsophagus; but which, however, could not be found. Her physician, Dr. J. B. Walker, upon the day following the accident, finding an emphysematous condition of the neck, asked me to see the patient with him. Upon examination I found not only emphysema, but also some fluid deep in the tissue of the neck. The effusion did not connect with the trachea. I cut down upon the swelling, evacuating a small amount of very fetid pus. At the bottom of the wound, located behind the lateral lobe of the thyroid gland, was seen some slough and an opening which communicated with the œsophagus. The bone was not found. The wound was packed lightly with iodoform gauze. Owing to the age of the patient, the difficulty in feeding her, and the extensive sloughing, death occurred within a week following the opening made in the neck.

DR. J. M. BARTON: Some years ago I saw a case over in Camden of a child who had a jackstone in its throat similar to the case reported to-night. The size of the jackstone precluded the idea of its being in the larynx, although there was impairment of voice. The foreign body was discovered pressing against the back part of the œsophagus, where it caused ulceration, from which the child ultimately perished.

DR. DEAVER: I have seen ulceration of the larynx result from the pressure of a foreign body in the œsophagus.

Some years ago I performed œsophagotomy for the removal of a partial plate of artificial teeth which had occupied the œsophagus for seven days. Death resulted from sepsis. Post-mortem showed ulcerative communication between the œsophagus and the larynx.

DR. R. H. HARTE: At St. Mary's Hospital I saw a man, who in a fit of depression had wounded his throat and œsophagus with a razor, and in addition had plunged a red-hot iron into his right side and penetrated the liver. When he attempted to swallow liquids they regurgitated through the wound in the neck. The physicians present suggested œsophagotomy, and I recommended the passing of a tube down the œsophagus into the stomach through which he could be fed. This was done, and the patient recovered.

DR. WM. H. KEEN: I can recall a number of cases of asserted swallowing of foreign bodies, especially fish-bones. The great difficulty in these cases is in determining whether the foreign body is really there. In the cases reported very careful examination failed to detect the presence of the jackstone. I would ask Dr. Taylor if any attempt was made to relieve the patient by feeding him with potatoes, to facilitate the passage of the jackstone. A few days ago I saw a physician who in swallowing a piece of toast, coughed a piece of the crust into his naso-pharynx. Acute pharyngitis followed, which extended up the tubes and caused mastoid disease. An abscess formed which burrowed to the pharyngeal wall. I operated upon him and chiseled away most of the mastoid. I mention this to show how much injury may be done by such a simple body. The man was in good health at the time it occurred.

DR. TAYLOR: Dr. Keen speaks of feeding the child upon potatoes. The difficulty was, that when I saw the child the respiratory distress was so great that I am very sure that unless tracheotomy had

been done at once the child would not have lived more than a few hours. Moreover I had very little idea that there was a foreign body in the œsophagus at all, as I attributed the difficulty in swallowing to the pressure of the tracheotomy tube.

Dr. John B. Deaver read a paper on

THE USE OF MALGAIGNE'S HOOKS FOR FRACTURED PATELLA.

I present these two cases of fracture of the patella as showing the result obtained by the use of Malgaigne's hooks. The hooks were introduced the same day in each case, one week following the fracture. Here, as is my usual practice, the hooks were introduced under aseptic precautions and with the patient anæsthetized. It is now six weeks since the introduction of the hooks, and I think the Fellows will agree with me that the result in each case is most satisfactory.

The degree of flexion and extension is almost normal. The apposition of the fragments is perfect. You will please understand that I have made no claim for bony union, as I believe that this can be obtained only by opening the joint and wiring. The Barker operation, that of subcutaneous ligation, offers no advantage over the use of Malgaigne's hooks, the result obtained in both instances being practically the same, the risk being increased by the ligature method.

DISCUSSION.

Dr. R. H. Harte: I think that Dr. Deaver's testimony with regard to Malgaigne's hooks agrees with the testimony of most experienced surgeons. They have been objected to by persons who have never tried them. Their results are much more satisfactory than those from the starch bandage, recommended by Agnew. I regard them as a very satisfactory method of treatment.

Dr. J. M. Barton: I would like very much to see a series of fractures of the patella about one or two years after the injury. It is very common immediately after any method of treatment to see close approximation, but in time they usually stretch some inches apart. It would be of great importance to determine if exposure of the patella by incision, removal of the interposed torn edges of the capsule and wiring of the patella will not give better results than the use of Malgaigne's hooks. It is certainly quite unfair to the patient to expose him to the risks of the graver operation if the milder will give equally good results.

But the exhibition of patients immediately after getting out of bed proves nothing. If the fractured ends of the patella are equally close one or two years later the efficiency of the treatment will be fully proved.

Dr. J. Ewing Mears: The subject of fracture of the patella is an old one in this academy. It has been discussed here quite often, and a number of cases have been presented. At the time of the last presentation of cases I took occasion to say I thought the time had come to make a reform in our nomenclature. I think the fracture of the patella is not the injury we are called upon to treat; but a rupture of a ligament—the patella being only a sesamoid bone developed in the tendon of the quadriceps muscle, and fractures of this bone are incidental to ruptures of this ligament. When this is the result of force applied directly there is little or no separation of the fragments. But in the cases caused by muscular contraction the ligament is much torn and the fragments are widely separated. This difference in the degree of separation of the fragments under the two causes, I think, proves conclusively that the ruptured ligament is the lesion present demanding treatment, and not the fractural sesamoid bones.

Whatever the plan of treatment adopted, I believe it should have for its object the union of the ruptured fibres in the ligament as firmly as possible. I have kept patients in bed for three months in order to make these adhesions very firm. If the fibres of the ligament are greatly lacerated and stretched it will be necessary to cut down and remove the portions of the torn ligament and approximate the ends by suture. In cases of direct force the ligament is not torn, separation of the fragments of the bone does not occur to any extent, and treatment is very much shortened.

Dr. John B. Deaver presented a case from which he had removed

A TUMOR INVOLVING THE UPPER CERVICAL CORD OF THE BRACHIAL PLEXUS.

B. A., aged forty years, married, was operated upon for tumor of the neck January 17, 1895.

Diagnosis, neuroma. A careful dissection, exposing all the tissues of the neck in relation with the three cervical cords of the brachial plexus, demonstrated the presence of an oblong tumor, smooth in contour, involving the upper of the three cords. The growth was so intimately associated with the nerve-trunk in question that it was necessary to divide the cord on either side to effect its removal. Strange to say, paralysis did not follow the division of the cord; there was but slight motor disturbance.

DISCUSSION.

DR. DEAVER: Some of the gentlemen present seem to doubt the case was really what I claim it to be.

I flatter myself that I am sufficiently familiar with the topography of the neck to recognize the cord of the plexus. There was no doubt that the tumor, which when examined proved to be a neuroma, was so intimately connected with the upper cervical cord that to remove it required section of the cord above and below the growth.

An attempt was made to splice the divided ends of the nerve, but it could not be done. They were connected, however, with several strands of catgut.

The apparently puzzling part of this case is the absence of paralysis following removal of the tumor.

When we consider that this growth first showed itself seven years ago, and that it has been as large as at the time of its removal for some months, and that it involved the entire upper cervical cord of the plexus, as proven by examination of the specimen, would we expect paralysis to follow the removal of that which had already destroyed the conducting power of the affected cord?

DR. KEEN: With regard to the brachial plexus, I am willing to take Dr. Deaver's word that it was the brachial plexus nerve tubules which were identified. I should like, however, to see the specimen. But it is very remarkable that we can cut away a growth dividing the cord without having paralysis. I should like to know if the tumor is sessile upon the nerve, or the nerve was diffused and a part of the tumor. It is incomprehensible to me that there should be compensation in the case. As I understand, there are no motor symptoms whatever.

DR. MORTON: Did the nerve present any evidence of degeneration, or was there anything to account for the formation of the tumor?

DR. DEAVER: In answer to Dr. Keen, I would refer him to the anatomical construction of the brachial plexus.

In answer to Dr. Morton, I would state that the history of the case does not offer any explanation as to its causation.

Dr. Deaver presented a case illustrating a very marked form of congenitally contracted bladder. The trouble, that of frequent micturition, dates back to three years of age. The capacity of bladder when he came under my notice was about one and one-half ounces. Examination of the urethra with urethroscope and of bladder with cystoscope negative other than demonstrating the small size of the bladder. Perineal cystotomy gave relief while drainage-tube was *in situ* and for two months after the wound had healed, he now returns six months since the operation with the symptoms quite as bad as when I saw him for the first time.

DR. GEORGE E. SHOEMAKER: Has an attempt at persistent dilatation of the bladder been made?

DR. KEEN: Would the H. Marion Sims operation be of use?

DR. JOHN B. ROBERTS: Might not this be a case of chronic tuberculosis of the mucous membrane of the bladder? I did a supra-pubic operation some years ago for what I think was tuberculosis of the bladder, leaving the wound open and washing it out with boric acid. A fistule remained a long time, and the washing caused a small calculus in the bladder. This was passed by the urethra after dilatation with bougies. I dilated the sinus and curetted it, and then lost sight of the patient. In this case the bladder wall was very contracted, and I had great difficulty in finding and opening the small bladder.

DR. KEEN: In order to make such a method of treatment effective it should be done when there was no drainage-tube in the bladder. I should advise a trial of systematic dilatation of the bladder as recommended by Sims. I think that the water should be left in. Otherwise, the only treatment would be a palliative one by wearing a urinal.

MR. PRESIDENT AND FELLOWS: I am prompted first to report the following case from the fact that it is one of the youngest patients from which so large and solid a malignant growth of the ovary has been removed successfully. In going over the literature of the history of abdominal section in children for the removal of ovarian tumors I find this to be the youngest patient from which so large a sarcoma of the ovary has been removed, and further that nearly all of the operations which have been done were for ovarian cyst or dermoid.

In the case I report there was neither precocious menstruation nor evidence of premature sexual development.

In an article by J. Halliday Croom, *Edinburgh Medical Journal*, vol. xxxviii, there is a tabulated report of the cases operated upon up to 1893, gathered from the available literature. These cases are recorded under the following heads, viz.:

1. Precocious menstruation, with an early appearance of the external manifestations of puberty.
2. Sexual development without menstruation.
3. Menstruation previous to development of the sexual organs.
4. Early conception and pregnancy.
5. Premature sexual development, associated with tumors of the generative organs.

On December 20, 1894, I was asked by Dr. W. O. Higgate, of West Philadelphia, to see the patient in question, M. B., aged six years, white, female.

Dr. Higgate first saw the patient on the evening of December 18th for a pain in the stomach, so described by the mother. Upon palpating the abdomen Dr. H. discovered an abdominal tumor. There is no history prior to this date, excepting that three months previous the child complained of a pain in the side, which lasted for a few hours, and was relieved by home remedies. She was going to school up to and including the date when first seen. The pain she was suffering from on December 18th was due to suppression of urine; one ounce of urine was secreted in the succeeding twenty-four hours; this was drawn by catheter. After this the amount gradually increased for a week, when it reached the normal amount. At my visit the child was anæsthetized, and the examination showed plainly the presence of a large solid tumor occupying the pelvic and lower half of the abdominal cavities. Examination per rectum gave the impression that the growth was ovarian. December 22d Dr. John Ashhurst, Jr., saw the case with Dr. Higgate, and examined the child under ether. The diagnosis of ovarian growth was concurred in.

Operation, December 27th. The points of interest in connection with the operation were the ensiform adhesions of the great omentum, the transverse colon, and the sigmoid flexure of the colon. Numerous ligatures were required in separation of the adhesions. The growth was delivered with difficulty; there was free bleeding from the floor of the pelvis, which was, however, promptly controlled by ligature. During the necessary manipulation the field of operation was walled off with gauze, which facilitated the rapidity of the procedure and further lessened the degree of shock. The pelvis was dried with gauze, and glass drainage introduced. Wound closed and dressed aseptically. Recovery uninterrupted.

DR. H. R. WHARTON reported a case of

EXCISION OF ELBOW-JOINT FOR FRACTURE OF CONDYLE OF HUMERUS, WITH POSTERIOR DISLOCATION OF THE BONES OF THE FOREARM.

Mrs. W., aged thirty-five, received a fall April 29, 1894, sustaining an injury of the right elbow, which was diagnosed as a dislocation with fracture of the condyles of the humerus. She was sent to me in October, 1894, and upon examination of the arm I found marked deformity in the region of the internal condyle of the humerus and a posterior dislocation of both bones of the forearm, the arm being rigidly fixed at a right angle, and the patient complained of constant pain in the elbow.

I advised excision of the elbow-joint as the operation most likely to give her a useful arm.

On November 8, 1894, I excised the right elbow-joint, finding that there had been a fracture involving the internal condyle of the humerus, and that the ulna and radius were dislocated backward, a large amount of callus had been thrown out, which made the operation a difficult and tedious one.

The patient did well after the operation; the wound healed promptly, and at the end of four weeks the patient had a fair range of motion in the new joint. You will notice on examining the arm that the patient has remarkably free flexion and extension of the arm, also good supination and pronation, and as the result of operation has attained a very useful arm.

ALSO A CASE OF LOOSE CARTILAGE IN KNEE-JOINT.

J. W., aged twenty-four, was sent to me with the history, that for some years he had suffered from a movable body in the left knee-joint which at times interfered with the motion of the joint.

He stated that four years ago he had wrenched his left knee by stepping upon a stone which rolled under his foot, and that after the accident the knee was bent and could not be straightened. This condition existed for four months; at the end of this time he regained use of the knee-joint, but noticed the presence of a body which moved about in motions of the joint, and at times entirely disappeared. At times its presence caused him more or less disability.

I had no difficulty in locating the position of the body, and after finding it, cut down upon it and removed it. I show the body removed, which is quite a large-sized one.

This case is of interest in that it points to the possible traumatic origin of some cases of loose cartilages in the joints. They are usually supposed to originate from the villous fringes of the sigmoid membrane; but some authorities, such as Paget and Teale, have contended that they might originate from detached portions of the articular cartilage of the joints.

DR. JAMES M. BARTON, recited some

UNUSUAL SYMPTOMS ACCOMPANYING A SMALL OVARIAN CYST.

I present this evening this small ovarian cyst, as it produced a very unusual train of symptoms. I removed it yesterday from a private patient, and present it now before decay or any attempt at preservation destroys any peculiarities it may possess.

Miss L. J., a patient of Dr. William L. Newell, of Millville, N. J., aged twenty years, and weighing 257 pounds, was taken ill with vomiting and purging October 14, 1894. Previous to that date she was in perfect health, but during the five months since that date she has been seriously ill. She has had a very heavily coated tongue, a foul breath and constant nausea. Her temperature varied from 99° to 100°, and occasionally rose to 101° and 102°. She has lost just exactly fifty pounds in weight. There was great pain and marked tenderness in the right iliac fossa. She kept the right leg constantly flexed. She could straighten it, but, as it greatly increased the pain in the right iliac fossa, she would soon again flex it. The loss of appetite was so marked that frequently for several days in succession she took no food whatever. During a period of ten days in November she and her mother both assure me she did not take a mouthful of food. Since then there were two other periods of eight days each in which she also took no food whatever. Some days she even took no water. She slept but little, owing to the constant pain.

The large amount of fat on the abdominal walls prevented anything being felt through them, though the patient complained greatly of tenderness when pressure was made in the right iliac fossa.

On vaginal examination a fluctuating, sensitive tumor was found low down in the right iliac fossa. It was some inches from the uterus, and, apparently not connected with it.

On different vaginal examinations made during the last few weeks the tumor occupied different positions; usually it was found low down in the right iliac fossa, twice it was in the median line, once to the left of the median line, and twice it could not be felt at all through the vagina. The maximum tenderness was always over the tumor when it could be found.

The patient was regular in her menstruation, her periods occuring every twenty-one days. Her bowels were slightly constipated but were otherwise normal.

At the operation, March 3, 1895, I found the growth to be a kidney-shaped multilocular cyst of the right ovary, a little larger than an adult fist. There were two points of strong omental adhesion, and the pedicle was nearly four inches in length.

The parietal peritoneum at the lower part of my incision, which was a median one, was greatly thickened, though not roughened or discolored. There were a few ounces of fluid in the peritoneal cavity. The appendix and its surroundings appeared to be in a normal condition.

There was no twist of the pedicle, and the strong omental adhesions, which evidently had existed for some time, would have prevented any great rotation of the tumor and pedicle.

March 28, 1895. The above described case has made an uninterrupted and complete recovery, and is now sitting up daily for some hours. All of her symptoms have left. Her appetite is good, there is no nausea, she sleeps well, and there is no tenderness in any portion of the abdomen. She is able to extend the leg fully and keep it extended indefinitely without discomfort.

Dr. R. H. Harte exhibited a patient, remarking: This man came to the Pennsylvania Hospital in December, 1893, with a small growth at the inner canthus of the eye. Dr. Harlan then removed a small portion, including the duct. In March, 1894, a section was removed and pronounced epithelioma. In June the growth was again removed. In November Dr. Packard removed a portion of the growth. When I took charge of the ward, five weeks ago, I found a rather ulcerated mass corresponding with the malar eminence, which was discharging pus. I advised removal of the superior maxillary bone, which I did. I removed the outer wall of the antrum and scraped the inner wall. I had to take a flap from the side of the face and also a flap from the forehead. He made a good recovery, returned to work on a farm, and has gained twelve pounds in weight. An interesting question is, what was the nature of the case? Although the microscopic examination pronounced it a case of epithelioma, I am inclined to think it was a case of rodent ulcer; this view being favored by the fact that there was no glandular infiltration.

Treatment of Vomiting and Gastric Irritation

Dr C. H. Miles recommends (*Clin. Jour.*) the following:

Creasot. arg..... m. j
Aqua..... oz viii

M. To be well shaken and a teaspoonful taken every five minutes.

A Severe Case.

Two weeks ago I was summoned to the bedside of Djoahnne Sdtleometzhler. The involute and labyrinthinate tangle of his symptoms made me suspect at first that he had absorbed his own name. But further examination convinced me that he was the victim of typhomalariopneumophthisicotrychinotetanoataxionephreticosplenitis. Owing to the ubiquity of pathogenic bacilli, antiseptics are always indicated, so I exhibited calcium betanaphtholalphamononosulphonate. As the patient suffered from severe non-localized pain I gave orthooxyethylanamonobenzoylamidoquinoline combined with salicylaldehydmethylphenylhydrazine. For his insomnia I gave trichloraldehydphenyldimethylpyrazolene.

His wife asked me what ailed him and what I was giving him. I told her, and she said "yes," and turned very pale.

Upon examining him on the next morning I became convinced that the vital forces had misconstrued the remedies, and that a congerie of retro-absorptions had resulted. I then wrote out the following prescription:

Tetrahydrobetanaphtholamine,
Sodium thioparatoluidinesulphonate,
Orthosulphamidobenzoic anhydride,
Amidoacetoparaphenetidine aa ʒ j.

M. Sig. A teaspoonful every hour.

When the wife presented the prescription to the druggist he instantly dropped dead! The patient is up and about, but something is wrong with his Broca's convolution—he mutters in a multi-syllabic lingo that is intelligible only to modern pharmacal chemists. I am in hiding where the spiral melody of the woobine that twineth blendeth ever sweet, low, soothing, murmurous quadrisyllabic rhythmic rune of the gentle polygonum punctatum.—Dr. Cooper, in the *Medical Gleaner*.

Immunity to Tetanus Induced by Establishing Strychnia Tolerance.

Rummo, the Italian investigator, has recently shown that strychnia, which produces physiological effects very similar to those of tetanus, may be used as a means of establishing immunity in guinea-pigs against infection of tetanus. After establishing a moderate degree of tolerance to strychnia, guinea-pigs were injected with tetanus culture, which was found to be ineffective in most cases, only slightly operative in others, while the controls all died.

THE LIBRARY TABLE.

BOOK REVIEWS.

DISEASES OF THE SKIN; AN OUTLINE OF THE PRINCIPLES AND PRACTICE OF DERMATOLOGY. By Malcolm Morris, F.R.C.S., Surgeon to the Skin Department, St. Mary's Hospital, London, etc. In 12mo, volume of 572 pages, with 19 chromo-photographic figures and 17 engravings. Philadelphia: Lea Brothers & Co. 1894. Cloth, $3.50.

The name of Malcolm Morris is so identified with dermatology that a brief reference to his latest production will insure its recognition by the profession. This work is essentially new and is designed to be both clinical and practical in its scope The chromo lithographs add much to the value of the book, and are well executed. W. H. P.

BLOODSERUM-THERARY AND ANTITOXIN. By George E. Krieger, M.D., Surgeon to the Chicago Hospital. With illustrations. 52 Randolph Street, Chicago: E. H. Colegrove & Co., publishers. Price, $1, net.

Krieger's book on Bloodserum-Therapy is written to introduce the practitioner into the details of the doctrine of Bloodserum-Therapy, the modern method of treating infectious diseases, and to explain the effect observed in the use of antitoxin. It also gives the bacteriologist directions how to prepare the remedy. The text is divided into four chapters, the first speaking on Bloodserum-Therapy in general, its meaning, history and value in medicine. The second chapter reads on the subject of toxins and toxalbumins, the poisonous products of pathogen microbes. The third refers to the use of antitoxin in tetanus, this being the first infectious disease on which the effect of antitoxin has been studied. The subject of the fourth chapter is diphtheria. In reference to this disease special attention is given to the practical administration of the diphtheria-antitoxin, including some valuable suggestions as to the successful use of the remedy.

The book contains 70 pages and 7 half-tones, representing microscopical specimens of various microbes. Bound in full cloth.

ANTISEPSIS AND ANTISTPTICS. By Charles Milton Buchanan, M.D. with instructions by Professor Augustus B. Bernays. Newark, N.J.: The Terhune Company. 1895.

A book of 352 pages. The first 46 pages are devoted to the history of antiseptics from before the Christian era to the present time. Then follows a consideration of the products of vital cellular and bacterial activity, infection, susceptibility and immunity.

The major part of the work is occupied in the enumeration of the various antiseptics, giving their relative values in general medicine, surgery, obstetrics and gynecology. The closing chapter includes the essentials of antiseptics and asepisis with a correlation of opinions from the leadiug surgeons of the age, as to the proper dressings for surgical wounds. W. H. P.

THE THERAPEUTICAL APPLICATIONS OF PEROXIDE OF HYDROGEN (MEDICAL), GLYCOZONE AND HYDROZONE. By Charles Marchand, Chemist. Ninth Edition.

This pamphlet of 200 pages, contains full information on the subject, with elaborate reprints of articles by authoritative contributors to medical literature. It will be mailed free of charge, to physicians mentioning this publication, and sending full address to Charles Marchand, 28 Prince St., New York.

DOSE-BOOK AND MANUAL OF PRESCRIPTION-WRITING WITH A LIST OF THE OFFICIAL DRUGS AND PREPARATIONS, AND ALSO MANY OF THE NEWER REMEDIES NOW FREQUENTLY USED, WITH THEIR DOSES. By E. L. Thornton, M.D., Ph.G. Philadelphia: W. B. Saunders. 1895. Price, $1.25, net.

The aim of the author has been to compile a work of value for both student and practitioner. The composition and strength of all official preparations intended for internal administration are given, together with their solubilities and incompatibilities.

Weights and measures are also considered giving the method of converting the English into the metric system equivalents, and the doses throughout the book are conveniently contrasted in both these systems.

Considerable space is devoted to the grammatical construction of prescriptions, a feature in the art of medicine, of which only too many practitioners are grossly ignorant.

The work is based upon the standard authorities such as the U. S. Pharmacopeia, U. S. Dispensatory and the National Dispensatory, etc.

It will find a place not only with students and beginning practitioners, but makes a convenient reference for men of riper experience.

NOTES ON THE NEWER REMEDIES. By David Cerna, M.D., Ph.D. Second edition. Phi adelphia: W. B. Saunders, 925 Walnut Street. 1895.

The medical press describes from time to time the new remedies, and in cases reported they are also mentioned, but the author has here brought them together in one volume, briefly defined each drug and given an account of its physical properties, physiological action and its therapeutic uses.

The doses are given in the English and French systems of weights and measures.

THE DISORDERS OF SPEECH. John Wyllie, M.D., F.R.C.P.Ed. Edinburgh: Oliver and Boyd. Tweeddale Court.

From October 1891 to May 1892, there appeared in the Edinburgh *Medical Journal* a series of papers which proved to be so valuable that they are now presented to the medical profession in book form. The first part of the volume is devoted to the functional disorders of the speech mechanism. The second part treats of the development of speech and its

mental derangements. The third part describes the diseases of that portion of the nervous system devoted to the production of speech. The book is well illustrated with comparative tables and colored plates.

J. O.

SEXUAL NEURASTHENIA. By George M. Beard, A.M., M.D. Edited by A. D. Rockwell, A.M., M.D. Fourth edition.

In the present edition there is found a new chapter on sexual erethism. The victims of this complaint the editor does not classify with sexual perverts, of whom he says that although a certain few would be glad to be free from the chains that enslave them and seem to be eager for aid, yet the larger proportion are as depraved as the followers of any ordinary form of vice. The physician is compelled to treat these people no matter how distasteful it may be to himself and there is no class to whom so much aid can be given if common sense be combined with good treatment, as to the sexual neurasthenic.

O.

LABORATORY GUIDE FOR THE BACTERIOLOGIST. By Langdon Frothingham M.D.V. Philadelphia: W. B. Saunders, 925 Walnut Street. 1895.

This little pamphlet is intended for use on the laboratory table. Bacteriological technique is briefly described. Directions are given for staining bacteria in cover-glass preparations and insections. The special stains for certain bacteria are given. The last few pages are devoted to the preparation of nutrient media, and the description of imbedding tissue for cutting sections.

TABULAR REVIEW OF ORGANOGRAPHA. By A. L. Benedict, A.M., M.D. Buffalo.

This is a small pemphlet of 21 pages, intended primarily for the use of the classes in the Department of Pharmacy, University of Buffalo. There is, however, nothing to limit its use to any locality or class of students. The little work is not a text book, in the ordinary sense of the word, but is designed to be used with some other botany (Bastin's is especially mentioned by the writer). Running his eyes over the conveniently-arranged tables, the student has a bird's-eye view of the whole subject of structural botany and any point with which he is not familiar he can find defined in the standard manuals. Almost every technical term is exemplified by naming some common plant, and space is left for the addition of other examples by the student. Thus, the Review is especially adapted for use as a guide in field study, and in this particular it is almost without a rival, there being a decided need for some brief, portable reference work for the student who wishes to examine plants in the natural state and to be sure that he has omitted no detail of their structure. Copies can be ordered of the author, and they will be sent postpaid at 25 cents each.

PERISCOPE.

IN CHARGE OF WM. E. PARKE, A.M., M D.

MEDICINE

The Oyster and Typhoid Fever.

Many foods and drinks have been accused at various times of harboring the germs of typhoid fever and giving them up to unsuspecting man; and now, last of all, the succulent bivalve, the oyster, the pride of Maryland, and one of the most important edibles in this gastronomic center, has been accused in other states of giving typhoid fever to those who like the oyster even when transplanted. Many an innocent one has suffered from the guilt of others and here good, fresh, harmless oysters have been taken from their native salt waters and transplanted into fresh, tainted and contaminated rivers, with the result that disease and perhaps death have been brought.

Most germs flourish very badly or not at all in salt or brackish water, and it is only when the oyster is taken from its home and carried to other parts or when it has been too long out of the salt water that it becomes an object of danger. In fact it is like almost every other food in that it is best enjoyed in its native place. The moral of this wholesale poisoning should be a lesson to consumers of oysters to see to it that what they use is obtained from reliable dealers and to beware of salt water food taken too far from the waters. In Germany it is against the law to sell certain varieties of fish except when alive.—*Maryland Medical Journal.*

Apoplexy and Thermogenesis.

Dr. Charles L. Dana concludes his observations as follows:

1. That all intra-cranial hemorrhages, whatever be their lesion, are much more apt to be accompanied with immediate disturbances of temperature than are necrotic processes from embolism and thrombosis. These temperature disturbances in hemorrhages are, in rare cases, a sudden initial fall; then in almost all cases except where the lesion is small, there is within a day or two a rise of temperature of from one to three degrees. On the other hand, in acute softening this initial fall and early rise do not occur unless the process is very extensive or involves the pons.

2. In apoplexy due to hemorrhage, the temperature is greater upon the paralyzed

side than on the normal, the difference averaging about one degree. In acute softening this unilateral difference of temperature does not occur or is extremely slight.

3. The rise in temperature due to apoplectic lesions depends more upon the extent and nature of the lesion than upon its location. Lesions of a hemorrhagic character in the cortex, however, are especially apt to cause a rise of temperature. Lesions in the pons also either of hemorrhagic or softening character, almost uniformly cause a rise of temperature.

4. There is as yet no clinical evidence that lesions of ths basal ganglia or the parts about them cause temperature rises on account of destruction of certain thermic centers; in other words, the clinical and pathological evidence of thermic centers in the human brain, aside from the parts mentioned, is yet inadequate.

5. Finally, I would specially impress upon you the great value, from a diagnostic point of view, of a careful study of the temperature changes after apoplectic strokes. The temperature should be observed on each side of the body, in the rectum, also, if possible. With data thus obtained one can, I feel sure, gain much more positive evidence as to the nature of the lesion in these cases, and I have repeatedly been able to satisfy myself, in my clinical work, of the nature of the lesion by means of the methods referred to. I do not believe that with the help of the numerous factors which we now have in aiding our diagnosis there are many cases of apoplexy in which it is difficult to make a diagnosis. The old-time tabulation of differential points in diagnosis between hemorrhage and acute softening still remains of value. We need, and must use, all the helps possible; but if we, in addition to other methods, carefully apply the thermometric, I am sure we can reach vastly more satisfactory results.

The Use and Abuse of Toothpicks.

The exciting causes of caries of the teeth are invariably external, and among these decomposition of food or of mucus between the teeth holds a prominent place. It follows that removal of such matter must be beneficial. One of the means of accomplishing this is the toothpick, which, judiciously used, is of undoubted value. Food lodges between the teeth form a variety of causes: The extraction of a tooth may lead to those contiguous falling apart and so leaving spaces; improperly filled teeth, such as those left with rough edges and not sufficiently "contoured," that is, built up to the original configuration of the lost part, will form food traps; irregular position of the teeth or recession of the gums—all these will act in the same way. Attention to the dental toilette before company is certainly inelegant, but it is not necessary here to approach the subject except from a medical point of view. Of the materials used as toothpicks the best is the quill with the sharp point removed, but with this, as with all other forms, care must be observed. By indiscriminate application the gums may be so irritated and injured as to cause recession and thus increase the exciting trouble, or inflammation of the tooth membrane may be caused, a most annoying condition, and one in which the still more vigorous use of the toothpick gives temporary relief, only in reality to add fuel to the fire. Metal toothpicks are good because blunt-pointed, but are too thick to pass between teeth at all close together. Wood need only be mentioned to be condemned, for it is a by no means uncommon occurrence for small fibers to become detached and jammed between the socket and tooth, leading to chronic periostitis and even loss of the tooth if the condition is not recognized. An excellent substitute for the toothpick, one having few objections and one which will save many a visit to the dental surgeon, is antiseptic, waxed, dental floss silk, which, passed between the teeth night and morning, will invariably reveal accumulations which have escaped the tooth brush.—*London Lancet.*

The Relation of Hysteria to Insanity.

Dr. Ballett, of Paris, in *Gaillard's Medical Journal*, says that all the mental disturbances of hysteria are not due to it alone, for its association with unsoundness of mind and the fact of a common origin, heredity, he is pleased to consider the changes in the mental machinery almost identical in both, but while so closely allied and often combined they are yet each a distinctive disorder and should be treated as such; and for want of the recognition of this fact, hysteria has often been assigned as the cause of many morbid mental changes for which it, in truth, can not claim an incipient parentage.

Hysteria, while a mental disease, is a too easy or active association of ideas, for those which preside over the manifestations are independent of consciousness and, therefore, there are present two personalities: one the aggregate of the subconscious phenomena, and the other the conscious personality, perverted in part by the effect of the former; thus, by the division of the ego into two separate activities, there may arise from an unconscious impulse a mirrored prototype of the past as observed in the normal physical life.

External Application of Guaiacol in Fever.

S. T. Bartoszewicz, of Professor Lomikovsky's clinic, in Kharkov (*Yujno-Russkaia Meditzinskaia Gazeta*) has used guaiacol externally in eleven febrile cases (four phthisis, two pleurisy, two typhoid, one pneumonia, one pelosis rheumatica, one intermittent), the number of experiments amounting to sixty-five. At first he rubbed the drug with soft flannel into this or that cutaneous area, about five square decimetres in extent. In spite of his using only gentle pressure, the application always gave rise to local dermatitis, with superficial ulcers and scurfing. This complication led him to abandon the frictions in favor of a novel method devised by himself. A piece of linen three square decimeters in size, soaked with twenty-five or thirty drops of pure guaiacol, was applied to the

forehead, back of the neck, or upper part of the chest, then covered with wax-paper, fixed by a bandage, and left *in situ* for one or two hours. It was found that such compresses had exactly the same antipyretic effects as the inunction, while they caused no cutaneous irritation beyond a slight redness. The principal results of the clinical research may be summarized as follows:

1. Of sixty-five cases, only in five the results were *nil*, and only in nine the temperature subsequently rose to the primary height. The maximum effects (2.5° to 3° C.) occurred in phthisis, the depression in a majority of cases varying between 1.2° and 1.5° C.

2. The drug does not give rise to collapse, even in phthisical subjects with large cavities. In these patients, however, the application is almost invariably followed, in from two to four hours, by perspiration and rigors.

3. Compresses are the best mode of application.

4. Chemically pure crystalline guaiacol should be preferred to the ordinary fluid preparation, since it allows a better dosage and does not irritate the skin, even when rubbed in.—*British Medical Journal.*

The Mechanical Treatment of Chronic Constipation.

Dr. F. E. LeMarinel believes (*Jour. de Med. de Chirur. et de Pharmacologie*), that the mechanical treatment should be the treatment of choice in a large number of forms of chronic constipation. The manœuvres of massage comprise three forms—frictions, pressures, and percussions. In addition, various, active and passive movements are undergone—flexon, extension, abduction, adduction, paronation, supination, rotation and circumduction.

The various forms of constipation which are likely to be benefited are: (1) From anæsthesia of mucous membrane; (2) from muscular paralysis; (3) from induration of the stools, and (4) from mechanical obstacle. The contra indications are: (1) Acute inflammation of intestines, peritoneum, peri-intestinal cellular tissue, or of intra-abdominal veins; (2) ulcerations (round, tuberculous) of stomach or intestines; (3) tumors of the alimentary canal (sarcomata, carcinomata, polypi); (4) voluminous fæcal masses of stony hardness. An interesting comparison is given of the value of diet, habit, purgatives, hydro therapy, injections, electricity, various medicinal methods, with that described by the author, the general conclusion being that of all these methods only one can be compared to the mechanical, and that one is electricity. But when one considers the question from the standpoint of success, massage shows figures which are not surpassed by electricity. As to facility of application, massage is superior in that it does not require any apparatus, and can be applied equally well at the house of the patient as at the office of the physician. Further, massage is better borne than electricity, and particularly by children. A series of 147 cases are reported, the treatment being that advocated in the paper. The care shown in the report, the apparent accuracy of diagnosis, the fullness of detail, give an especial value to the clinical histories. In the cases cited, those of the synoptical table, and eleven in detail, 158 in all, radical cure was obtained in about 90 per cent. The final conclusions are:

Mechanical treatment takes rank among those therapeutic agents whose action is most energetic upon the circulation, the respiration, and general nutrition. It can modify the abdominal circulation, and cause certain foreign congestions, notably those which are met with in abdominal plethora, to disappear. Under its action the muscles acquire an increase in volume and strength. It is the best curative agent in constipation dependent upon muscular paresis or paralysis not of central nervous origin, or upon diminished sensitiveness or anæsthesia of the mucous membrane due to local causes. Finally, it is formally contra-indicated when constipation is due to acute inflammatory lesions or to tumors.

Treatment of Certain Gastric Affections.

From a recent article of Dujardin-Beaumetz (*Bulletin General de Therapeutique*) and quoted from *The Therapeutic Gazette*, we cull the following: Every individual suffering from disease of the stomach in whom there exists a true arrest of gastric function, or a tendency to such a condition, should on going to bed lie on the right side, in order to facilitate the passage of the food into the duodenum. Lying on the left side gives rise to the formation of a large amount of gas, accompanied by a regurgitation into the œsophagus of the products of digestion. Patients should make use of warm drinks. The usefulness of these is evident; in fact, warm water is one of the best means to excite muscular contractions in the stomach, but it is liable to cause vomiting. It is therefore preferable to administer infusions of chamomile, anise seed, or some other similar aromatic substances, and as warm as thay can be borne. In these cases the ingestion of mineral waters is likewise useful. Alkaline waters in small doses, half an hour to an hour after meals, increases the secretion of gastric juice and its acidity; hence their advantage in cases of dyspepsia attended with a subnormal amount of hydrochloric acid in the gastric juice. Even in those cases where there is an excess of this acid, the alkaline waters do good, and in these instances through a different mechanism: they influence the mucous membrane of the stomach, so as to diminish its congestive and inflammatory condition, which is often the origin of the hyperacidity. The same may be said in regard to the use of bicarbonate of sodium, which should be administered during or after meals. A very good adjuvant in these cases of slow digestion is massage; this measure not only enhances muscular contraction of the walls of the stomach; but also increases the secretion of gastric juice, and manifestly modifies for the better chemical changes during digestion.

The Physical Diagnosis of Gall Stones.

Gebhardt observes that the attack usually begins four or five hours after the chief meal, that is, shortly after the entrance of the stomach contents into the duodenum. According to the size and position of the stone after it has passed into the common bile duct, distention of the gall-bladder may be recognized at once, or later (when the gall-bladder has been copiously filled, or not at all). The swelling lies between the right parasternal line and the interior axillary line, mostly a little to one side of the right rectus muscle. If the gall bladder is much distended it may give rise to errors in diagnosis. This distention only takes place in a minority of the cases. It may be absent owing to the smallness of the gall-bladder, or to the obstruction being incomplete, or lasting too short a time. It occurs in severe attacks, or in those who have had repeated attacks The commencement of the attack may last a couple of hours without pain, during which time the gall-bladder may be palpable. The shrinking of the swelling shows the end of the attack.

This is due to local peritonitis, and it explains the continuance of pain. An ice-bag is more useful here than warm applications. The liver may swell after severe attacks and fever be present. Attacks may occur with pain and fever, but there is neither swelling of the gall-bladder nor of the liver, and no stone is found in the stools. It is thought that the stone slips back into the gall-bladder but other possibilities exist. The swelling of the gall-bladder may be due to obstructions having other causes, but it does not occur in cardialgia, nor in heptic colic of purely nervous origin. This latter is observed in tabes, hysteria, multiple sclerosis, and may even be accompanied by jaundice. When, after several attacks no stone is found, no friction sound heard, and no swelling of the gall-bladder felt, cholelithiasis may, with tolerable certainty, be excluded, and neurohepatic colic may be assumed with great probability. *British Medical Journal.*

Opium in the Treatment of Diarrhœa of Infants.

Dr. Floyd M. Crandall (*Gaillard's Medical Journal*) says: In diarrhœa much opposition to opium has arisen during recent years, due chiefly to misapprehension as to its proper applications. While its improper use may do much harm. it is an agent of the greatest value and should not be abandoned. It is contra-indicated: 1, in the first stages of acute diarrhœa before the intestinal canal has been freed from decomposing matter; 2, when the passages are infrequent and of bad odor; 3, when there is a high temperature or cerebral symptoms are present; 4, when its use is followed by elevation of temperature or the passages become more offensive. It is indicated—1, when the passages are frequent, with pain; 2, when the passages are large and watery; 3, in dysenteric diarrhœa, together with castor oil or a saline; 4, in late stages, with small frequent nagging passages; 5, when the passages consist largely of undigested food, and the bowels act as soon as food is taken into the stomach.

The dose should be as small as possible, sufficient being given to relieve pain and check peristalsis. It should not be added to the ordinary diarrhœa mixture, to be repeated at short intervals. It should be given alone and at intervals sufficient to allow the effect of one dose to subside before another is given. This interval will rarely be less than four hours.

Chloroform During Sleep.

The following case is of interest as bearing on the question whether a sleeping person can be chloroformed without awakening.

The reporter was asked to take two teeth out for a girl aged seven, and as she is very timid and excitable, to give her chloroform. On going to her home he found her lying on her back in bed sound asleep. Having poured about two drachms, probably more, of chloroform on a folded towel, he gradually brought it to about two or three inches from her mouth and held it there. She went on breathing quite quietly, and neither coughing nor making any unwonted movements. In a very short time she was so well under its influence that her hand fell down when raised and the conjunctiva was insensible to touch.

She was then lifted out of bed, carried into another room and laid on a sofa without her giving any sign of consciousness. On opening her mouth, however, she put up her hands and turned her head on the pillow. More chloroform was given, and almost immediately she was in a state of complete anæsthesia and the teeth were extracted. She was easily aroused, but almost momentarily fell asleep again, and slept for two hours. When she awoke she was much astonished to find her teeth were out.—*Therapeutic Gazette.*

Growing Pains.

Growing pains, defined as pains in the limbs caused by and during rapid growth and sometimes so severe as to give rise to growing fever, have been diagnosed by the author less and less frequently as the years rolled by, until the vanishing point was reached. Cases which have been classed together under this name are the following:

Myalgia from Fatigue.—This is the commonest variety, usually about the knees and ankles after unusual exertion. They are probably due to autoinfection brought about by excessive production of *effete* materials in the blood and their inefficient elimination. Elevating the limbs and rubbing with the palm of the hand in a direction toward the heart, relieving venous stasis and facilitating a supply of healthy blood to the exhausted muscles, promptly relieves the pain.

Rheumatism.—This is second, if not first, in frequency. There is slight pain in the joints, little or no swelling, and very mild fever, and hence the true cause is not recognized; but rheumatic endocarditis frequently develops in these cases.

Diseases of Joints and Bones of the Lower Extremities.—Cases of hip joint disease and suppurative epiphysitis of the upper end of the fibula, diagnosed by the laity and allowed to go on untreated, are related under this heading.

Fevers, accompanied by pains in the limbs, in one instance proving to be inception of typhoid fever constitute this class.

Adenitis.—Here, again, the mother still supposes that the lad of sixteen years suffered from "growing pains," but he was treated for gonorrhœa and a sympathetic bubo.

The malady "growing pains," with its frequent concomitant growing fever, like its congener disorders of dentition, as a separate morbid entity exists principally as an article of faith. The complaint still maintains, however, a strong hold of the lay mind, and forms an extremely common lay diagnosis which is often the cause of much suffering, and even death, by leading to the neglect of curative measures at a time when they are most effective.—*P. B. Benne in Arch. Pediatrics.*

Chyle Cysts of the Mesentery.

Dr. W. H. Wenning reports a case of this disease in the *Lancet-Clinic* and says on the subject that the origin of these cysts is very uncertain. In some instances undoubtedly rupture of a lymphatic, in consequence of an accident or unusual exertion, may lead to the formation of a cyst. Here, in all probability, the fluid effused between the layers of the mesentery causes some irritation and the formation continues to separate the layers from each other. In other instances a rupture may lead to effusion of chyle into the free abdominal cavity. Single cysts might very easily arise in the first mentioned manner. When there are multiple cysts, however, the origin is more probably due to stenosis of the thoracic duct. Mendes de Leon thinks that, although a stricture of this nature might cause widening at the bottom of the duct, it does not sufficiently explain the formation of a cyst. Besides this, in cases of stenosis, collateral channels for the conveyance of chyle into the blood have been observed. Virchow, Rokitansky and Kilian have demonstrated the fact that the entire closure of the thoracic duct may give rise to considerable enlargement and crowding up of the chyle vessels. From the nature of the conditions found in my case I am inclined to believe that stenosis and obliteration of the thoracic duct was the cause of the formation of these numerous cysts Drs. Jones and Cleveland, who made an autopsy immediately after death, were unable to find the thoracic duct. There were no cysts, in the true sense of the word, if we look upon the sac as an adventitious structure, for the chyle seemed to be surrounded by the walls of the mesentery alone. When this membrane was pierced, or, as I have shown above, simply touched, it would collapse. There was, however, evidence of considerable inflammation of the serous membranes.

A Case of Diphtheritic Vulvitis in a Child.

The patient, a girl, aged one year, first came under my observation on September 11, 1894. The mother stated about five days previously the child had become irritable and restless, and showed other signs of pain, which were referred to the genital region; these symptoms were aggravated during micturition.

An examination of the vulva revealed several patches of false membrane covering anteriorly the internal portion of both labia majora and nymphæ, and invading the urethral orifice. The membrane was firmly attached and grayish white in color. The mother stated that two fatal cases of diphtheria had recently occurred in the house in which she resided, the last one about one week before her child was taken ill. There were no throat symptoms. A bacteriological examination made by Dr. William H. Park revealed the presence of the diphtheritic bacilli.

The patches disappeared under the use of local applications—chiefly peroxide of hydrogen and bichloride of mercury—and the child made a good recovery. At no time while the patient was under observation were any marked constitutional symptoms noted.—*Dr. Gnichtel in Journal of Cutaneous and Genito-Urinary Diseases.*

OBSTETRICS.

Labor and Heart Disease.

Tarnier (*Journal des Sages Femines*) notes that in heart disease all great and sudden efforts put the patient in peril, and labor is no exception to the rule. Running upstairs, racing to catch an omnibus or train, and sexual intercourse may all cause fatal syncope. The danger of labor is not special in this sense; it is dangerous in heart disease simply because it involves much effort. Tarnier induced premature labor in a lady who was subject to advanced heart disease. Notwithstanding all precautions, she became moribund in the course of the labor. Directly she died, he turned and delivered a live child, which survived. A woman was brought to Tarnier's wards in January, 1894, in labor with advanced heart disease and asystolism; she was apparently dying. Immediately about 300 grams of blood were withdrawn and the symptoms of suffocation diminished. The patient grew calmer. As it was extremely advisable to bring on labor quickly, as the forceps is apt to fatigue the patient, and as, in particular, the child was dead, the basiotribe was applied and delivery effected. A few days later the mother was doing very well.

Premature Delivery of Dead Child Induced by Acute Appendicitis.

The article by Dr. P.F.Munde (*N. Y. Med. Rec.*, Vol. XLVI.), with above title, has been followed by the reports of similar cases from other observers. Acute appendicitis may be

the cause of abortion and should always be considered when symptoms of appendicitis exist. The error should not be made of treating a case of abortion, in which high temperature and pain situated in right iliac region occur after expulsion of the fetus, as one of acute pelvic peritonitis. More recent reports show that the high temperature due to the appendicitis is not necessarily the cause of death of the fetus.

Operative interference for the relief of the co-existing appendictitis should be decided on as soon as the patient has recovered from the immediate shock of the abortion.

The Operative Treatment of Backward Displacements of the Uterus.

E. W. Cushing (*Gynecological Transactions*, Vol. XVIII.) draws the following conclusions from a study of the above subject:

Many cases of retroflexion and retroversion, if uncomplicated, cause little or no disturbance, and, therefore, require no operation.

Severe retroflexion in virgins, giving rise to symptoms sufficiently severe, is better relieved by operation.

Cases that resist simple measures, as the pessary, are usually found to have some com plication that necessitates operation. The only operations werthy of trial are the Alexander-Adams operation of shortening of the round ligaments by abdominal section and ventro-fixation. Alexander's operation is subject to the following limitations: freely movable uterus, exact diagnosis, favorable anatomical conditions. When these conditions are not present an abdominal section had better be done, and the case treated according to circumstances. If no complications are present, the uterus may be secured in anteposition by shortening the round ligaments internally, and by placing at each cornu uteri a suture passing through the abdominal wall. This operation is regarded by the author as equally safe, and on the average more reliable than the Alexander procedure.

The Diagnosis of Pregnancy in the Early Months.

Landau (*Deutsche Medicinische Wochenschrift*) believes that the exact estimation of the beginning of pregnancy is not possible as, apparently, the ovulation occurs independently of menstruation. The size of the uterus is in the early months also an unsafe guide. The form and consistence of the utertus is more reliable. It is enlarged evenly and in transverse diameter, so that the anteflexion is increased, the vaginal portion is drawn up, the vagina elongated, and the anterior vaginal wall appears tenser than otherwise. The consistence is softer, the sensation being as though the examining finger was pressed in soft butter, the finger passes in, finds no resistance, and returns no impression. Hegar's sign may be recognized in 80 per cent. of the cases; the same sensation as is perceived by palpating the lower uterine segment may be obtained by palpating the tubal angles. The consistence of the anterior and posterior uterine wall is irregular, usually the anterior is softer and looser than the posterior, which probably has some relation with the attachment of the placenta. In the examination attention should be paid to the fact that one cannot recognize all thrse signs at one tims, as the uterine contractions soon occur and interfere. It is necessary to examine frequently. The other usual signs of pregnancy should also be taken into account.

Landau's paper was founded upon over 200 cases of pregnancy, from the third to the twelfth week, and refers only to the normal position of the uterus.

Leucorrhœa in Young Unmarried Women.

In the treatment of leucorrhœa in young unmarried women, instances frequently occur in which the usual practice of making an examination to ascertain the condition of the pelvic viscera is so obnoxious to the patient, or is so firmly opposed, that the physician is forced to abandon it, and have recourse to medicine.

In such cases Dr. Slocum has learned to depend upon the scientific action which cantharides appears to exercise upon the cells constituting the genital as well as the urinary system. It is probably by direct stimulation of the cell just to the point of successful resistance that the benefit is secured, as the dose is very small. Strangury, or other unpleasant symptom, has not been produced. The action of the drug has been so uniformly satisfactory that when it fails, such result forms a strong basis for suspecting the presence of something more than simple hyperemia or mild inflammation. Lessening of the discharge is sometimes noted within five days, but in several cases of profuse discharge of four years' and longer duration, the treatment was not successful until after a month's persistent use.

The formula which has seemed the best, contains also the tincture of ferric chloride, and dilute phosphoric acid. These though probably modifying the action of the cantharides, are only adjuvants. Following is the usual form of administration:

Tincture of cantharides.....	96 minims.
Tincture of ferric chloride	160 minims.
Dilute phosphoric acid.....	160 minims.
Sprup of lemon.....	2 fluid ounces.
Water sufficient to make.....	4 fluid ounces.

M. Dose.—One teaspoonful, in water, after meals.

Albuminuria of Pregnancy as a Cause of Death of the Fœtus.

In twelve cases of the albuminuria of pregnancy recently observed by the author all the children were born in bad condition, only five of them surviving. In six the death was directly traceable to the toxæmia. In four cases multiple hemorrhages had occurred

into the placenta. These patients all came to him, however, in advanced stages of uræmic intoxication.

Speaking of the frequency with which these hemorrhages are observed in albuminuria, the author mentions an instance in which the weight of the clots equalled that of the placenta itself. He emphasizes the importance of early treatment, and especially the use of the milk diet in the interests of the child as well as the mother. In 250 cases recently studied by Bridier there was a fœtal mortality of 20 per cent., notwithstanding some treatment. The much larger mortality in Oui's cases, in which the milk diet had not been employed, is significant.

The induction of premature labor, the author thinks is indicated only after the milk treatment has failed to relieve the symptoms.

In the discussion, Chaleix laid stress on the importance of diuresis for the elimination of the toxines. In his hands the hypodermic injection of the physiological salt solution in large quantities had, in conjunction with the use of milk given through a stomach tube when the patient was unable to swallow, proved of marked service in desperate cases. The quantity of urine was increased, and both the maternal and the fœtal condition improved.

Dangers of Curettage.

During a recent discussion on this subject in the Obstetrical and Gynæcological Society of Berlin, six cases were reported which show how dangerous this operation may be in certain conditions of the uterus. The principal danger is that of perforation; but it is not equally great in all cases. In metritis the uterine tissues are resistant, and afford a solid floor upon which the curette may be carefully moved backward and forward with slight risk of perforation. The uterus is in a very different condition after abortion or labor. The tissues are profoundly modified, and the thickness of the walls greatly diminished. The dimensions of the cavity are irregular, and there is danger, even with the greatest precautions, of penetrating the peritoneal cavity. The cases reported by the German surgeons were principally of this kind, and in several of them the wound was so large that a loop of the intestines entered the cavity of the uterus. These cases are instructive, as they show that this operation should not be undertaken lightly, even by skillful men. They demonstrate what we have long known, and what cannot be too often repeated, that the uterus in involution is ruptured with the greatest facility; but these accidents should not deter us from performing curettage when it is necessary to prevent infection from retained placental debris.—*Union Medicale.*

The Etiology of Puerperal Fever.

The *University Medical Magazine* gives the following deductions from Dr. Herman's remarks in a discussion of puerperal fever:

1. Puerperal fever is produced by microorganisms which get into the system through wounds made in childbirth.
2. These organisms are transferred by contact. They are not inhaled or swallowed.
3. The transferrence of organisms is prevented by cleanliness, and the organisms are killed by antiseptics.
4. The hands are the usual poison-bearers; next in frequency clothes and instruments.
4. Investigation of a particular outbreak of puerperal fever should begin with inquiry into the precautions taken by doctors, nurses, and mid wives to secure the cleanliness and disinfection of their hands, clothes and instruments.
6. There is no such thing as self-infection with puerperal fever. The causes supposed to produce "autogenic" puerperal fever produce, in lying-in women defended antiseptics from septic poison, only trivial illnesses.
6. The inhalation of sewer gas causes in the puerperal woman the same symptoms as in other persons. There is no good evidence that, in women defended by antiseptics from septic poisoning, it produces symptoms like those of septicæmia.
8. The poison of erysipelas of the skin produces in lying-in women erysipelas of the skin, and no other illness. But the poison of the disease known as phlegmonous erysipelas of cellular tissue produces puerperal fever.
9. The poison of scarlet fever produces in lying-in women scarlet fever, and no other illness.

Extra-Uterine Pregnancy at Tenth Month: Placenta Inserted on Intestine.

Houzel describes (*Ann. de Gynec. et d'Obstet.*) a case in which the period was last seen on May 1, 1892. A violent attack of hypogastric pain, with dysuria, set in early in November. On February 10th, spurious labor set in and lasted four days; a decidua appears to have been passed. On March 15th, she remained undelivered and still felt pain; there was fever, but no diarrhœa. The sound passed three inches into the empty uterus. The outline of the child could be very distinctly seen through the parietes. On March 18, 1893, abdominal section was performed. The peritoneum was of a singular green tint. The fœtus, slightly macerated, lay immediately underneath; its head was deeply engaged in the left iliac fossa, and much deformed from pressure. It had developed in the left tube, and the sac had evidently ruptured during the previous November. The placenta had become attached to the small intestines, and was still free from an retrograde change. The fœtus was removed, and the cavity which it had occupied was filled with iodoform gauze. On March 28th the placenta began to separate. There was some constitutional disturbance. On April 5th the last piece came away, and convalescence was thenceforth rapid. The drainage tube was removed at the end of April; the orifice of its track closed in a few days.

Pregnancy at the age of Fifty-nine.

In the *Gazette de Gynecologie*, Dr. Depasse reports the case of an aged-looking lady with white hair, supposed to be suffering from a large uterine fibroid, whom careful examination proved to be pregnant. She was confined of a boy at the full term, and was able to nurse him; she wearned her son on her sixtieth birthday. She was a widow and had a married daughter aged forty. The age was verified by a certificate of birth. Such late pregnancies are extremely rare.

Symphysiotomy.

Professor Leopold gives (*Annales de Gynec. et d'Obstet.*) the following conclusions as regards symphysiotomy.

1. Symphysiotomy, as formulated by Morisani, is a great clinical victory. But the operation should not be vulgarised. For the dangers it bears with it are very real, and in consequence it cannot replace perforation or even version with the general practitioner.
2. Primiparæ should not be subjected to symphysiotomy.
3. As regards the future state of women operated upon, there is as yet not time to pronounce definitely.
4. Hemorrhage and vaginal lacerations command great prudence, and affect the after-treatment.
5. As a rule symphysiotomy is applicable to pelves of from 7.5 to 6.5, or perhaps 6 centimeters in the conjugata vera. These cases should be sent to the clinics. A general practitioner under the same conditions should think of the mother and perform perforation.
6. In contracted pelves of 7 centimeters, if the medical man is consulted in time, premature labor should be induced. If too late for this then let the labor proceed naturally, deep the membranes intact until the external os is fully dilated. If the labor does not end naturally it is still possible to deliver children of good size at term with success, by version and immediate extraction if the following conditions are present: Membranes intact, complete dilatation, and the use of Walcher's position. (The patient has her legs hanging over the side of the table).
7. Exceptionally with these latter conditions all present and favorable, if version and forceps at the brim do not give any hope of effecting delivery, symphysiotomy may be used with these diameters.

Gestation Complicated by Appendical Abscess.

McArthur (*American Journal of Obstetrics*) reports two cases of pregnancy complicated by abscess of the vermiform appendix. One case was advanced to four and a half and the other case to five months. Both cases were operated upon and the abscess cavity drained before general peritonitis had occurred.

Abortion resulted in the first case the morning following operation, and in the other case not for two days later. The lessons of the cases detailed may be set forth in the following propositions:

1. That the largest proportion of all cases of acute suppurative appendicitis are seen by the surgeon only forty-eight hours or more after their onset.
2. That in the great majority of such cases an abscess exists outside of the appendix and whose walls are made up of the structures which surround the appendix at the onset of inflammation, and which are held together by plastic lymph.
3. That profound sepsis, either chemical or bacteriological, will sooner or later induce fetal death and miscarriage.
4. That after the third month of gestation a portion of the wall of the appendical abscess is usually formed by part of the right wall of the uterus.

From the fact that after opening the abscess and draining its cavity there is a shrinking of its wall and a disturbance of the relationship of parts which existed prior to operation, with the risk of infection from such cause, and as it seems most likely, for reasons mentioned, that the fetus cannot be saved, it seems good practice to lend every effort to save the mother, and to, therefore, before closing the abdominal wound, empty the uterus and establish those relations of the structures which we desire to maintain after closure of the abdomen.

ARMY AND NAVY.

CHANGES IN THE U. S. MARINE HOSPITAL SERVICE FOR THE FIFTEEN DAYS ENDING APRIL 27, 1895.

Lieutenant Colonel Dallas Bache, Deputy Surgeon General, to be Assistant Surgeon-General, with the rank of Colonel, April 18, 1895.

Major David L. Huntington, Surgeon, to be Deputy Surgeon-General with the rank of Lieutenant Colonel, April 18, 1895.

Captain William C. Shannon, Assistant Surgeon, to be Surgeon with the rank of Major, April 18, 1895.

NEWS AND MISCELLANY.

American Medical Society Meetings.

Owing to the meetings of the American Medical Association and the Medical Society of the State of Pennsylvania which fall this year upon May 8th and May 22nd, regular meeting days of the Philadelphia County Medical Society, the latter society has substituted for these two meetings one meeting on May 15th, for which an extremely interesting programme has been arranged.

The State Board of Medical Examiners.

The State Board of Medical Examiners, representing the Medical Society of the State of Pennsylvania, will meet in Philadelphia, corner of Broad and Pine Streets, and in Pittsburg, Council Chambers, on Tuesday, June 18, 1895, at 2 P.M., to examine applicants

for license to practice medicine in Pennsylvania.

Blank applications and all necessary information can be obtained from the Secretary of Internal Affairs, Harrisburg, Pa.

H. G. McCORMICK,
President of Board.

Third International Congress of Dermatology, to be held in London, August 4th to 8th, inclusive, 1896.

President—Jonathan Hutchinson.

Vice-Presidents for the United States—Dr. Duhring, of Philadelphia; Dr. White, of Boston; Dr. Nevins Hyde, of Chicago; Dr. Bulkley, Dr. Keyes and Dr. Fox, of New York. For Canada—Dr. F. Shepherd, of Montreal; Dr. Graham, of Toronto.

Treasurer—Malcolm Morris.

Executive Council—Chairman, Mr. Hutchinson.

Committees—Reception—Chairman, Dr. Radcliffe Crocker.

Museum and Demonstration—Chairman, Dr. Stephen Mackenzie.

Bacteriological—Chairman, Dr. Sims Woodhead.

Secretary to Section for Syphilis—Ernest Lane.

DR. J. J. PRINGLE, Secretary-General.
23 Lower Seymour Street, London, W.

REGULATIONS.

1. All duly qualified medical men, British or foreign, or others interested in science invited by the Council, who shall have paid the fee of £1 sterling (the equivalent of £1 sterling is: French, 25 francs; German, 20 marks; Italian, 25 lire; American 5 dollars), and who shall have enrolled themselves, shall be members of the Congress and entitled to the Volume of Transactions.

2. The official language of the Congress shall be English, French and German, but with the permission of the president, members may express themselves in the language with which they are most familiar.

3. The proceedings of the Congress shall be embodied in a Volume of Transactions, edited by the Executive Council.

4. Communications relative to membership, papers, or other matters connected with the Congress, should be addressed to the Secretary General, Dr. J. J. Pringle, 23 Lower Seymour Street, London W., or to one of the foreign secretaries.

5. The fee for membership shall be payable in London, at or before the opening of the Congress.

It will greatly facilitate the work of executive if the fee is forwarded as soon as possible after the 1st of May, 1896.

6. Members who are unable to attend Congress shall receive the Volume of Transactions.

7. The subjects treated of shall be of two orders—

(1). Those selected beforehand by the Executive Congress and introduced by gentlemen chosen for that purpose by the Council.

(2). Those selected by individual members themselves.

8. Subjects selected for debate by the Council shall take precedence over those selected by the members.

9. The sittings of the Congress shall take place from eleven to one in the forenoon, and from three to five in the afternoon of each day.

10. There shall be clinical demonstrations of patients every morning from nine to half-past ten and every afternoon from two to three.

11. Members contributing papers must submit an abstract of them to the Secretary-General on or before the first of May, 1896, which will be printed either in full or in part, embodied in the general programme of the Congress which will be distributed at its opening.

12. At every debate precedence will be given to gentlemen who have communicated beforehand their intention to take part in it.

13. No papers lasting more than twenty minutes will be permitted. Speeches will be strictly limited to ten minutes each. MSS. of the papers read must be left with the Secretary-General before the end of the sitting. The Executive Council shall decide as to the entire or partial publication of such papers in the Transactions of the Congress.

J. J. PRINGLE, Secretary-General.
GEO. THOS. JACKSON, New York,
Secretary for the United States.

ORIGINAL ARTICLES.

INTRA-CAPSULAR FRACTURE OF THE HIP-JOINT.*

G. A. BAXTER, A.M., M.D., CHATTANOOGA, TENN.

The fracture is usually at the small part of the neck, though occasionally in the very young there may be a separation of the head. The line is more often transverse but may be in any direction, transverse, oblique, irregular, and in one instance reported, spinal. There may be interlocking of fragments, though this is very rare; when it does occur it is the lower frament into the upper one. Generally a large, smooth, convex surface presents on one fragment and a depression on the other. The head may be comminuted by the lower fragment.

The usual displacement is of the shaft upwards, backwards and outwards, with or without laceration of the capsular ligament; however, this is varied, in the proportion of one in every five cases, to an upward direction of the lower fragment. This displacement is a gradually increasing one, from one-half to one inch at first, increasing during the first two weeks to one-and-a-half to two inches, In impaction there may be a twisting of the one or other fragments. A complete over-lapping of fragments may occur.

The position of the limb is almost pathognomonic of this fracture; the foot widely everted with shortening and a total inability (usually) to bear the slightest weight upon it, so that if the patient is in the upright position the body is supported on this side by the hands and not the leg. A further investigation will show an inability to lift the foot forward, as in the act of walking, or to raise the heel from the bed when lying down. In the impacted variety this may be modified to the extent of allowing the patient to stand upon the feet for a while, or to walk some distance before the leg gives way. There is pain, varying in character, but especially severe upon the slightest movement or pressure at the point of injury. There is a flattened condition of the hip on the injured side. Crepitus can generally be obtained by rotation inwards with slight extension to bring the fractured ends into apposition. This is not a constant symptom, and the search for it should always be carefully made lest an irreparable injury be inflicted by unlocking a possible impaction. The trochanter rotates in a shorter radius, acting from the point of fracture rather than the head of the bone. It is above Nelaton's line in the triangular space described by Dr. Bryant, and nearer a line drawn in the axis of the body on the injured side. (Morris' measurement.)

Histologically, the neck of the femur is constructed of cancellous tissue surrounded by compact tissue, the latter varying in thickness at different parts of the neck as well as on its anterior and

*Read before the Tennessee State Medical Society, April, 1895.

posterior aspects. On the anterior aspect, the compact tissue is thinnest where it joins the head, and becomes thicker posteriorly until it joins with the intertrochanteric line, which itself is compact tissue. On the posterior aspect of the neck the compact tissue is thickest where it joins the head, and becomes gradually thinner as it proceeds backwards and outwards, losing itself in the cancellous structure underneath the great trochanter, which is really an apophesis for the attachment of the external muscles and adds little to the strength and resistance of the bone at this point. This makes the two weakest places in the bone just posterior to the head in the small part of the neck, where the anterior layer of compact tissue is thinnest, and at the base of the neck just above the trochanter, where the posterior layer grows thinnest before losing itself in the cancellous tissue underneath the great trochanter. These are the points at which fractures usually occur, hence we are forced to recognize these histological differences as predisposing causes to fractures at the upper end of the femur.

Beyond the age of fifty, the bone undergoes radical change in its structure, particularly at this point. The canals grow larger, the compact tissue thinner, the spongy tissue being filled with fat. The size is not altered, but the specific gravity becomes less and the resisting power of the bone to strain or force greatly diminished. This is not an absorption of animal tissue alone, but a senile atrophy; the changes which effect this condition being, chiefly, the enlargement of the canals and the thinning of the compact tissue, which latter becomes so thin at times as to be faintly translucent. Hence we find that the great majority of these fractures occur beyond fifty. To this cause is attributed its greater frequency in women, as the changes referred to occur earlier and proceed to a greater extent in women than in men.

Disease also, such as rhumatoid arthritis, contributes to or causes this fracture, though more often the head of the bone is absorbed in this disease in the hip-joint.

Another change which occurs with age in both sexes, is an increasing acuteness in the angle between the neck and the shaft of the bone, the neck being found at times almost at a right angle to the shaft in the very old. The bone would undoubtedly stand a less degree of strain or violence with the neck at an acute angle with the shaft than at an oblique angle, but the fact of such change has been disputed by Bodet after investigations which led him to assert that the changes in the angle as a result of age were of so few degrees that as a causation it would have little effect. It is possible, however, that the difference in the angle between the sexes may explain, in part, the greater frequency of this fracture among women.

The anterior-posterior diameter in the neck is smaller than in the shaft of the bone, and smaller within the capsule than at the base of the neck.

The great prominence of the trochanter major, with direct violence, transfers directly to the weakest portion of the bone, force which would otherwise be modified or dissipated by the thick, elastic cushion of muscles which cover the joint.

The depth of the acetabulum makes it act as a fulcrum for the head of the femur, increasing the strain upon the neck in force transmitted from below, in direct blows upon the trochanter and in strain from sudden, violent, muscular action, transforming force which would otherwise result in a strain or dislocation into fracture.

The exciting cause of fracture of the neck of the femur varies from the slightest degree of muscular strain transmitted through the limb from below, or in leverage, the limb being caught in adduction or abduction, to the greatest amount of direct force received directly upon the trochanter major. Stumbles, missteps, the jar received in stepping from the curbstone to the street, catching the foot in the carpet in turning or walking, loss of balance, twists of the body in emptying a pail of water, turning over in bed, bending to one side to keep from falling, falls on the knees, side of the thigh or on the buttock, muscular action in the movements of the thigh in adduction, abduction or rotation—all have been held responsible for a degree of violence sufficient to produce the intra-capsular fracture. Malgaine asserted that exaggerated muscular action plays an important causative part at all times in the production of these fractures; in some cases the fall being secondary and in consequence of fracture produced by muscular action. The intra-capsular fracture more often occurs from the action

of indirect force and lighter degrees of violence, and in the aged and infirm; without the capsule fractures occur more often in the young and healthy, and the exciting cause is more generally great and direct violence received directly on the trochanter, possibly transmitted from below.

The general question of repair of this fracture by bony union, has been a subject of difference between surgeons; the difficulty of its satisfactory solution being a divergence of opinion in the interpretation of the processes which have taken place in the specimens of this fracture in existence. Owing to absorptive changes in the head and neck at the seat of fracture, it is said to be impossible to determine beyond cavil: 1st, whether the bone has been broken, or whether the changes are not simply the result of absorption; 2d, whether, conceding a break, they were intra-capsular fractures purely; or, 3d, is the union by fibrous or bony tissue?

There can be little doubt that in early life, up to the age of seventeen years, there have been cases of repair by bony union, but these cases are supposed by some to have been separation of the epiphyseal head with impaction, not fractures at the small part of the neck, or those rare cases with little or no periosteum torn and consequently very little if any displacement of fragments. The great majority of surgeons of the present day, claim that union takes place but very rarely, if at all; though close fibrous union does occur at times. The head of the bone, however, maintains life through a branch of the internal circumflex artery in the untorn portion of the periosteal covering, it being a fact that the periosteum is seldom torn completely around, the anterior-inferior portion escaping, and is capable of and does produce callous.

In view of these facts, even barring those rarer cases of impaction (which would undoubtedly have a better chance for union of this nature even though the periosteum was torn completely around, for the cancellous structure has reproductive power of its own), it does seem that with close and proper approximation and with absolute immobilization it might be possible to get some kind of bony union here. The real difficulty, unquestionably, is not the inability of the fragments to unite through defective vitality, but the heretofore impossibity of complete immobilization, and the chance of approximation we were forced to accept as the best which could be done. The changes in the neck of the bone which predispose to fracture, certainly do not of themselves decide this question in the negative, though, in any special case, either incomplete approximation, deficient immobilization, or the completeness of the periosteal tear might do so.

The attainment of close fibrous union of this fracture, giving a fair degree of usefulness to the limb, is an undoubted possibility. My own conclusions are that could approximation and immobilization be maintained, there is nothing to prevent union by bone at this point, since, 1st, the upper fragment is alive and capable of granulation; 2nd, approximation, heretofore, with most of the methods devised (extension and rotation inward or outward, as the case may require for eversion or inversion of the foot) has been almost chance work, owing to our want of control of the upper fragment and its general displacement inwards by the pressure of the lower fragment, and our neglect of local control of the upper end of the lower fragment. These methods correct the upward and backward displacements, but they leave an outward displacement due to the continued action of the hip muscles in this direction, still unconquered. Approximation being still incomplete immobilization could do no good whatever; 3rd, the rarer cases of reported union have been, must have been (with a chance approximation possible only), either cases where the periosteal covering was untorn or torn but slightly; cases of impaction, or cases of fracture partly within and partly without the capsular ligament.

Whatever the possibility in these cases, the result, in the past, has been an almost universally bad one—disability more or less, the patient suffering all degrees of functional interference from a permanent confinement in bed, to the use of a crutch or cane—with close fibrous union and little deformity but always with an amount of shortening from one-half to two inches. The limb may even retain considerable usefulness when union has failed entirely, owing to the support which the Y ligament and the quadrator femoris gives to the body.

The differentiation between intra and

extra-capsular fracture depends much upon the history of the case, the symptoms differing more in degree than in character, and it is asserted that an actual diagnosis between the two is a matter of little moment since the treatment is practically the same in both varieties. Such reasoning should be condemned, as the hypothesis upon which it is based is untrue. The treatment for both these varieties of fracture need not necessarily be the same, or rather the treatment which accomplishes a good result in the extra-capsular fracture has hitherto been an almost total failure in the intra-capsular, and there are points of differentiation of value for self-satisfaction and prognosis. Without being exhaustive, a few of these symptoms will be enumerated that the contrast may be established for the purpose of precaution both in prognosis and treatment, as will be shown hereafter to be necessary.

The intra-capsular fracture is nearly always seen in the very old (fifty and upwards), while the extra-capsular fracture is more often seen before this period. The fracture within the joint is most common in women, while the fracture without the joint is equally common to both sexes. The degree of violence in the intra-capsular variety is usually very slight, which is seldom the case in the extra-capsular variety. The internal variety is produced from below (generally) by force transmitted through the limb, the external by force directly upon the trochanter. In the intra-capsular variety the shortening is small at first, gradually increasing with the progress of time; in the extra-capsular the shortening is immediate and complete. In the one case we have pain, redness and swelling referred to the hip joint, in the other to the trochanter.

The only dislocation with which intra-capsular fracture would be likely to be confused, is the pubic. This would give shortening and eversion, but the shortening would be greater and the eversion less in the dislocation. In intra-capsular fracture the displacement, if it exists, would be a drawing upwards, backwards and outwards of the lower fragment, while in dislocation the head of the bone would be felt in the groin. In fracture we would have extra mobility with probable crepitus; in dislocation, diminished mobility and absence of crepitus. The pain existing in fracture would be ascribed to the joint, in dislocation to the groin.

In those exceptional cases where the foot is inverted in this fracture, the appearance of the hip alone (flattening) would indicate the impossibility of dislocation in the upward and backward direction. In any degeneration, as that of tuberculosis or rheumatoid arthritis, the history of previously existing disease of this character should lead to a proper conclusion.

The consideration of treatment involves the question of the possibility of union by bone at this point of fracture in the femur. An avowal of hopelessness of this point means helplessness, and it would become our duty, after a short interval for the subsidence of acute inflammatory symptoms, to abandon all restraint or confinement instead of making a pretense of that which, under this supposition, can never be accomplished.

But is such a supposition correct? Many surgeons reasoning from the almost universal result, non-union, have jumped to the conclusion that there could be none; and have attributed the failures to a want of vitality in the upper fragment of the fractured bone. This may be, and doubtless is the cause of non-union in some few case where the violence has been very great, producing comminution of the upper fragment or tearing the periosteum completely apart around the whole circumference of the bone; but, that it is not universally the case is proven by the few cases of union of bone which have taken place in early life, by the preservation of vitality in the upper fragment in all cases not comminuted, with even partially preserved periosteum, or uncomplicated with general conditions of disease tending to retard or defeat bone repair. It is further proved by the cases of cartilaginous union, as this is but the uncompleted process of union by bone. That the changes occurring as the result of age simply, is not a hindrance to union is proven by the fact that union by fibrous tissue is not limited to the cases which occur in early life, but in old age as well.

It is a well known fact that a fracture seldom occurs here, so severe or extensive that there is not some portion of the periosteum remaining untorn. This untorn portion is usually on the under and anterior aspect, and in it is rescued, for the

nutrition of the upper fragment, one of the branches of the internal circumflex artery. This branch and the blood through the ligamentum teres is sufficient to give a healthy vitality to the detached head of the bone, and if it is ample to do this, it is equally plain that there should, under other proper conditions, be a production of callous.

Some of the specimens of fibrous union in existence, show a want of perfect approximation and a bridging over of an intervening space by fibrous union in spite of imperfect approximation, the fibers taking an oblique course rather than a straight direction with the axis of the neck portion of the lower fragment. This seems to prove that with perfect approximation and retention there would have been unquestionably bony union where fibrous union was accomplished in these cases, as the failure to preserve these two requisites (approximation and retention) is the main cause in the production of fibrous, rather than bony, union elsewhere.

The acknowledgment of the possibility of callous production between the fragments of this fracture, leads to the confession of an attainable bony union, and we ask ourselves, what are the conditions required? To answer this question we must again inquire as to the displacement. In by far the greater number, the displacement is upwards and backwards (shortening), with external rotation (oversion); in rare cases upward and forward displacement and internal rotation; in either case the upper fragment is pushed to one side by the lateral pressure of the displaced lower fragment. In this condition, it is pertinent to ask, does extension and inward rotation (the correction of eversion and shortening), or extention and outward rotation in those rarer forms of displacement, correct the deformity entirely? Unquestionably they do overcome shortening and correct eversion by opposing gravity of the limb and counteracting the effect of the rotator muscles in twisting the limb; but they do not overcome the outer displacement, as made by such muscles as the gluteus medius on the upper end of the lower fragment, or bring into apposition with the already partially displaced upper fragment, except it be by the merest chance; this chance being sufficient to account, together with impaction, for the very few cases of partial approximation as evinced by ligamentous union. Evidently then there is something more required in the treatment of this fracture than extention and rotation in the reduction, and extention, rotation and counter-extention for its retention, which form the only principles maintained in nearly all the ordinary splints in common use for its correction. There needs must be, in addition to these principles, local internal pressure over the upper end of the lower fragment to overcome the remaining force in outward exertion and to bring it into relation with the upper fragment at all, besides continued pressure in line with the axis of the neck to keep it there. The bulging trochanter seems the most convenient place to place such pressure, and it is possible to imagine this attained by any of the splints of the straight variety to which has been previously adjusted a pad for the trochanter, or with the suspension variety with pad or even sandbag pressure. It is even possible that the sandbags ordinarily used with the latter variety to keep the body straight, has by pressure, unconsciously to the surgeon, contributed towards a nearer approximation and consequently ligamentous union in a few cases. That surgeons of the past recognized something unattained, is evidenced by the number of retention splints which have been devised; and that they were correct is proven by the almost total failure to obtain union by any of them. It remained for Dr. Nicholas Senn to correct this cause of non-union, and also to perfect the plaster splint so as to leave little to be desired in meeting the indications present. If we may hope for intracapsular union at all, we must look for it through this apparatus, or one fulfilling these indications equally as well.

I quote a description of this device from De Costa. "To secure perfect immobility at the seat of fracture, it is not only necessary to include in the dressing the fractured limb and entire pelvis, but it is absolutely necessary to include the opposite limb as far as the knee and to extend the dressing as far as the cartilage of the eighth rib. The splint is incorporated in the plaster dressing and it must be carefully applied, so that the compress, composed of a well cushioned pad with a stiff unyielding back, rests directly upon the trochanter major, and the pressure, which is made with a set-

screw, is directed in the axis of the femoral neck. Lateral pressure is not applied until the plaster is completely set. Syncope should be guarded by the administration of stimulants. As soon as the plaster has sufficiently hardened to retain the limb in proper position, the patient should be laid upon a smooth, even mattress, without pillows under the head, and in non-impacted fractures the foot is held in a straight position and extention is kept up until lateral pressure can be applied. No matter how snugly a plaster of Paris dressing is applied, as the result of shrinkage it becomes loose, and without some means of making lateral pressure it would become necessary to change it from time to time in order to render it efficient. But by incorporating a splint in the plaster dressing, this is obviated and the lateral pressure is regulated day by day, by moving the screw, the proximal end of which rests on an oval depression in the center of the pad."

Concerning the final results in these cases but little more need be said. The results for good union in the past, as has been said, are practically negative. As to full restoration, it has been asserted that there never has been a proven case of full restoration with complete bony union, full length, natural position and strength. While this is true and a large number of these cases remain permament fixtures in bed, there is yet a large proportion who regain, under even the unfavorable conditions, a large amount of functional activity. Either the broken ends of the bones became smoothed by rubbing against each other, or the lower fragment makes for itself a new socket of fibrous tissue and the outer fasciculus of the Y ligament and the tendon of the obturator support the weight of the body upon the shaft below. The permanent condition varies from that of bedridden helplessness to crutches or cane, but always with perceptible shortening and consequent lameness. I must enter my vigorous protest against the do-nothing policy so frequently followed in the very old, where accepting death or non-union as inevitable, the patient is made as comfortable as seems possible under such a policy, in any position as to the limb, under the hopeless thought that it is all useless anyway. Such policy is worse than it seems without thought, for it contributes directly to the production of hypostatic pneumonia and fatty embolism; subjects the patient to the tortures of continued confinement in bed and ends in concomitant results at this age—uncleanliness, bedsores and exhaustion, when all might be releived by a proper application of the Senn device, at least until time had eradicated the immediate results of such an injury (active inflammatory action), and transferred him to that safer and less helpless state of non-union which has been the finale in these cases, thus giving to him at the same time whatever chance remained for him for the production of bony or fibrous union. With this splint the patient can be handled with impunity.

The manner of death in this fracture, when it occurs, is from hypostatic pneumonia, fatty embolism or exhaustion; neither needs elucidation here.

In conclusion, let me say this paper is not intended as an eulogy on a man, but is written to emphasize a method, which if rightly understood and appreciated will bring about marked change in the final results in this fracture.

ACUTE CROUPOUS PNEUMONIA.*

J. S. CAIN, M.D., NASHVILLE, TENN.

I have selected this common, every-day and probably somewhat "shelf-worn" disease as the subject of my essay, for two reasons: First, It is a common disease of universal prevalence, with which every practitioner has had more or less to do practically; with which every one is more or less familiar, and has usually well defined ideas as to its nature and treatment. It is, therefore, a subject which should elicit a general discussion and develop individual experiences and observations,

*Read before the Tennessee State Medical Socity, April, 1895.

which is always more valuable in societies than recitations from books and standard authorities. Second, I have selected it because I do not believe that the profession is agreed as to many vital points connected with it; I have seldom heard the subject discussed, in a medical association, or even in a professional consultation, that there were not as many different, and often conflicting, opinions as to its nature and treatment, as there were speakers; each believing that he alone was correct. If my humble effort shall arouse a thorough discussion of this important disease by this learned body (an is my hope) I shall be very much disappointed if the same honest differences of opinion do not exist here as elsewhere.

As there can be but one true theory upon these points, this great diversity argues that many must necessarily be in the wrong; and that there exists a necessity for more information upon the subjects; which can be only arrived at by free comparison of individual views and observations. These are my apologies for presenting a subject which in these times of new ideas and fads, may be looked upon as somewhat trite and obsolete.

I will further explain that in treating this subject in the manner essential to the requirements of the twenty minute rule, I shall not attempt system or elaborateness, but shall devote my remarks to points connected with its nature and treatment, about which there may exist diversities of opinion and differences in practice; and leave out of consideration such points and theories as are very generally conceded by the profession. I shall not allude to the other varieties of pneumonia; and shall, in this variety, omit everything which is not explanatory of its nature or suggestive of its treatment.

Croupous Pneumonia is so-called on account of the inflammatory process which attends it, being of the peculiar nature known as croupous inflammation, which is characterized by an exudate upon the surface of the mucous membrane involved, of a fibro-plastic material poured out under the stimulation of the inflammatory action.

This exudate instead of forming a coating or pseudo-membrane as it does upon free and more open surfaces under similar conditions, here accumulates in the lung alveoli and inter-vesicular terminals of the bronchiæ, filling up, rendering them solid, and obliterating for the time the porous and spongy lung parenchyma, and constituting the characteristic feature of the disease, *heputization* or *solidification*. This condition, being always found embracing a lobe of a lung, or a large area of tissues in continuity in one or both lungs, has given to the disease another of its synonyms, *lobar pneumonia*; which stands in contradistinction to lobular, catarrhal, insular of broncho pneumonia.

The extent of lung involvement, indeed the existence of the disease almost in toto, depends upon predisposing influences, such as have lowered dynamic forces or impaired vital resistance. Hence the disease occurs almost wholly in persons laboring at the time of its invasion, under the enervating or vitiating influence of some other form of diseases, such as measles, whooping-cough, typhoid fever la grippe, etc.; or in those whose health and vital resistance have been impaired by previous attacks of this or some other disease; also are those predisposed whose vital resistance has been impaired by exposure, irregular habits and general debilitating causes; and above all are those predisposed who have lingering in their systems certain vices, such as malarial toxæmia, and that engendered by habitual abuse (or rather use) of alcoholic liquors. In a long term of practice in a malarious region, I have observed that a great proportion or the pneumonia subjects of winter and spring were of the old malarial subjects of the previous summer and fall.

It is a disease of very general prevalence and is not confined to any particular climate or locality. It occurs most frequently in winter and spring. Males are more frequently affected than are females; and the right lung more frequently than the left. It was at one time believed that young children were almost exempt, latter day observations prove the reverse.

While the formerly entertained opinion, that cold, sudden changes in temperature and exposure are the efficient exciting causes of this disease is still adhered to by many, and probably to some extent conceded by all, still the dominant opinion of the day is that the disease has for its exciting cause a micro-organism of peculiar morphological characteristics, called by Fraenkel, *Diplococcus Pneumoniæ*.

Probably there can be no question but that this organism is always found in great numbers in the morbid tissues of the disease under consideration, and that the pure cultures produced somewhat similar conditions in experiments upon animals. The same micro-organism, is found in the normal secretions of the salivary glands and buccal cavity. It remains to be more fully demonstrated whether it is a mere concomitant of the disease, stimulated into pathological activity and perverted characteristics by the peculiar disease influence, or whether it is really an etiological factor in the disease.

The *Micrococcus Pasteuri,* differing in many essentials from the former, has been largely experimented with of late years by Dr. Sternberg, and is believed by him and many others to be the real pneumonic germ. The frequent occurrence of the disease in an epidermic form has been seized upon as evidence of its microbic origin. This to my mind, is far from conclusive. The predisposing influences are most usually endemic in character, rendering all persons living in a certain locality more or less receptive and liable to fall victims in an outbreak in which the exciting cause might be catarrhal, atmospheric or telluric, and giving to the outbreak as pronounced epidemic characteristics as though it was of microbic origin. The limits of my paper will not permit me to discuss further the microbic origin of the disease. The omni-presence of the organisms in the diseased tissues, and their power to reproduce the disease, if true, seem conclusive of their causative nature.

The anatomical changes of this disease are to be studied from three separate and distinct standpoints or stages, which are usually denominated, the first, second and third stages; or to speak more in pathological terms, the stage of hyperæmia or engorgement, the stage of solidification or hepatization, and the stage of resolution; each embracing pathological phenomena peculiar to itself, and giving rise to signs and symptoms of individual and peculiar significance, calling for study in detail.

The first stage marks the gradual progress from the normal to the abnormal; from the physiological to the pathological. It is one of hyperæmia extending over a large but usually well-defined area of lung, brought about by some disease-producing agent and exerted, evidently, through nervous influence. This local manifestation is evidently the expression of a systemic cause. The initial chill in adults, convulsions in children, succeeded in both by pyrexia in advance of all appreciable local disturbance, marks the disease as a true lung fever, no matter what may be the primary agent which exerts its depressing influence upon the nerve centers.

During the first stage, the blood vessels distributed around the lung alveoli, after a period of simple hyperæmia, become engorged and congested to the stage of blood stasis. In the early changes peculiar to this stage, the mucous membrane of the alveoli and contiguous bronchical terminals becomes dry, thickened and inelastic, giving rise to the hoarse, irritable, dry cough of this period. Later on, as the engorgement progresses, there occurs a slight serous effusion with the commencement of plastic formation, which proceeds to constitute the subsequent leading characteristic feature of this disease. This plastic material being distributed over the alveolar walls, renders them tenacious and causes their opposing sides to adhere when brought together by the mechanical pressure of the surrounding engorged tissue in the act of expiration, to be torn apart again by the filling of the alveoli in each inspiratory movement, giving rise to the auscultatory physical sign of the first stage, *crepitant râles.*

Extreme engorgement at this stage produces two other characteristic phenomena; the extravisation of red corpuscles by diapedesis through the capillary walls into the air vesicles, which, mixing with scant secretions in small bronchiæ, gives the characteristic symptom, *rusty sputum;* while the more solid character imparted to the normally porous and spongy lung tissue by the great vascular engorgement, renders it a better conductor or sound, transmitting the to and fro movement of the air through the bronchiæ, and producing, probably the first significant physical sign, *bronchial respiration.*

All of these conditions belong to the first stage, and progressively tend in one direction, resulting, unless resolved by nature or arrested by treatment, in more or less perfect and impermiable solidification of that portion of lung involved in the area of disease influence or patholog-

ical storm center; thus giving rise to dullness or flatness on percussion, with negative auscultatory signs.

This condition of solidification results from the progressive exudation of fibroplastic elements into the lung alveoli and inter-vesicular bronchiæ, until they become completely filled or clogged up by the coagulation of this material, constituting *red hepatization*, or the second stage of the disease, which is usually reached from the third to the fourth day after the initial chill.

About the completion of the condition of red hepatization, or often preceding it, occurs another vascular condition, the appreciation of which is important in the treatment at this stage. I allude to an intercurrent complication known as collateral œdema, which grows out of extreme engorgement and interference with the circulation in and around the disease focus, and consists in a serous effusion into the connective tissue in the immediate neighborhood of the disease, effectually and suddenly cutting off from respiratory function a much larger lung area than is involved in the actual disease and producing sudden death from apnœa.

This complication of pneumonia occurs in the better class of subjects, those possessing good plasticity of blood and strong dynamic force. These cases when detected require a line of treatment peculiar to themselves. The condition of red hepatization is termed the second stage of croupous pneumonia. I am inclined to look upon it, however, as the climax or perfection of the first stage, but shall not contend for so radical a change in the usually accepted classification of stages.

The condition of red hepatization is usually one of short duration; the processes of resolution often commencing while portions of lung in the immediate neighborhood are yet in the stage of engorgement, presenting to the diagnostician signs conflicting and significant of different conditions apparently from the same locality; this same perplexing complication occurs again when the disease spreads or invades peripherally as it sometimes does.

As a very general rule, the disease does not remain longer than a few hours at the point of red hepatization before the retrograde changes characteristic of *resolution* set in. There is one condition in which I have seen the state of red hepatization remain for days without any appreciable effort at resolution. I allude to these cases of croupous pneumonia which supervene as an intercurrent complication of la grippe. In this condition I have seen the stage of resolution delayed for several days and the lung remain apparently unchanged. I offer no explanation.

Red hepatization or solidification, which I have designated as the climax or perfection of the first stage, is simply the filling up the alveoli and terminal bronchiæ in the diseased region, with a plastic material elaborated from the blood serum and leucocytes which have found their way into these cavities in consequence of the overdistended condition of the blood vessels surrounding them, and acting under a specific pathological stimuli. The plastic material thus contained in the lung parenchyma is firm, solid and adherent to the alveolar walls and, when cut, the hepatized tissue presents a red, rough and granular surface.

The process of resolution consists in retrograde and reparative changes, amongst the first notable of which is the bleaching out or disorganization of the red corpuscles, and the increased migration of leucocytes into the alveoli, changing the scarlet red appearance of the inter-vesicular matter and giving to the diseased tissue a grayish appearance, termed *gray hepatization*. The further progress of resolution consists in fatty and granular changes, and in breaking down by processes of liquefaction or solution of the matter in the alveoli and bronchial terminals, not well understood.

Portions of this plastic matter are partially dissolved, and expectorated in the form of granular masses and minute tube-casts, others are wholly liquefied, and expectorated, at first mixing with the excessive migrating leucocytes—constituting muco-purulent, later on mucoserous-discharges.

Early in the stage of resolution, as the air commences to re-enter the re-opening air vesicles, and in passing through the small bronchiae filled with tenacious matter, a minute bubbling sound is created both on inspiration and expiration, called sub-crepitant râle, which marks the commencement of resolution. Later on, when the larger bronchiae become filled with the same material, the same process produces large mucous râles.

These signs, with the re-appearance of resonance over the diseased region indicate the progress of resolution. The expulsion of all products of inflammation by expectoration, a re-establishment or normal circulation in the blood vessels embraced in the area of actual disease and its surroundings, with the repair of bronchial and alveolar epithelium, constitutes the cure, and embraces the periods of resolution and convalescence.

In approaching the treatment of acute croupous pneumonia, it may not be amiss to lay down a few general propositions.

The disease is specific in character and self limited in nature. When not prolonged by intercurrent complications, intensified by overpowering predisposing agencies, or exaggerated by excessive suppurative processes or ulceration in the lung tissues, the tendency in to run a course of from seven to ten days, from the initial chill to the establishment of convalescence.

It is altogether a disease of a low rate of mortality, in which nature is capable of accomplishing a cure in a large proportion of cases, no matter what ordinary treatment may be pursued or whether treatment is instituted or not.

This accounts for the general success which we hear reported from the most diverse and conflicting methods. From the homeopathic to the more potent colored water; from the spoliation of blood letting, mercurial ptyalism and tarter emetic to the conservative and supporting treatment of dietectics, quinia ammonias and strychnia, all report marvelous successes and low mortality.

While it is a disease with a generally favorable prognosis, yet it offers a rare field for intelligent medication. All do not recover, even under the best treatment; and especially when intensified by complications and vitiating influences, does it offer a scope for study and investigation unsurpassed in pathological study. There are a limited number which may be saved or lost, by proper or improper treatment. Indeed there probably is no disease calling for more nice and accurate knowledge of pathology and therapy than this, and none in which the intelligent physician can get a surer return for his knowledge and skill.

When complicated, it always terminates in a crisis; usually a critical sweat marks the advent of defervescence and permanent favorable change.

In the treatment of this disease, it is well to bear in mind that there are two great pathological processes to be kept in view:

First, the filling up of the air vesicles by the coagulation in them of a fibroplastic material resulting from a pathological condition brought about by a systemic poison operating through nerve influences upon an area predisposed to disease by other agencies. In other words, that the disease as we recognize it, is but the local expression of a systemic cause, and that the rate of mortality or the risk of life may practically be calculated by the extent of this process in the first stage, or that the danger to life in croupous pneumonia bears a direct ratio to the extent of *red hepatization*.

The other process is that of *resolution*, which sets in usually upon the completion of hepatization and is entirely one of repair, or nature's effort to remove pathological products, in which she is aided or retarded by the dynamic forces and vital resistance of the patient, or the absence of these.

It follows as a logical sequence, that the indications for treatment in the first stage are to counteract and prevent as far as possible, the tendencies to this process of solidification, and to antagonize any vice or toxic principle which may be depressing to vital resistance.

The indications in the second condition are to assist nature in her effort to rid the lung tissues of their pathological products, which is accomplished by liquefaction and expectoration; and to support the system under the irritation and spoliation consequent upon these efforts.

In carrying out the indications in the first stage, it will be well to bear in mind that the fibrinous coagulum contained in the air cells is the product of fibrinous elements in the blood, effused into the air-cells from the over-distended inter-vesicular capillaries coming in contact with ferments contained in or furnished by the leucocytes which have migrated into the field of disease.

Then it follows that the lowering of blood pressure and arrest of arterial tension and consequent engorgement of lung capillaries, will tend to prevent the effusion of fibrin principles, as well as the mi-

gration of leucocytes, and to that extent will retard or prevent the accomplishment of this stage. Again fibrin elements in the blood vary greatly under different conditions. They are always the product of retrograde changes in disease and of destructive metabolism in health, and are always exaggerated in inflammatory diseases, especially the one under consideration, hence such treatment as will lessen or prevent the elaboration of those principles in the blood, or neutralize them after formation, at the same time lessening the labor of the lungs becomes a disideratum in the treatment of the early stage.

Hence that class of remedies known as defibrinators and depressants of blood tension, have naturally been looked upon as valuable agents—if such were the trio, blood-letting, mercurials and tartar emetic, so popular with the profession a quarter of a century ago, and yet regarded with great favor by many. These remedies would constitute the ideal treatment in all cases of this disease, if it were not for their spoliation and permanent prostrating effects. Hence, except in well-selected cases, they are contra-indicated on account of the strong tendency to adynamia or asthenia (often erroneously termed typhoid) which demands in the latter stage all of the vital powers and reserve forces of the patient to meet the pathological ordeal. These remedies, however, are not only applicable but constitute the only reliable treatment in a limited number of cases. These are the dynamic or sthenic cases of pneumonia, occurring in persons with good integrity of blood and muscular contractility—in such as collateral edema is to be dreaded.

For a long time the lowering of blood pressure and liquefaction of fibrin products in the blood, have been sought to be accomplished by a line of treatment less depressing to the vital energies. The first is accomplished by the use of heart sedatives, such as veratrim viride and aconite; and the latter, by the employment of muriate of ammonia. This, I believe, is yet the most popular treatment of the day, in the early acute stage.

The objection to these powerful heart sedatives is that their effects are more or less permanent, leaving a heart inertia which proves detrimental to recuperative action in the more advanced stage.

Again, I fear that their paralyzing effect upon vaso-motor influence favors sluggish circulation and blood stasis in the lungs, at the same time that it lessens the *vis a tergo*, and thus often more than neutralizes the good effects they would otherwise accomplish.

I have been accustomed to endeavor to overcome this evil effect in these useful remedies by combining them with stimulating doses of quinine, which drug I regard as invaluable in all stages of this disease, being an arrester of molecular changes. It lessens the accumulation of fibrin elements in the blood and also, as established by the well-known experiments of Singer, it not only lessens the number of leucocytes but also arrests their amœboid migration from the blood vessels; thus striking at the very foundation of the processes which result in fibrinous coagulation and cell proliferation, which, as before stated, constitute the danger features of this disease. Besides, by its stimulation the brain, vaso-motor, respiratory and cardiac centers when given in small doses, it overcomes in a great measure the objections to verat. viride and aconite.

These remedies can be given in combination in capsules if desired, or can be given separately for the effect.

There can be no possible objection to the use of muriate of ammonia in the early stage. It may be given in from five to ten grain doses, every three hours, in solution, or, preferably, with sprup of wild cherry or tolu added; also an appropriate quantity of syrup or wine of ipecac.

Squills and other stimulating expectorants are to be discarded at this stage, to be taken up later on.

Tincture or infusion of digitalis is a remedy to which many practitioners are exceedingly partial, in the first as well as in the subsequent stages. Just how we can reconcile the employment of an agent which is universally conceded to be a heart stimulant and an intensifier of blood-pressure, in the treatment of a condition where we have acknowledged that the lowering of blood-pressure is indicated, appears parodoxical, and yet I believe that it is a valuable remedy. No doubt, there are others present who employ it as I do, from whom I hope to hear the rationale explained more fully.

Calomel given in several small doses, early in the disease following by a gentle purgative, I regard as essential for reasons which

must be obvious to all, but I would not press its use to the point of ptyalism, as was formerly the custom. When the temperature runs very high, despite the use of heart sedatives, there can be no objection, in my judgment, to the employment of one of the coal tar antipyretics to reduce it within reasonable bounds, but their employment further than this should not be persisted in.

When pain is a prominent and distressing symptom, which is usually the result of pleural complication, opiates may be employed with extreme caution.

Sinapisms, dry cups and warm fomentations to the affected side, each have a limited field of usefulness.

Blisters should not be employed in the early stage. Here I am convinced a great diversity exists in the practice of different physicians first, as to whether blisters should be used at all in pneumonia; next, as to the stage at which they should be employed. I have changed my opinion several times upon this subject and may change again, but at the present writing, with the lights before me, I would not employ them in the acute stage.

In treating this disease during the stage of resolution, different indications are to be met. Such agents as will aid in liquefying the products of inflammation, encourage expectoration, stimulate respiratory function and sustain and support the vital forces, are to be employed. Many of those used in the first stage are to be dispensed with, while others are to be retained with additions thereto. If blood-letting, tartrate of antimony, veratrim viride and aconite have been employed, they are to be discontinued. Calomel should be employed only occasionally after the first stage, for the purpose of maintaining the liver in functional activity and to protect the kidneys against vicarious labor.

Local treatment is no longer required except in the advanced stage of resolution, when, as is sometimes the case, the flagging vital powers seem to come to a halt. I have used large blisters over the diseased region with prompt and decided benefit. In some way not understood by us, blisters in this condition seem to arouse a renewed effort in the exhausted forces of nature.

The muriate of ammonia is to be exchanged for the carbonate, which is a needed, diffusible stimulant and respiratory tonic, as well as a solvent of the offending plastic material.

Quinine is to be kept up in the same dosage recommended in the early stage, for its tonic and stimulating effects.

Stimulating expectorants are to be employed now. Squills, senega, sanguinaria and ipecac may be selected. If all were used in combination, probably the prescription could not be improved.

As the stage of resolution progresses and expectoration becomes profuse, strychnia, with one of the mineral acids, may be advantageously added to the treatment.

Here digitalis may again be brought into requisition, to meet threatened heart inertia, but I believe that its greatest usefulness is in the early stage.

In cases of sluggish progress or delayed resolution without any evident cause, iodide of potassium may be added to the expectorant compound, in five-grain doses, three or four times a day.

A well-regulated dietary is as essential in this stage as medicine. Milk, meat-juices, broths, eggs, etc., should be allowed to the digestive capacity of the patient. When appetite and digestion are defective, they should be stimulated and aided by the use of bitter tonics, pepsin and dilute muriatic and phosphoric acids.

During the entire disease, the emunctories should be maintained in functional activity, the bowels gently open, the kidneys fortified against excessive work in eliminating waste matter, by the employment of some of the alkaline mineral waters.

The skin has an important work to perform, not only as an eliminator, but as a dispenser of hyperpyrexia through the evaporation of its secretion. Hence sponging with tepid and cleansing lotions should be kept up at seasonable intervals.

General glandular inertia, especially intestinal, with dryness of mouth, during resolution may be greatly relieved by the stimulating effects of turpentine, in five drop doses, three or four times a day.

Last, but not least, careful hygienic observance should not be neglected.

The open admission of pure air is a desideratum, but in such manner as to protect against currents and draughts.

CONTRIBUTION TO THE STATISTICS OF TYPHUS (TYPHOID) FEVER.*

DR. BERG.

1626 cases are considered, which were treated in the Leipsic Medical Clinic, from the beginning of 1880 to August 1, 1893. Comparisons are made with similar statistics compiled by H. Schultz during the great Hamburg epidemic of 1886–7. Since the end of 1888, all the cases have been systematically treated with lukemarm baths, varying to cool showering (*Uebergiessung*) in case of extensive lung involvement or marked disturbance of the sensorium, providing the recognized contra-indications did not forbid the use of baths. In most cases, not more than one or two baths daily were ordered.

Although there were marked variations from year to year, and from month to month, the following table shows the well-known preponderance of cases in the early autumn. [Probably a similar table compiled for the northern cities of the United States would show the maximum point to be delayed about a month. A. L. B.]

TOTALS, 1880–92.

Jan.	122	July	136
Feb.	96	Aug.	252
March	97	Sept.	240
April	78	Oct.	193
May	71	Nov.	150
June	75	Dec.	88
	Grand total		1598

All statistics agree that the great majority of cases of typhus occur in autumn and a comparatively small number in spring. [It will be noticed from the appended table that the years 1882, 1888 and 1893 form minima in an irregular curve. It would be interesting to note if a periodicity in the occurrence of epidemics could be demonstrated by a study of statistics for a long term of years. A. L. B.]

1880—113	1887—103
1881—178	1888— 82
1882— 88	1889—194
1883—194	1890—137
1884—138	1891—117
1885—120	1892— 97
1886—110	1893— 46

(estimated from the number reported up to August 1st, taking the average ratio for the entire series).

In only a limited number of cases was the etiology apparent. One hundred and forty-seven patients came from houses in which typhus had occurred; twenty-three female nurses contracted the disease at the hospital, and seven patients, entering the hospital for some other trouble developed typhus. But, of the seven, a local cause could be positively excluded in the case of four who developed typhus five to eight days after admission, and probably, in the case of the remaining three who developed typhus ten or twelve days after admission. (Can we be so positive as to the time necessary for incubation?) Various authorities give the following statistics of "typhus domesticus." [Apparently this term means typhoid fever developing in the hospital; in this sense, the percentage of Berg's total list of cases is 1.5; if we take the term to apply to all cases showing an apparent contagion or infection due to residence, Berg's percentage would be over ten. A. L. B.]

Liebermeister, for Basal,	2.4 per cent.
Alexander, for Breslau, .	3.6 " "
Goth, for Kiehl, . . .	5.5 " "
H. Schultz, for Hamburg,	.57 " "
Murchison, for London Fever Hospital, . .	.3 " "

A repetition of the disease was positively demonstrated in only one of our cases, that of a man who had typhus eleven years previously. Another case in which the patient was seized with typhus two months after the end of the first attack, is probably to be considered as a re-

*Condensed translation from the German Archives for Clinical Medicine, April 11, 1895, by A. L. Benedict, A.M., M.D., Lecturer on Digestive Diseases, Dental Department, University of Buffalo.

lapse. The frequency of repeated attacks is given as follows:

H. Schultz, ...	2.2	per cent.
Beetz, ...	1.8	" "
Freundlich, ...	2.2	" "
Goth, ...	2.	" "
Ours only, ...	.05	" "

According to age, the 1626 cases of typhus were divided as follows:

1	year—	3 cases.	.19	per cent.
2	" —	2 "	.13	" "
3	" —	7 "	.44	" "
4	" —	10 "	.63	" "
5–9	" —	46 "	2.80	" "
10–14	" —	86 "	5.4	" "
15–19	" —	359 "	22.4	" "
20–24	" —	434 "	27.	" "
25–29	" —	315 "	19.5	" "
30–34	" —	167 "	10 4	" "
35–39	" —	106 "	6.61	" "
40–44	" —	41 "	2.5	" "
45–49	" —	29 "	1.8	" "
50–59	" —	20 "	1.25	" "
60–69	" —	10 "	.63	" "
70–80	" —	5 "	.32	" "

Between the ages of 15 and 29 1108 cases occurred, almost two-thirds of the total number, and between the ages of 15 and 35 as much as 86 per cent. H. Schultz has found in a series of 3686 cases, that 56.8 per cent. occurred between the 15th and 25th years, and that 80.04 per cent. were included between the 15th and 35th years. According to Liebermeister, 19 per cent. of all typhus cases occur between 16 and 20; 58 per cent. between 21 and 30; 16 per cent between 31 and 40; thus 93 per cent. occur between 16 and 40. Freundlich tabulates 87.7 per cent. between 15 and 35. Other authorities also arrive at similar results.

According to our statistics, sex has an influence as well as age; in every period of life the male patients predominating. We have in all 917 men—62.2 per cent., and 709 women—37.8 per cent. Other authorities, for example—Murchison and Griesinger—maintain that both sexes are equally liable to typhus, and explain the majority of men by the circumstance that women are more unwilling to go to a hospital. The influence of sex does not extend to children, for we count 80 boys and 82 girls under 15, and H. Schultz finds 250 boys and 201 girls. However, there are not lacking authorities who claim that typhus occurs twice as frequently among boys.

Of our 1626 cases 243, 12.7 per cent., died. The proportion of fatal cases in the different years is shown in the following table:

Year.	Patients.	Died.	Males.	Females.
1880	113	22	13	9
1881	178	21	15	6
1882	88	6	3	3
1883	121	22	11	11
1884	138	10	7	3
1885	120	22	14	8
1886	110	10	7	3
1887	103	17	10	7
1888	82	9	8	1
1889	194	22	13	9
1890	173	31	14	17
1891	117	27	9	18
1892	9.	16	7	9
1893	28	8	4	4 (8.mos)
'80–'93	1626	243	135	108

The mortality varies greatly with different years. In 1888 18 per cent. died; in 1884, on the contrary, only 7 per cent.

The mortality, according to age, is as follows, Schultz's statistics for the Hamburg epidemic are added in the last column:

Years.	Patients.	Deaths.	Per Cent.		Per Cent.
1–4	22	3	13.6	—At Hamburg	4.
5–9	46	8	13.		6.4
10–14	86	7	8.1		8.1
15–19	359	35	9.7		8.7
20–24	434	60	13.8		7.7
25–29	315	37	12.		
30–34	167	25	15.		12.3
35–39	106	30	28.3		11.5
40–44	41	12	29.2		14.6
45–49	29	9	31.		18.5
50–60	20	8	40.		26.9
60–70	10	4	40.		
70–80	5	3	60.		

The table shows that, excepting children under 10, there is a constant increase of mortality with advancing years. On the whole the mortality of the Hamburg epidemic is less than in our series.

[The translator would suggest that American physicians are prone to report cases according to the known prevalence of a certain disease. For example many

colds and mild attacks of bronchitis have been termed "grippe" in the last few years, and probably in an epidemic of typhoid many simple cases of diarrhœa, febricula, malaria, etc., are reported to health boards as genuine typhoid, so that the aggregate mortality would tend to appear low. It is to be observed that the word "typhus," occurring throughout this article undoubtedly means *typhoid*, the qualifying adjective, *abdominalis*, being omitted.]

It is often stated that in children the mortality of typhus is low. This is not supported by our statistics. Goth also reckons the mortality of children with typhus as higher than between the ages of 10 and 25, and as high as between the ages of 30 to 35.

Liebermeister states the mortality of male patients at 12 per cent.; of women at 14.8 per cent. Murchison gives 17.68 per cent. and 18.89 per cent. respectively; H. Schultz 8.8 per cent and 9.4 per cent. On the other hand, Goth gives a higher male mortality for Kiel, and Beetz for Munich.

It was found that the prognosis became worse the later in the fever the patient entered the hospital. The duration of the fever, excluding relapses was as follows:

Up to 4	weeks, 73	per cent.
" " 5	" 16	"
" " 6	" 8	"
" " 7 or more,	3	"

The duration with children was no less than with adults. Of 154 patients under fifteen, 75 per cent. "fevered till four weeks," and 25 per cent. longer.

The time of convalescence was 20 days in 50 per cent. of all cases; 40 days in 39 per cent.; 60 days in 5.8 per cent., the last group including, almost without exception, those with sequelæ.

Including under the term recrudescence (Nachshub), a renewed rise of temperature, swelling of the spleen and rash in the period of regression, this phenomenon has been noted 63 times—3.3 per cent. H. Schultz notes it in only 1.8 per cent. of his cases. In four patients, a repetition of the recrudescence occurred; in one of them there were three in succession.

Genuine relapses occurred more frequently, 210 times, or in 12 per cent. of the cases. Authorities differ widely as to the frequency of relapses. The statistics vary from 3 per cent. to 17 per cent. in different epidemics. In the present series, there is a great difference in the annual statistics as to relapses. Relapses occurred in 108 male patients—11.8 per cent. and in 102 females—14.5 per cent. Relapses occurred relatively more often in children than in grown persons. Of 1462 adults, 179 or 12.5 per cent. had relapses; of 164 children, 31, or 19.1 per cent. Other statistics support the same conclusion. Schultz and von Ziemessen also note a more marked predisposition on the part of women. The influence of the previous typhus on the relapse is noticeable, in that the latter follows by preference a light attack of fever. Of our 210 relapses, 75 per cent. followed light or moderately severe cases. A similar percentage is given by von Ziemssen, Liebermeister, Steinthal and Goth, while H. Schultz states that relapse occurred after 236 severe cases, and after 260 cases of moderately severe or mild fever.

The beginning of the relapse varied between one and 77 days after defervescence. 24 relapses began after 1 or 2 days; 32 after 3 or 4; 20 after 5 or 6; 32 after 7 or 8; 25 after 9 or 10; 29 after 11 or 12; 12 ofter 13 or 14; 8 after 15 or 16; 5 after 17 or 18; 4 after 19 or 20; 8 after from 20 to 30 days; 3 after from 30 to 40; 1 after 77 days. Most of our relapses lasted from 6 to 20 days. 20 had a duration of five days or less; 92 of from five to ten days; 90 of from ten to twenty days; 18 of over twenty days; the longest lasted 72 days. The results of the relapse was in most instances favorable: 7 times, (not quite 3 per cent.) death occurred. According to H. Schultz, 4.1 per cent. die of the relapse.

The rash was positively present in 80.4 per cent. of all cases; doubtful in 5.6 per cent; never present in 14 per cent. The spleen was enlarged so as to be palpable in 69.4 per cent.

There was a great variation in the stools, as noted:

	Cases	Per Cent.
Continued diarrhœa occurred in	480	25.6
The movements were normal throughout in	83	4.4
Constipation persisted in	307	16.4
Diarrhœa and normal passages alternated in	144	7.7
Diarrhœa and constipation		

alternated in	550	29.3
Diarrhœa, constipation and normal passages in	62	3.3

There was a predominance of diarrhœa and constipation with two or three days without a passage and then three or four days of thin stools.

In 103 cases, 5.5 per cent. of intestinal hemorrhage were noted. Former statistics regarding hemorrhage vary between 2.5 per cent (Bülau at Hamburg) and 16.6 per cent. (Murchison at London). Griesinger gives 5.3 per cent. for Zürich, and Goth 5.9 per cent for Kiel. The first bloody stools appeared:

Between the	1st	and	5th	day	in	23	cases,
"	6th	"	10th	"	"	37	"
"	11th	"	15th	"	"	35	"
"	16th	"	20th	"	"	15	"
"	21st	"	25th	"	"	9	"
"	26th	"	30th	"	"	8	"
"	31st	"	40th	"	"	4	"
On the	55th		day	in		1	case.

In other words, three fourths of the hemorrhages began in the second week. H. Schultz states that 44.8 per cent. of his series began in the second week.

According to age. the intestinal hemorrhages are grouped as follows:

	per cent.
Up to the 15th year,	3.8
From the 16th to the 19th year,	3.5
" " 20th " " 24th "	4.2
" " 25th " " 29th "	4.5
" " 30th " " 34th "	9.4
" " 35th " " 39th "	9.
" " 40th " " 49th "	12.5
" " 50th " " 59th "	12.
" " 60th upward,	14.3

That is to say, the liability to hemorrhage increases with advancing years, except that children have the same liability as adolescents. Schultz gives 1.05 per cent. as the frequency of intestinal hemorrhages in children during the Hamburg epidemic, but Henoch puts it at 2.9 per cent. Sex appears to have no influence.

The number of bloody stools was as follows:

One in 35 patients; 2 in 24; 3 in 18; 4 to 6 in 16; 7 to 10 in 3; more than ten in 5. The highest number was 17. The mortality of typhus patients with intestinal hemorrhage amounted to 38.2 per cent., against 20.9 per cent. in Hamburg, according to Schultz. 1.8 per cent. of all patients had bloody stools before their death. Note that it is not stated that these patients owed their death to the intestinal hemorrhage; indeed, there are included in this number several who suffered an intestinal perforation, or some other serious complication.

15–2 per cent. of the women with typhus were pregnant. All were in the twenties, except one who was forty-one. No birth at term was observed. Of the 15, only one in the seventh month of pregnancy, was discharged pregnant; abortion occurred in eleven cases and premature delivery in three. Abortion occurred once in the second month of pregnancy; once in the third; twice in the fourth; three times in the fifth; four times in the sixth. The premature deliveries occurred one in the seventh month and two in the eighth; all three fœtus lived. Abortion occurred twice between the fifth and tenth days of the disease; once between the tenth and fifteenth; three times between the fifteenth and twentieth; once between the twentieth and twenty-fifth; once each at the twenty-eighth and thirtieth days. In two cases exact information is wanting

A twenty-two year old woman was admitted on the third day after delivery, and one thirty-two years old, on the eighth day. The latter succumbed and, and on autopsy, there was found, besides the characteristic typhous lesions, diphtheritic endometritis.

Of the pregnant patients, five died, three after abortion and two after premature delivery. Section showed diphtheritis of the womb. Our mortality in this class of patients amounts to 33.3 per cent., against 7.8 per cent. according to Schultz, at Hamburg. So far as we can depend on these statistics, gathered from the observation of a small number of patients, we can conclude, (1), that pregnancy is almost always interrupted by typhus; (2), that the course of the fever is more unfavorable than with other women, and (3), that the life of the fœtus is not endangered through the sickness of the mother.

Meningitis symptoms, stiff neck, violent pain in the head, etc., were noted in ten cases, all of young women. Psychoses were noted twenty times, in 1 per cent., they consisted mainly of melancholic conditions and usually appeared during the fever, rarely during the convalescence. Two

cases were noted during relapses. Several times, marked cataleptic symptoms were observed. Individual neuralgias were noticed, but not neuritis.

Pneumonia occurred 167 times, in 8.9 per cent. of all cases. The right lung was more frequently affected than the left; most of the cases were hypostatic, a single one of fibrinous nature. Death occurred in 14 per cent. of the pneumonia cases. Bronchitis was found in two-thirds of all patients. It was usually slight and of brief duration; in 3 per cent., it was severe. Pleuritis was observed 13 times; 6 as dry, 5 times as serous, and twice as suppurative forms. Eight cases were complicated with phthisis.

Intestinal perforation occurred 42 times, 2.2 per cent., including 25 cases in men and 17 in women. Age seemed to have no influence on the occurrence of perforation. Ten cases occurred between the tenth and twentieth days; thirteen between the twenty first and thirtieth; six between the thirty-first and fortieth; one each on the forty-sixth, fifty-sixth and sixty-fifth and sixty-eighth days. In twelve cases exact information is wanting, H. Schultz gives the percentage of perforative peritonitis as 1.6, .6 less than in this series.

Albuminuria is not especially frequent; namely, in 212 cases, or in 11.3 per cent. H. Schultz puts it at 12.6 per cent. for 1886, 9.4 per cent. for 1887. A number of cases entered the hospital with albumin in the urine, so that no accurate statement can be made as to the duration of the albuminuria. In 75 per cent. of the cases, albumin was first found in the third week. In 25 per cent. albuminuria first appeared in the fourth, fifth and sixth weeks. This observation coincides with statements elsewhere made, that there is no fixed time for the beginning of the albuminuria, but that it most frequently begins inside the first week of the sickness. [The obvious contradiction must be due to a misprint; probably it is meant that 75 per cent. of the cases appear in the first week. A. L. B.] In a number of cases, the albuminuria persisted only a short time or, occasionally, only traces of albumin were detectable. Excluding these cases, there were 175, 7.7 per cent., of longer duration, of which half lasted till the tenth day, the remainder till the second, third or fourth week.

Nephritis occurred 53 times, 2.8 per cent., a relatively high proportion; Schultz at Hamburg gives only .9 per cent. Age had no influence in determining nephritis, but four-fifths of all the cases were found in males. The mortality of typhus complicated with nephritis was extraordinarily high, 44.4 per cent. Schultz gives exactly 50 per cent. for Hamburg. All the cases of nephritis were of the acute hemorrhagic type. Cystitis was observed 15 times, .8 per cent. It occurred at no definite time and lasted, on the average, a week, the prognosis being good. [No statement is made as to the possible infection by catheters. A. L. B.]

A long list of other complications is appended, but they appear to be purely accidental. It is significant that hepatic abscess, which is sometimes stated to be a *sequelæ* of typhoid, was observed only once. Dysentery [typhoid infection of the colon?] was seen three times, perityphlitis four times. Nose bleed, which is usually mentioned in the symptomatology of typhoid, was noted in only 3.1 per cent. of the cases, but this may have been due to delay in reaching the hospital.

The occurrence of death according to the week of the disease, was as follows:

1st	week	6	deaths
2nd	"	37	"
3rd	"	63	"
4th	"	51	"
5th	"	22	"
6th	"	20	"
7th	"	9	"
8th	"	7	"
9th	"	5	"
10th	"	2	"
11th	"	4	"

One patient died on the ninety-seventh day after admission, after an illness at home of unknown duration. In 17 cases, the time of death was not definitely mentioned. 7 patients died in relapses. The majority of fatal issues occurred in the third and fourth weeks of the disease. H. Schultz states that 59.1 per cent. of his series died in the first two weeks of their stay in the hospital, which is in substantial agreement with the present report.

Death was due either to the severity of the infection or to complications. The former cause is responsible for 89 deaths,

37 per cent., most of which are ascribed to heart failure.

Of the complications causing death:

	Cases	Per cent.
Intestinal perforation led to death in . . .	40	16.5
Intestinal hemorrhage led to death in . . .	19	8
Croupous pneumonia led to death in . . .	24	10
Parenchymatous nephritis led to death in .	11	3.7
Pyæmia and septicæmia led to death in . .	8	3.2
Acute hemorrhagic diathesis led to death in	5	2
Acute miliary tuberculosis led to death in .	3	1.2
Abortion and premature delivery led to death in	4	1.6
Embolism of pulmonary artery led to death in	2	

Perforated pyosalpinx, fatty degeneration of the heart, general peritonitis due to perforation of the vermiform appendix by a fæcal concretion, each caused one death.

A CASE OF GLYCOSURIA.

J. M. SHAFFER, A.M., M.D., KEOKUK, IOWA.

The patient was not seen by me, and all statements are *ex parte*. The attending physician requested that the analysis be made. He says:

"There are no objective or subjective signs of diabetes; but a medical man at her recent home (Tacoma, Washington), had found sugar in the urine. No analysis presented.

"Patient is a widow; mother of five children, all living and in good health, ages from forty-nine to thirty-two years. Antecedent family history excellent. She is sixty-seven years old; weighs 175 lbs.; perhaps there has been a decrease of weight in 10 years of 25 lbs. There is no special loss of strength; good appetite; sleeps well, an afternoon nap included; bowels regular; is well so far as she knows, except an eczema with pruritis about vulvæ. About one year ago, she had an attack of sciatica which confined her to bed three months."

Just prior to the analysis she had made a journey, unattended, from the Pacific coast to the Mississippi River to visit members of her family here.

Urinalysis made April 29th shows:

Quantity voided in 24 hours preceding, 57 fluid ounces (3¾ pints, 1 f3). Color, light yellow 2 (after Vogel).
Reaction—Superacid.
Specific Gravity, 1st test—1.039.
Specific Gravity, after 8 hours—1.036.
Albumen—No trace. Tauvet's test.
Albumen—No trace. Heat.
Sugar—Loaded. Fehling's imp. copper.
Sugar—Loaded. Hylander's bismuth.
After 10 hours, specific gravity, 1.036.
After fermentation with yeast, 1.008.
Grains of sugar to f3. 28.
Sugar in 57 f3. 3¼ oz.
Solids in urine, all, 86 in 1,000.

A sample of the urine voided April 24th and left exposed to ordinary temperature has, after six days, no odor, and application of Fehling's improved copper test shows it *loaded with sugar*.

The only point made in this case is that glycosuria may exist, even to a very great extent, without presenting any of the urgent symptoms laid down as especially belonging to the disease. Moreover, that diabetes may exist and the patient or the doctor not know it. It is not needed that citation be made from THE MEDICAL AND SURGICAL REPORTER to indicate this.

In my long experience as examining surgeon of the Pension Office, two cases, where a claim for "kidney complaint" was made as the basis of a pension, are noticeable. One was a soldier from a neighboring State, had visited Colorado for his health; he never suspected diabetes; but his urine was much like above in analysis. This was subsequently verified—that is, the presence continuously of large quantities of sugar in the urine. Case lost sight of, but he may be pensioned for lumbago, or heart hypertrophy.

The other was a soldier also—his claim, deafness and rheumatism. His urine was loaded with sugar. He did not know it then; he does not know it now. He is a stout, active, splendid fellow now, and has

been. There has been no opportunity to verify or disprove the glycosuria of this case.

From these experiences it would seem that a very large amount of sugar may be present in the urine without any marked symptom or set of symptoms laid down as pathognoonmic of diabetes.

One of the old masters said, "*In omnibus morbis pectoris, ad urinam spectandum.*" Why not look to the urine in all sorts of obscure cases of illness?

COMMUNICATIONS.

ARTHRITISM AND SCIATICA.

DR. A. CLAUS.

Sciatica, also known as sciatic neuralgia and sciatic gout, is one of the most frequently observed forms of neuralgia.

It is therefore extremely interesting to discover whether the pathogenic theory which we have developed in the case of migraines and of the neuralgic manifestations of influenza, also finds here an application, or, in other words, whether the arthritic predisposition, setting aside any character of an infectious nature, is manifested in sciatica with that frequency which struck me in the study of the other neuralgias already mentioned.

One of my friends objected to me that arthritism was a conception of too vague an order, with too indistinct characteristics, to enable us to establish so precise a pathogenic relation. The usefulness of the efforts I was making to defend these ideas, which are scattered about in literature, was therefore to him not proven.

It will not be altogether useless, before attempting the study of the relations which exist more particularly between arthritism and sciatica, to consider the objections of my *confrere*.

Without entering into extended considerations upon general pathology I will say that among the physicians who nowadays make use of the word *diathesis*, some attach to it the significance of a morbid state, apparent or latent, while others whose tendency I share, simply designate under that name a general predisposition to contract a certain number of diseases which are supposed to have a common starting point.*

With Bouchard I admit but two diatheses: arthritism and scrofula, a diathesis being considered as a permanent disturbance of nutritive changes. It prepares, causes and maintains maladies varying as to symptomatic forms, anatomical location and pathological processes.

The arthritic diseases are: biliary lithiasis, gravel, obesity, the acid dyscrasia, oxaluria, diabetes, gout, rheumatic articular and subarticular affections, differing among themselves by the seat of the process, the evolution and the lesions, yet having some sort of relationship; it is the same family of diseases. The bond that unites them is the same disturbance of nutrition, a diathesis "that might be called oligotrophic, in order to indicate that nutrition transforms less matter in a given time, or oonotrophic to show the idleness of nutritive changes" (Legendre), and which Drs. Bouchard and Landouzy prefer to term bradytrophic. But custom has hitherto caused the adoption of the word arthritism, and the diseases of that family are called arthritic diseases, on account of the frequent existence among the individuals who present these diseases or in their parents of rheumatism and gout, united by the ancients under the name of arthritis.

The definition of arthritism being established, it remains to me, in order to answer my confrere's objection, to establish the frequency of the relations which are observed between neuropathic states and arthritism, and to demonstrate the usefulness of this pathogenic conception.

It is generally recognized, says Fréré*,

*Traite de Medicine Charcot, Bouchard, Brissaud, Vol. I.

* La famille nevropathique.

from whom we borrow the considerations which follow, that the neuropathic family shows close relations to the arthritic diseases, to such an extent that they are sometimes united into a mixed group, termed *neurarthritic*. One frequently meets in neurotics and in their family, rheumatism, and still more frequently gout. Baillarger had already recognized this relation of rheumatism to the neurosis in general. Thus the combination of rheumatism and hysteria is frequent; at times it is the articular affection which is the starting point of hysterical manifestations, and the two maladies may proceed side by side without influencing one another. In the same manner the association of rheumatism and epilepsy in the same individual is a very common event.

I have already noted the close bonds which unite chorea and rheumatism (Bouteille, Sée). Rheumatism, however, is not to be considered as a primordial cause of chorea; it plays, owing to its pathological relation with the neurepathic diathesis, the part of a particularly active excitant of the predisposition.

Fréré has observed a young woman who, while convalescing from articular rheumatism, was taken with chorea; an interesting point in this case was that the rheumatism, in this case, took on an hemiplegic form, while the choreic movements remained limited to the same side.

Rheumatism awakens the nervous diathesis, which shows itself by convulsive or delirious manifestations (rheumatismal mania of Burrond, Griesinger, Mesnet), according to the special predisposition of the subject. The same thing may be said of medullary localization.

It is in great part by reason of the relation of rheumatism and the neuropathic predisposition that one may account for the frequency of psychical manifestations in diseases of the heart.

As for the different forms of chronic rheumatism, their bonds with the neuropathic family are much closer, and one may expect to find them associated with a large number of neurotic manifestations. Fréré has seen hysteria tardily manifested in an arthritic woman who suffered from retraction of the palmar aponeurosia, an affection whose close connection with rheumatism is recognized.

Paralysis agitans appears to be connected with the rheumatic affections. Fréré has seen its development in an individual born of a gouty father and suffering from retraction of the palmar aponeurosis. A rheumatismal form of paralysis agitans has been described, capable of being successfully treated by antidiathetic medication.

Dr. Carpentier, who has spoken of the frequency of arthritic antecedents in the insane, has particularly insisted upon hæmorrhoids.

But it is especially in gout that nervous troubles are frequent and deserve our attention. They may be manifested as premonitory symptoms of the attack of gout or remain entirely independent of the attack, or show themselves as phenomena of the abnormal, abarticular form of gout; others, on the contrary, follow the attack of gout, and seem to be developed chiefly when the evolution of the articular affection has been disturbed, either accidentally through the sudden influence of cold or through some ill-advised intervention. The latter belong to the groups, so varied, of retroceded gout. These metastases, all the more frequent when the gout is of longer date, are the most to be feared, by their abruptness and intensity, and death may result as their consequence.

These disturbances may affect the central and peripheral nervous system in all its functions: mobility, general and special sensibility, intelligence. Charcot has called attention to the fact that all the forms of cerebral rheumatism, cephalagia, acute delirium, and even mania, may be well-nigh exactly reproduced by gout.

Among the premonitory disturbances are often met vertigo, gastralgia, irritability of the bladder, migraine, asthma, etc. Among the neuroses that are sometimes connected with gout, epilepsy must be noted. By the side of the co-existence of epilepsy and gout in the same subject, we also find the combination of both these diseases in families. Fréré has reported some interesting examples of these facts.

The uric diathesis in women may be complicated by hysterical manifestations.

Stoll and Barthez have observed cases of so-called gouty chorea. Among other accidents of retroceded gout Scudamore cites spasm of the diaphragm and of the abdominal muscles. Various authors have observed cases of gouty apoplexies and gouty aphasias; Garrod cites a case of

facial paralysis, which ceased the moment an attack of gout supervened.

Gouty mania has been observed by Whytt. Among spinal affections in the gouty we must mention a case of progressive muscular atrophy seen by Dr. Potain.

Neuralgies are very frequent in the gouty, and migraine especially so. Among visceral neuralgias, gastralgia must be especially noted.

Besides these neuralgias mention should be made of the cramps, which precede or follow attacks of gout.

The gouty nature of neuralgias is sometimes clearly shown by the happy effects of treatment: thus Begbie gives the instance of sciatica in a gouty patient, which was cured by colchicum. Personally I have insisted upon the good effects I have obtained with salophen in the treatment of migraine and of the neuralgies of influenza. I shall soon take the opportunity of showing analogous effects in the treatment of sciatica.

Among sensorial troubles attributable to gout have been cited disorders of vision. Some authors speak of gouty ophthalmias.

Nervous troubles are also very frequent in diabetics and they show the closest analogy with those observed in the gouty. Independently of the nervous manifestations of diabetes, the latter may, in the patient, coincide with characteristic nervous affections.

I can hardly insist further. I believe that this review of the subject which might be extended to all the arthritic maladies, and especially to obesity, will demonstrate to the most sceptical the narrow relations existing between the arthritic family and the neuropathic group.

We must now examine the usefulness of this pathogenic conception.

In nervous pathology especially, if one wishes to reach a rational therapeusis, truly pathogenic, we must endeavor to bring back the diverse manifestations to general causes which, once understood, alone will allow of useful and rational intervention.

Physiological therapeutics, at bottom, do not differ from systematic therapeutics. In both the notion of the disease itself is eliminated, the idea of natural evolution disappears.

The imperfection of these methods is nowhere more strikingly shown than in nervous pathologym and especially in the treatment of neuralgias.

It is not sufficient that a substance should be considered as being analgesic to justify its employment in all painful manifestations. If it be true that pain is essentially one, it were hardly scientific to forget that from the etiological and pathogenic standpoint it possesses varieties of great diversity. It sometimes is due to an anæmic state, or may arise from a congestion or an inflammatory state, etc., of the nervous fibres or cells. This is not all. These are most frequently but immediate causes, bearing an affinity to more general causes. If we do not regard the constitutional state and all the pathogenic elements, we will, notwithstanding the clearest symptomatic and physiological indications, follow a wrong road and fail to obtain the desired effect.

Those analgesics which very often are prescribed without the slightest reflection, have for the greater part a well determined elective action. If salophen, the study of which we are especially engaged in, possesses an incontestable analgesic effect, it is because it possesses primarily an antiarthritic action, arthritism being under such circumstances, one of the essential factors of the element pain.

The name sciatic gout given to sciatic neuralgia especially puts in evidence the relations existing between the arthritic diathesis and this special neuralgia. It seems to me useless to weary my readers by prolonged compliations. Rheumatism gout, diabetes and obesity are the principal etiological factors of sciatica.

If the pathogenic questions which we have advanced are true, the therapy derived from them must afford the evidence and show their usefulness and value.

It would be easy for me to justify the ideas I have just advanced by personal observations. I will limit myself, however, to the relation of five unpublished observations, which my confrere Dr. Paul Walton has been kind enough to communicate to me. I desire to thank him for his great kindness.

Observation I. M. X., 30 years, suffered from rheumatis sciatica in the left leg since four years. The attacks, which are extremely painful, usually occur in the middle of summer and in the beginning of winter. Has never shown any symp-

toms of arthritism, but his father is gouty and has rheumatism. A brother has had mild attacks of gout. The first attack occurred after a stay at the seashore; each crisis is attended by a fever of slight intensity, but the very sharp pain persists from six to ten days, during which the patient is obliged to lie down, as the sitting posture, as is commonly observed, exasperates the pain. The patient has been subjected to nearly every form of treatment: revulsives, dry cups, massage, with aconitine, phenacetine. Salicylate of soda given with veratrim has given him some relief. This winter after the occurrence of a fresh attack he was given, from the first, salophen in the dose of four grammes a day, divided in four powders. From the third powder the pain disappeared as if by enchantment. The treatment was kept up for three days during which, as the patient no longer felt the slightest painful sensation he was able to attend to all his occupations, whereas formerly he was compelled to remain nearly absolutely quiet.

Observation II. Thomassin Leon, thirty-seven years, engineer, suffered since ten years from articular rheumatism. During a long sea voyage last December, he had a very violent attack of sciatica of the left leg. Being on a sailing vessel he could only receive the most primitive sort of attention. When I saw him for the first time, he was very lame, owing to a painful retraction of the thigh upon the pelvis. Very painful shooting pains follow the whole sciatic as far as the external popliteal. He was ordered a prolonged hot bath, and five grammes of salophen a day. On the next day the pain had entirely disappeared; the lameness also had nearly gone, and the patient now dares to extend his leg. The treatment was continued for four days. After this lapse of time the patient asserts that he no longer feels the slightest pain. A few days after he went to sea again on a prolonged voyage.

Observation III. Pauline Broecke, forty-three years, suffered several years with modular rheumatism of the fingers; since eight months has a right sciatica which does not give her a moment's rest. The right limb already shows a fairly marked muscular atrophy. Because of this I first advised massage; the patient returned after a fortnight saying that the massage did her more harm than good. I must here tate the movements had been practiced by a confrere who has perhaps not mastered all the peculiarities of that specialty. As the patient insisted upon relief of her pain, I prescribed salophen in doses of five grammes daily, during four days. I also ordered prolonged hot baths. On the second day of the treatment the patient was seized with an erythematous eruption affecting the whole body; the sciatic pains had about disappeared, but reappeared on the fifth day. The patient, having attributed the eruption to the drug, has stopped taking it. Upon my advice she began taking the salophen again, but only in the dose of two grammes daily, and kept it up for six days. At this time the patient stated that she was entirely relieved. The lameness has greatly diminished but the patient still drags her leg. The cure has persisted since three months. We advised her to take salophen again at the slightest return of the trouble, but, so far, she has not had to have recourse to it.

Observation IV. Baertsoen, Adolphe, thirty years, carpenter. Presents no arthritic taint, either personal or hereditary. Suffers from a left sciatica since several weeks. The pain is nearly continuous, but is exaggerated by work, the patient, owing to the needs of his trade, being obliged to stand all day. He dates the inception of his trouble from a traumatism received more than a year ago in the gluteal region; in handling wooden beams he was knocked down by some of them and had his thigh caught under a very heavy board. Excepting for a few contusions which did not even compel a rest, the accident had no further results; but six or seven months afterward the patient daily felt, toward the end of his day's work, lancinating pains starting from the glutei and radiating as low down as the calf. The pain became more and more acute and ended by becoming constant. Revulsives and vesicants were applied, and at the same time he was given a variety of analgesics. On the days when the pain was most severe it could only be assuaged by injections of morphine.

Considering the patient's history and the fact that he had undergone a traumatism, the diagnosis of traumatic sciatica was made. This form, as is known commonly, requires some surgical treatment (stretching, etc). Notwithstanding this I tried salophen in this case, and I must say that, without having cured the pa-

tient, this drug in a daily dose of three grammes has given him a decided degree of relief for two or three days. The patient declares that on the days when he takes the medicine the pain is as well relieved as by morphine, and moreover, the amelioration lasts longer.

Observation V. Beeckman, Henry, fifty years, peddler. This man states that he suffered during his whole life with rheumatism. Wandering as he does about the country in all weathers and in all seasons, he has experienced many hardships. After the rigors of last winter, and lacking sufficient fuel in his dwelling, he has lately, besides his rheumatic pains, felt very painful sensations in the sciatic of of his left leg. I first gave him salicylate of soda in the dose of five grammes a day, as I wished to save him the expense which the relatively high prices of salophen would have entailed. In three days he returned, saying that the rheumatic pains had about disappeared, but that his thigh was no better. I then gave him salophen, and, after about a week, he stated that he was entirely cured and had not felt so well since many winters.

The very interesting observations of Dr. Walton greatly simplified my task.

Four of these patients are manifestly arthritic. The first has a decided heredity. The gouty and rheumatic father has bequeathed to one of his sons a mild form of gout and to the second a typical sciatica. If the theory I have developed is true, it is probable that the sciatic neuralgia which affects one of them will unfortunately prove but a first step in the painful road of neuropathy.

The second patient has articular rheumatism.

The third has nodular rheumatism since several years, and the fifth has had rheumatism all his life.

The relation between arthritism, represented by rheumatism and gout, and sciatic neuralgia, is here manifest; it is by no means always as evident as in these cases.

Last year I treated a patient suffering from a well-characterized hemicrania. He also had painful irradiations in the left leg, not completely localized, but quite evidently related to the sciatic nerve. The patient had very irregular digestion, with alternating diarrhœa and solid stools. At the period of onset of the neuralgic pains, his urine contained an abundant deposit of uric acid, an incompletely elaborated product showing the diathetic imperfection of nutrition. There were no other arthritic symptoms, the therapeutical results show in a most distinct manner the pathogenic relation I am considering.

All the patients treated by Dr. Walton have improved under the use of salophen. Four were cured, and one only improved. The latter had no personal or hereditary taint; his was a simple traumatic sciatica. The arthritic element was lacking, and in him salophen could not display the whole of its analgesic action. Hence we can affirm that: Naturan morborum curationes ostendunt.

I must yet insist upon one point observed by Dr. Walton. In the third observation we read that Pauline Broecke while taking salophen, in the dose of five grammes a day, showed on the second day a very marked erithema. The patient thought she saw a relation from cause to effect, and attributed the trouble to the salophen. Once rid of her sciatica she contracted a cutaneous eruption, or, in other words, one arthritic symptom was replaced by another.

Was the salophen here at fault? Dr. Vulpian* mentions several observations of cutaneous rheumatism under the form of scarlatini-form eruptions and of chronic urticaria. He also observed a case of papular erythema occurring in a patient suffering from muscular rheumatism, and Vulpian adds that it is much more common to observe papular erythema during the course of acute rheumatism than of muscular rheumatism.

In the presence of these cutaneous manifestations of rheumatism, one may well accept with reserve the accusations that might be brought against salophen. The most one might say would be that while salophen has been able to cure a painful arthritic manifestation, it has been unable to arrest the production of a fresh cutaneous arthritic phenomenon.

The importance of arthritism, which is exposed in this study, shows the important role that salophen is called to play in nervous pathology. Unsuccessful cases excepting in a few instances of defective administration, are for the most part due to an insufficient analysis of the various factors which act in painful manifesta-

*Clinique Medicale de la Charite. 1879.

tions. If salophen acts as an analgesic in the most diverse sorts of pain, one must not forget that it especially acts in those in which it is able to exert its antiarthritic action.

These therapeutic considerations will amply justify me in having dwelt so persistently upon the exposition of the relations that exist between arthritism and certain neuralgias.—*Flandre Medicale.*

CORRESPONDENCE.

IRRATIONAL TREATMENT.

EDITOR MEDICAL AND SURGICAL REPORTER:

Reading the case reported in the issue for March 28, 1895, of a patient rescued from death by aspirating the heart, makes some of us old fogies who have always kept the lancet bright, "a little" hot in the collar, when we also know, that one or more times each year for more than the third of a century, some one has given to the profession his experience of what the lancet could do for pneumonia and rheumatism.

Dr. Sloan tells us that, "from the 17th to the 22d fair progress was made," though "no great relief was got from the pains." A persistently high and varying temperature and no relief from pain may be a satisfactorily "fair progress" from the doctor's standpoint, but would the patient think so?

I thought that every observing, as well as every reading physician had learned that if salicylate of soda did not alleviate the pains of rheumatism within three days, it was useless to expect it to do so at all; and that it was equally useless to continue its use longer than seven days without an intermission, after which it may, though rarely, be resumed with benefit. Still the salicylate was increased, "and digitalis added to *strengthen* the pulse, which had been of *fair strength,* regularity and volume." There is science for you! The horse may be tired towards night, so do not spare either whip or spur in the morning.

Previous to the 24th, the symptoms, as given, strongly suggested venesection, but on that day demanded it, and the neglect of its use can be called hardly less than criminal. Had he then judiciously bled the patient, and followed that with appropriate treatment, he would not have seen that horrid picture he has pen-painted of a "livid, anxious countenance, palor of the lips, the working of the alæ nasi, the dilation of the veins of the neck and increased general restlessness."

It makes us hot. Still, we know that there are a few men who now use the lancet, who regarded it with little less than horror twenty years ago. And—and we "*hope the world do move.*"

Too many doctors get their knowledge of the actions of drugs at second hand, or as the public does its patent medicines, already prepared, put up and labeled, with "for full directions see inside of the wrapper." It is almost as easy as falling off a log, and saves an infinite amount of time and study. Had Dr. Sloan acquired a thorough knowledge of the primary and remote actions of the remedies by careful personal observation, he would not have prescribed antipyrine, salicylate of soda, nor salol, for he would have known that not a single one of the coal-tar derivatives was indicated at any stage of the—case as reported.

EDITORIAL.

INSANITY.

During the latter half of the passing century, intelligent investigations within the realm of the mind have developed results, for scientific value and practical utility far in excess of the combined speculations of preceding eras in authentic history. Medical men and psychologists have brought to bear upon all phases of insanity, the wisdom acquired from devoted study and special opportunities for observation and experience, with the result that many old theories and most old practices have been relegated to the limbo of barbarism.

Certainly a great step and most humane has been the substitution of kindness for cruelty, and of care and gentleness for harshness. Under a broader and deeper public spirit, communities have developed a keener moral sense and have learned somewhat of the care and consideration due those suffering the most awful calamity of human existence. Philanthropic and economic considerations have joined with advanced knowledge to make more humane and successful the treatment of mental maladies, although, even now, the harsh regime is not a thing altogether of the past. Too often, we yet find under a single general superintendence (incompetent to manage any), the functions of almshouse, prison and lunatic asylum, with little of intelligent distinction made in the treatment of crime and of disease.

Study is wisely directed to causes, characteristics and methods of treatment. Amelioration and improvement of both physical and mental conditions are more carefully looked after. It has been demonstrated that the malady sometimes is capable of cure.

Interest in the problems raised by these mental and moral anomalies and disorders to which human beings are subject is not confined to a few specialists. The law attaches peculiar importance to the opinions of medical men who have the opportunity of observation upon the question of mental capacity.

With respect to the powers and facul-

ties of the mind, in reality, we can know nothing. We know them only as they find expression in action.

Every physician in extensive general practice has repeated experiences in this connection, and, with his prejudices and sympathies aside—and they should be aside in the interest of the public, justice and social order—he should, of all men, be the most competent to give a just, sound judgment and one not based upon hypothetical statements, but upon actual observation and experience.

"It is a well settled practice of our courts," says an eminent jurist, "to admit the opinion of educated, practicing physicians upon subjects of medical science.

"Until quite a recent period the disease of insanity has not been made a specialty. That it is now made a special study by a small number of physicians may be a good reason for giving to their opinion greater weight, but it is not a sufficient reason for excluding the opinions of other physicians. It is well known that various classes of diseases, as those of the ear, eye, spine, skin, lungs, kidneys and abdominal troubles have become specialties, especially in our large cities, where such division of labor becomes practicable. But this fact does not render incompetent upon these subjects the testimony of other physicians, who must necessarily have less experience. The difference is in weight rather than in the competency of the testimony. The far greater number of issues as to sanity fall within the ordinary range of a physician. A physician of large experience could scarcely be found who had not been often called to consider and form an opinion upon the capacity of his patients to make wills.

"Supposing the question was as to the gradual decay of the faculties of the testator from disease or old age, one cannot but see that the opinion of an intelligent family physician, familiar with his patient's infirmities and watching them at every stage of their progress, would and should have far greater weight with a jury than that of any number of physicians who had made insanity a special study, but who were called to give an opinion upon what is always, and necessarily, an imperfect statement of the facts and symptoms. Or, if the case were one of an original defective capacity, the judgment and opinion of the old family physician would be worth more than that of the masters of the science, who can have but a fragment of his history. To put upon the stand a skillful physician (and such an one has never understood the bodies of his patients unless he has known also something of their minds and the action of one upon the other), to get from him the history of his patient, the state of his bodily health, his conversation, his conduct, traits of character in sickness and in health, and then to exclude the opinion which, as the result of all, his mind has almost insensibly and necessarily formed; and yet upon this imperfect history of this patient, to ask a perfect stranger to that patient to give his opinion of his mental condition, because he has made mental disease a special study, would be to reject the most valuable evidence, for that which, in the nature of things, must be of far less worth."

Mental disorder or incapacity, as they are called in question, either in civil or criminal procedure, must for all legal purposes be judged by the manifestations in conduct or language. Symptoms of insanity, which only physicians can perceive and which have no apparent effect upon one's ability to transact business, are not enough to vitiate one's civil contracts, nor to enfranchise from responsibility for criminal acts. Sanity being the normal condition of the mind, the presumption always is that the party was sane at the time of doing or committing the act. This presumption stands until overcome

by a preponderence of evidence in favor of insanity at the time of the act.

There can be but little doubt that juries are sometimes misled, at the expense of justice and social order, by considerations raised by the testimony of some expert or specialist with some pet metaphysical theory.

The more certainly punishment is inflicted for violation of the law and breaches of social order; the more closely and scrupulously the question of insanity is looked into when made a plea of defense; the more soberly and conscientiously juries weigh the so-called expert testimony, the less we will hear of the plea of insanity, and proportionately less crime committed.

Mischief and failure of justice often lies in a careless, perfunctory and insufficient investigation of all the phases of a case by some theorist, some one with an hypothesis to support. Courts have hesitated in grappling with a question which has been claimed to be purely medical, and medical men have failed to agree or to clear the subject of its confusions.

It is somewhat encouraging, however, that medical as well as psychological science has repudiated many old theories repugnant to the safety to society and to the truth of science as well.

The courts have advanced to recognize diminished responsibility on account of abnormal conditions. Homicide in hot blood is not murder but manslaughter; and there may be circumstances which reduce murder from the first to the second degree. All this is correct enough and responds properly enough to the better dictates of humanity, but such diminished responsibility does not enfranchise the criminal and set him loose on society, too insane to be punished for crime and too sane to be kept in restraint.

Wise laws rigidly, impartially and judiciously executed, do much to enlighten and keep enlightened the mind, conscience and moral sense of the citizen. It is within only a comparatively recent period that insanity has been admitted as an excuse for crime. The danger now is that the field of irresponsibility will become so enlarged that few criminals will be convicted. There is some risk of too great broadening of the definition of insanity, both by courts and specialists; too much indulgence of morbid philanthropic sentiment, thus increasing the number of the class who set up insanity as a defense or excuse for criminal acts.

The history of many cases spread upon our criminal records furnish a wide basis of facts for the truth of "method in madness," so called.

The Use of Vaso-Constrictors in Cardiac Disease.

Wilcox (*Med. Record*) speaks of the value of vaso-constrictors in cardiac disease. In patients in whom the cardiac disease is secondary to disease of the arteries, vaso-constrictors are not indicated. In an under-compensated heart, irrespective of whatever valvular lesion may exist, we can, by the use of these remedies, exactly regulate the amount of work which the heart is made to perform.

Obviously, by narrowing the calibre of the peripheral systemic arteries and arterioles, we may increase the obstacle to the flow of blood, and thus to a nicety regulate that which the left ventricle is called upon to do. By thus regulating the work of the left ventricle we may set up hypertrophy of muscular tissue in its walls, and in this way bring about compensation. Not only does increased blood pressure result in more blood being sent into coronary arteries, but more efficient cardiac contraction, and a more rapid circulation in the cardiac muscles, thus improving the nutrition of the heart. If it be asked in what circulatory condition digitalis finds its most useful indication, it can be said, as Fothergill long ago pointed out, that it is when the pulse is rapid, broad, and of low tension. It is here that passive congestions are most frequently found, and hemorrhages are apt to occur. Digitalis is useful because it acts as a vaso-constrictor, slows the heart, thus prolonging the systoles more perfect.

SOCIETY REPORTS.

TENNESSEE STATE MEDICAL SOCIETY.

April, 1895.

INTRA-CAPSULAR FRACTURE OF THE HIP-JOINT.

(See page 689.)

DISCUSSION.

DR. PAUL E. EVE: I have not had any experience with the Senn apparatus, but I would desire to explain a device, which I believe is in some respects at least as good and simpler. It is a device by Simpson, of New York, and is very similar to the wire corset used in spinal diseases. It is laced upon the upper two-thirds of the thigh, and also around the hips, having, if you please, a well-adjusted pad to hold the trochanter major, that has the same purpose as the screw the doctor has represented in the chalk delineation. The object of this wire dressing is to be used after the plaster of Paris, which is supposed to encase the part as far as the knee. Of course a description of it would entail an exhibit to some extent of the appliance; that, of course, we do not care to do, nor could I make a very graphic description of it upon the blackboard. But it is new, and anything that offers anything in the way of union in these very unfortunate cases certainly ought to be had recourse to.

The doctor suggested that in some cases union was had, if not bony, a ligamentous one; and in many cases an incomplete one. I cannot agree with the gentleman, or go so far as to believe that in any number of intra-capsular fractures there is no union at all. Although I take the same ground he does, that in every instance where we have these hopeless cases, instead of thinking a certain time must be passed in bed with some apparatus until the callous thrown out is sufficient to protect the spiculæ of bone and then the patient be placed in a wheel chair and allowed to eke out a miserable existence, I believe, whatever the age of the patient or wherever he is, in public or private practice, in the country or in the city, we should insist upon immobility. We should insist upon an attempt to have bony union, ligamentous union, or whatever you please to call it. I have had recently in care a lady, ninety-two years of age. She was very intelligent, and after giving her the discouraging features, for such they must be called, of treatment and showing to her that very possibly she would die, she consented to the treatment and I got a union—what kind I do not pretend to say. It may be only fibrinous or simulating a bony union and hence termed ligementous. But she is able to walk on crutches now, although ninety-two years of age. I put the plaster of Paris casing on to the knee and up to the umbilicus, and had I not, she would probably be in the grave now. Immobility should be enjoined. In too many instances, I believe, if the let-alone treatment had been other than the mere suggestion that union would not take place and death would claim the individual in six or eight months, it may be, that with any advice, perhaps only the sand-bags, we would get good results.

The doctor has very ably advocated a treatment I have followed sometimes, that is employing, in old women or men, no difference what the age, a suitable device to enjoin absolute immobility. The results cannot be harmful with a proper device, whatever it may be. We have too many forerunners to show the bad or injurious effect of such treatment, and when they are contra-indicated they can be removed and perhaps some other device used instead. An encasement is needed in every instance, or a device of some kind, whether it be the Senn, with which I have had no experience yet, or something else. But we should insist upon an active treatment in every case. We don't know what we are going to get until we try

DR. BAXTER: Closing discussion; The points I wished to call attention to and emphasize to my mind were very important. In the first place, the ordinary splint, or the ordinary routine treatment for intra and extra-capsular fractures. Intra capsular fractures with extra capsular splints, is wrong. You need something more in these cases than the treatment for extra-capsular fractures. I believe a result not usually attained could thus be obtained. It is our duty to immobolize the limb, to prevent those things which ordinarily occur in the very old from this fracture—the least of which is being entirely and completely bedridden; second, death from pneumonia; and third, fatty embolism, due to the absorption of these particles directly during the inflammatory period. I doubt whether any man who has lost an old woman from intra-capsular fracture and has failed to put her limb up, has not directly contributed to her death. This point to the aged is exceedingly dangerous, and the death comes in such a way as can be avoided by proper retention of these splints until the inflammatory period has passed by. Then if we have no union we can give them up properly.

My paper is a protest against the do-nothing policy. The dressing I have referred to is composed of iron woven into the plaster dressing, and has a screw to press against the

trochanter in the direction of the lower fragment. Senn's object was to counteract the effect of the loosening plaster after a day or two. Whether he so intended he does not affirm, but it does accomplish the retention of the fragments in cases where they were not retained before. Any case of intra-capsular fracture must have pressure in the direction of the neck, to overcome the action of the short thick muscles of the thigh.

J. S. Cain, M.D., Nashville, discussed a paper on

CROUPOUS PNEUMONIA.

DISCUSSION.

DR. THOMAS L. MADDIN: There are several points I wish the speaker had dwelt upon more exhaustively, and these points I shall present for consideration.

In the first place, I am not prepared to ignore the wisdom of past time. The question presents itself—the doctor did not discuss it, he took it for granted that the present day and age puts a negative conclusion in reference to this point, whether or not pneumonia can be aborted. When I commenced practicing medicine, a doctor would be thought a fit subject for a suit for damages if he was called to see a case of pneumonia in the early stage and didn't bleed it. I remember when I was attending lectures and listening to the distinguished Dr. Drake on this subject. Dr. Drake, on the subject of pneumonia, said: "Gentlemen, if anything can cure pneumonia it is depletion, venesection. To give you an illustration, I was called to see a gentleman for pneumonia. When I was called he was in the first stage. What was I to do? Let him sit upon the bed-side, or sitting up, bleed him to syncope. Bleed, gentlemen, to effect. And what is the effect. It is syncope. And what did syncope do? It stopped local determination to the seat of inflammation. It stopped all the pain, and if you stop all the pain, doesn't it help the patient and indicate the case if brought under the influence of the remedy?" In the '50s, nobody thought of attending a case of pneumonia in the early stage without venesection, and it was invariably to bleed to syncope; and syncope meant a stopping of determination to the seat of inflammation. If you stop local determination to the seat of disease and relieve the pain, you help your patient. Then what did they do? They gave opium, calomel and ipecac. They repeated this a few times and followed up with quinine. The patient under this treatment convalesced. You may say I am an old fogy! Well, I am not done with the bleeding yet. When Dr. Drake called to see the patient in the evening, and found the pulse full and pain present, what did he do? He bled him again to syncope and it took 20 ounces of blood to bring him to syncope. Well, is he going to get well now? Dr. Drake said he thought he would:

"I visited the patient in the morning and the fever was up again and the pulse high, and what did I do? Why, gentlemen, what could I do? I bled him again, and thought of course the patient would be convalescent when I came in the evening. But how was he in the evening? The pulse was rapid, there was difficulty of breathing, and fever, and I bled him to syncope again. And," said he, "gentlemen, if you will believe it, he died *notwithstanding*."

Gentlemen, that is the way to practice medicine. Stick to your convictions.

If the patient dosen't get well, it is not the doctor's fault. But, Dr. Drake may have been a little too absolute in his venesection.

I am going to talk along the line a little further. I am in favor during a storm, when there is danger, of throwing over-board all the freight in a ship you don't need. Therefore, I will throw overboard all the unnecessary blood in the patient, when he has plenty of it to spare; because, if you don't spare it, what will take place? It forms a great dam in the circulation of the lungs that presses the blood back. The blood cannot get through, and you drive it on through the inflamed lung. I am going to trim the ship for a clean run. What is going to take place if you don't bleed your patient, and, sometimes, even if you do. The patient, possibly, is going to die. And how is he going to die? Where is the tendency to death? If there is any stumbling block in the way, remove the stumbling block. If the man does come out crippled from the loss of blood, remember he can lose blood better than anything else. Men can lose blood better than money. It is the easiest thing to make blood, especially when you have plenty to eat. By bleeding, you enable the patient to assimilate better. Fresh blood is better than stagnant venous blood. If one lung, or a half of a lung, is involved, the entire volume of blood has to go through the lung; not through the diseased lung, for that is a stumbling block If I cannot remove the stumbling block, I will go around it rather than break my neck trying to go over it. I would bleed, in order to stop local determination and make the blood go slower, for the faster it goes the harder it runs against the stumbling block. You thereby have the oxidation increased. The danger is, if you please, edema of the brain; the danger is, if you please, over-distention of the right side of the heart; and in proportion as you have distention of any organ there occurs paresis of that organ. If the bladder is distended with urine one cannot urinate. You have to use a catheter. But you have no catheter to empty the right side of the heart when the heart is over-distended, the superior and the inferior venæ cavæ distended and the little capillaries distended. That distension reaches to the brain; and so far as that reaches you have a congestion; by a venous congestion you kill the vitality of the brain; and inasmuch, as you kill the vitality of the brain, you injure the capacity of the heart to contract. Wherever you have passive venous congestion, you have edema. Gentlemen, what is the best remedy right here? I would bleed the patient. If I have a patient whose bladder is over-filled, I can use the catheter and take the urine away. If I have venous blood doing no good but poisoning the pa-

tient and producing edema of the brain, don't you think it would be well to bleed and relieve the over-distention by opening the external jugular vein?

DR. C. HOLTZCLAW: In our section of the country, pneumonia is a comparatively rare disease. Pardon the personality, but this subject of pneumonia is quite a painful one to me. It is an unpleasant subject to me, for the first four cases I had when I entered upon the practice of medicine, were pneumonia and every one of them died promptly. There seemed to be an epidemic of pneumonia in the neighborhood. The fifth case was also one of pneumonia, but was saved from an untimely death by an accident. The patient drank 36 doses of tartar emetic, which I had ordered for the depletive effect.

Without making any remarks or comments upon the pathology of the disease, I want to present one idea as to treatment. It is an idea I got from one who was the finest physician, the most careful observer, the best therapeutist and the most successful man in the treatment of pneumonia that I ever heard of. His treatment was the administration, as soon as possible, of a teaspoonful of calomel.

Venesection has gone out of fashion, and we bleed the patients differently now. Whether the large doses of calomel (60 to 150 grains) were given to deplete, I do not know. In the second stage, of course, it would not be advisable to give it. Then other treatment is called for. But, in the early stage of pneumonia, after the administration of 60 or 100 or even 150 grains of calomel, the next morning you will be surprised to find that the pulse has gone down, the pain becomes less and the temperature lower. But this is not to be repeated. In the old bleeding process, within 12 hours the process is reported, but with calomel this does not occur. Don't take the trouble to weigh it out. There is no danger of the calomel remaining in the system. It will take care of itself. It does no harm, I can assure you. I have never had a death from pneumonia under this treatment, and you will always find it extremely satisfactory.

DR. W. D. HAGGARD, Nashville: I wish to endorse what has been said as to the ability of the physician to abort pneumonia. However, I believe it can be done more effectually than in the way Dr. Maddin has outlined. Given a man such as he described—a stout, healthy man, with a full, bounding, quick pulse, pain and hyperexia, then bleeding to syncope is a most valuable part of treatment. I believe there is nothing we have ever had comparable to bleeding under such circumstances. I believe it is unfortunate for the world that venesection has virtually passed away. I believe it would be well if it were restored to its former position in the practice of medicine. But, after the first venesection I could not repeat it, as did Dr. Drake, or as did Dr. Bartholow when I was a student, because I believe we have a better remedy in the heart sedatives. You may commence with the heart sedatives after you have once depleted the system by withdrawing twenty ounces of blood, or you need not use the blood-letting at all, but commence at once with the heart sedatives. I feel confident, in this way, pneumonia has been aborted. The patient should be brought thoroughly under the heart sedative, whether in the form of a venesection or in the form of the tincture of aconite or tincture of veratrim viride. What you want is to reduce the pulsation of the heart; you want to relieve the great blood-pressure.

I should certainly prefer the heart sedatives to the frequent repetition of blood-letting, and I put myself upon record as very much averse to the practice referred to by the distinguished gentleman last upon the floor. That practice would not be endorsed at this time.

I arose to put myself upon record as believing pneumonia can be, has been and will be aborted; and the better we understand the pathology and therapy of the disease, the better we will be able to abort it. This is best done in the first stage.

DR. J. A. WITHERSPOON, Colnmbia:—Pneumonia, being one of the most common diseases we are called upon to treat, and one we more frequently disagree upon, possibly, than any other, should attract attention in any medical body. I must disagree with most of the gentlemen. I don't believe that the ideas, so prevalent here to-day, in the treatment of pneumonia, should be exercised in any one case. Pneumonia is a disease that is liable to attack people of different constitutions, and the patient should be treated more than the disease. I do not think it is wise for us to outline or map out any line of treatment in pnenmonia.

I agree with Dr. Maddiu's idea of venesection, but I should limit it to a few cases—the plethoric—those full of blood, where I believe it may be applicable. But I don't believe that in pneumonia, blood-letting for pain in necessary. I do not believe pain is a symptom, especially of croupous pneumonia. It is an indication of a complication of that disease.

Further, I would differ from Dr. Cain. I don't believe bronchial breathing is a symptom of the first stage in pneumonia, but that it is a symptom of red hepatization, or the second stage. I understood the doctor to outline certain pathological findings, how they were produced and why they produced certain symptoms. I believe he claims the inflammation does not produce the exudation. I believe the inflammation, or the inviting of blood to that part and the production of a hyperæmia of that lobe, is the result of the specific cause of pneumonia itself, and it is this irritation which invites the blood to the part, produces a dilatation of the capillaries and hyperæmia and the accumulation of fibrinous material. We have, in the first stage, a stage of engorgement, as the doctor said. What does the engorgement mean? It means the blood-vessels are filled with blood. Next is the stage of congestion, when, by the diapedesis of the serum of the blood, the fibrinogen being acted upon by the fibrin ferment forms the exudate that takes place in the air vesicles, and forms the exuda-

tion that is to follow. Now, until that exudation and until those air-vesicles are filled, you will still have a roughness, or vesicular breathing. But when that is closed, then through the solidified lung you will hear tubal breathing. I claim the tubal breathing is found in the second stage. What is the crepitant rale due to? The Doctor explained that it was due to a sticky exudate formed, an inflammation of the part, and the pulling of it apart, as it were. If you have a pulling apart of the vesicles, you have a vesicular and not a tubal breathing. I grant you the tubular breathing is symptomatic, but I believe only of the second stage.

I believe in the use of digitalis. It seems to me it would be extremely bad policy for us to use a drug that acts upon the heart only by stimulating the inhibitory nerve center, which, by laying its inhibitory hand upon the heart shortens its beat and carries more blood to the vascular system in the lung. Therefore, I do not believe digitalis is applicable to the first stage, but it is applicable to the second stage, especially because we have the breaking down of the exudation. It is then you want a slow, deliberate beat to throw the blood and open up the vascular channels that have been closed. Then is the time, and the only time in my humble opinion, we can afford to use digitalis in the treatment of pneumonia.

As to the red hepatization, or the third stage. I cannot understand how it is possible after the exudation is produced, for us to cut it short. The stage of red hepatization does not last long, at any rate, but passes to the gray hepatization very rapidly. It is the hurrying of this stage we desire. It is in this stage I have gotten my best results from the use of the blister. I use the digitalis and strychnia to stimulate the heart.

One other question in the treatment of this disease. Dr. Cain recommends the use of syrup of ipecac and various remedies at this stage to assist in getting rid of this exudation. To give ipecac and such remedies in the third stage, when there is need of strengthening of the action of the heart, of perfection of the action of the stomach of thorough assimilation of nourishment, in my opinion, is not well directed treatment. One remedy, which has a bad effect upon the stomach, however, in some cases, is the iodide of potash. I like the iodide of potash, I like, in the first stage, the cotton jacket over the chest and then, if I have tardy resolution, I bring to my assistance the blister. In the condition of heart clot, I have been struck with the propriety of a suggestion by one of our Southern men, of intravenous injections of salt solution just as you treat shock. This is used by a physician in Birmingham. When the pulse has become very feeble, the nose open, the eyes sunken and the cheeks prominent, he uses a 2 per cent. solution of salt, and the pulse rises almost as if by magic. I have never tried it, but I was struck very favorably by the method. With that, and believing that each case should be treated on its own merit and according to the conditions found in the case, under no routine. I consider we have the best means of meeting and combatting this disease.

Dr. G. A. Baxter, Chattanooga: Concerning the danger of heart-clot in this disease. Dr. Cunningham, of Chattanooga, reported 92 dissections of croupous pneumonia, and in about 50 he found, and exhibited at the Tri-State Medical Society, heart-clots.

Dr. Crook, Jackson: I can endorse what has been said about pneumonia being aborted. It is plain to me that any acute inflammatory affection can be held in check if you hold down the temperature of the body.

Another thing the essayist did not refer to, although he went over almost the entire field: He did not speak of the use of alcohol; nor has that been mentioned. I have frequently, as Dr. Cain said, changed my opinion, but it does seem to me we can get along better without alcohol than with it. My mainstays are digitalis, strychnia and quinine.

Dr. S. W. Sanford, Union City: I wish to relate an experience. I never saw a case more thorpughly aborted, than one which took thirty drops of croton oil; and he didn't die, either. Another point. Dr. Cain in enumerating the antipyretics, I believe, overlooked the one that in my opinion is the best of all, that is Salicylate of ammonia. With it you get all the antipyretic effect desirable without the bad effects so often experienced from the coal-tar remedies.

Dr. Deering J. Roberts, Nashville: Much has been said about venesection, but I think, with the ideas I have of pneumonia, the proper views of venesection have not been taken. The gentlemen who advocate it look forward to it just as was done forty years ago to bleed some, to bleed again; others would limit it only to full, plethoric individuals.

It is not so much the individual as it is the time when you perform venesection. If you can bleed the patient in the stage of hepatization, the patient has already bled himself into the cavities of the lnng. A lobe of the lung will hold a pint to a pint-and-a-half of blood. Therefore, a solidified lobe will contain, perhaps, a pint or a pint-and-a-half of blood. Later in the stage, a little bleeding may take some off the lobe, but one must be cautious in late bleedings, and they must be limited in amount. Hepatization commences at one spot and gradually extends. You have to watch it closely; and you may not be called until solidification has taken place. You can then only, at some future day, take some off the lung. I care not how old or young, how weak or strong the individual may be, if you can diagnose the disease in the stage of hyperæmia before there is any great solidification, bleed according to the amount of vascular supply in the individual and you will do more towards arresting the disease than by any remedies we have. The pendulum swung too far when bleeding was entirely stopped. I cannot but think, from my experience and observation and from the observations of others with more experience than myself, than in the past thirty or forty years many lives have been lost from pneumonia

because we have not used the time-honored lancet.

A gentleman who has often raised his voice and wielded his pen in favor of this remedy, Samuel D. Gross, read before the American Medical Association, an excellent article, on "A Lost Art in Medicine." He laid stress upon the time the lancet should be used. You must bleed your patient before he has bled himself.

In the early stage of pneumonia, or the state of hyperæmia, what sounds we have? Before dullness or crepitant rales come on, there is increased resonance with absence of the ordinary murmur. In the stage of hyperæmia, the blood vessels have distended and made tense the alveoli of the lung over a limited area. In other words, you have exudation in lower lobe. I have noticed this repeatedly. It commences usually below or in the middle lobe, but may be in the upper lobe, and when, perhaps a half of the lung has been lost, it is too late to bleed except you find the right heart struggling with too great a load; then take out blood until the vitality of the patient, with the other remedies, will eliminate the material from the lung.

I wish to endorse what has been said as to iodide of potash. Some 18 or 19 years ago, Dr. Flint advised the use of the iodide of potash, but did not give any reasons. I tried it in large doses, and to my surprise the bronchial tubes cleared up almost as if by magic. Since then I have been using it in pneumonia. Instead of waiting day after day using stimulating expectorants to get rid of the refuse matter, I put the patients upon full doses of the iodide of potash, five to ten grains, three or four hours apart. And what is the result? The lungs become cleared up. It acts as a resolvent. The material is absorbed. I regard it as of invaluable use in this disease. Strychnia and digitalis I reserve for use in the later stage of protracted cases, for maintaining strength from vigorous cardiac systole in preference to the frequent, rapid systolic movement that wears the heart out. As for blisters, I rarely use them. Warm fomentations to the chest, a hot bran bag, hot poultices made slightly stimulating by mustard, if you please, and capsicum, are of use over the side involved, and have an advantage in the relief of pain through the anodyne influence of the heat. In protracted and stubborn cases, where in spite of all remedies the lung would remain solid or approach to purulent exudation. I have occasionally seen valuable results follow the use of a large blister. Where I begin to dread that, or apprehend it is close at hand from the duration of red hepatization, I resort to the full large blister, getting rid of it as quickly as possible afterward, with very satisfactory results. I know a number of gentlemen, fairly successful in the treatment of pneumonia, who blister at once. I do not like to blister at once, because it keeps me from interpreting what is going on.

Dr. N. C. Newman, Normandy: The statement by the gentleman who has just taken his seat, that it is not necessary to bleed a patient who has already bled himself, is not according to my view. In a plethoric individual, with the lung solidified, you are very likely to have edema of the brain, and for that reason bleeding is indicated. If you have edema of the brain, in all probability you will not be able to overcome it with anything short of bleeding.

In reference to digitalis. Some of the gentlemen prefer strychnia and some object to the use of digitalis. One of the great sources of death in pneumonia is heart failure. Now, in the later stages, when the heart is enfeebled, digitalis slows the action of the heart, strengthens its systolic force, gives greater time between the beats of the heart, allows the ventricles to fill better, stretches the vital India rubber of the aorta and feeds the heart through the coronary arteries, which are the only arteries in the heart whose beat is synchronous with the beat of the heart. As the heart is strong in its force, having been properly fed after the use of digitalis, it is better able to do its work. So we give digitalis not only for its effect as a nerve stimulant, but also for its nutrient effect, especially its secondary effect. If you have depleted your patient by venesection in the beginning and are afraid of heart failure, you must enjoin the recumbent posture and give digitalis in small doses, very frequently repeated, for the secondary and nutrient effect.

Dr. O. C. Omohundro, Nashville: I prefer the iodide of ammonia to the iodide of potash, and think it fills the indication better. A remedy more recently suggested is simple bicarbonate of soda. Those are the only remedies I can think of besides those that have been already mentioned.

Dr. T. J. Happel, Trenton: There is one feature of this paper upon which I want to congratulate Dr. Cain, namely, the fact that he does not accuse the wonderful microbes of producing this wonderful disease. It is about the only disease in the discussion of which, in the Tennessee State Medical Society, I have not heard attributed to the microbes. It is true the essayist said one of the theories is it may be due to a microbe. But I want to congratulate him. I think the microbe is sent there to clear out and not to produce the disease. Food is furnished in the lung where it grows and the microbe is intended in this case, not as a disease-producing or disease-causing agent, but as a simple curative agent. It helps eliminate the material from the lung. Dr. Witherspoon struck a feature I wish to emphasize, too. That is, it is the patient and not the disease we have to deal with. I have always believed that if I find a case of pneumonia suitable for bleeding, I shall bleed it. I have practiced medicine in Tennessee for quite a while, but have not as yet found that case. However, if I do, I will bleed it and bleed it freely.

I wish to mention a case I had been treating for pneumonia and dismissed as relieved. He took a severe cold and developed a double pneumonia, as I believed from the history. When I was called I found the vessel by the side of the bed half full of blood, which they

said was half of what the patient had expectorated that night. The lung was greatly cleared up by the bleeding. The point I wish to make is that we do not see these patients in time to bleed them. We ordinarily see them in the second stage, after the time for bleeding has passed.

We can abort the disease, as suggested by a previous speaker, by the use of veratrim viride. I do not rgree with Dr. Holtzclaw as to the value of large doses of calomel. We rarely see cases of pneumonia in the first stage and don't get too much for the patient. In the stage of hepatization there is no time for bleeding. Nature will do the work there very well. You may have to control the temperature. In the third stage, although a large number of cases will get well without treatment, if treatment is demanded medicinally, we need digitalis and strychnia. I agree with the preference for iodide of ammonia to the iodide of potassium. I do not believe in expectorants—squills, spices, sanguinaria and things of that kind—and I only give them where there is a prejudice in the neighborhood, and then I tell I am not in favor of them. If you keep your patient in proper condition the material will be taken up by the absorbents. It is not intended the material shall be thrown off by expectoration. Let your patients alone; don't disturb your patient's stomach; tone him up. If the lung does not clear up rapidly, I would then, and then only, apply the blister. I would keep the surface reddened, preferably by turpentine steepes, or by the use of the mustard plaster. These I use, protecting the chest, of course, from changes in temperature when removing the application.

DR. J. D. PLUNKET, Nashville: The fact that a disease has so many names as croupous, fibro or lobar-pneumonia, tells us the cause of that disease was unknown to the earlier clinicians and pathologists; but I believe when I say croupous pneumonia is a microbic disease I voice the ideas of most bacteriologists.
Finding the specific cause of the disease; cultivating it through several generations; then inoculating animals and producing the disease, typical in every manifestation. I think if this exists in some 95 or 96 per cent., it has great weight in determining the cause of the disease. But, in respect to the older school—those who have laid great stress on the influence of cold producing this particular kind of pneumonia—it does seem there might be something in the idea. Whether or not there is, remains for the future to reveal.
hen this disease attacks one individual in a family and then another and another member, until the entire household is prostrated with the disease, independent of age, condition of life, hygiene, and everything taken into consideration it confirms or strengthens the belief that croupous pneumonia is of a microbic or specific origin.

As to the treatment of pneumonia I have but a few words: When anybody becomes a routinist in the treatment of any disease, whether it is croupous pneumonia or any other, I believe that medicine is not his harvest field. You take a child prostrated with acute inflammation and the whole of one side below par; you don't think of bleeding an individual like that. You will not apply a blister to a very young child; I don't do it myself. But here is a disease where I believe every case is a law unto itself. You have an individual with a strong acting heart, bounding pulse, flushed face, a little pleurisy and perhaps a little pain which annoys him. Bleed him and he is relieved from the inconvenience which he suffered.

It has been said that pneumonia is the great enemy of old age. How often are we called to see an old person, presenting no well-marked symptoms of pneumonia, with a little rise of fever, say to 101½° or 102° accelerated respiration, may be; no cough, pulse possibly a little accelerated? The patient grows rapidly worse, sinks, dies and at the post-mortem find a croupous pneumonia, involving either the greater part of one lung or one lobe or the croupous process attacking isolated spots in both lungs. If we take the disease in the adult, say eighteen to thirty years of age, we will see the typical manifestations of fibrous-pneumonia. But take it in children, two to four or five years old, as we have seen it many times, and the little child, apparently perfectly well, will go in and tell his parent, "I am sick"; he develops a little cough, butdoes not expectorate; there is accelerated pulse and respiration, and a high temperature. We should examine the condition of the lungs, as to the presence or absence of croupous pneumonia, because we often find it in children without the usual signs of the disease.

DR. J. S. NOWLIN, Shelbyville: There is a discrepancy in the theory of the gentlemen who hold that pneumonia is caused by a microbe, yet advise a line of antiphlogistic treatment. Now it is either true that pneumonia is an inflammatory disease, from the result of inflammation, or it is the result of a specific disease. If it is the result of a specific disease, it should have specific treatment, such as is germicidal and will remove the cause.

Dr. W. K. SHEDDAN, Williamsport. The subject has been discussed seemingly with the idea that an inflammatory condition could not be due to a micro-organism. I believe all inflammatory conditions are due to micro organisms. I am fully satisfied, from my observations, it is due to a micro-organism, and that the micro-organism has been very well described by Dr. Sternberg. It has been said that edema of the brain is due to passive congestion. I think the cerebral conditions, said to be due to edema, more are due to the action of the toxines than to any edema. I believe the irritative action of the toxines will explain this condition fully. One proof it is due to some germ or to something constitutional, is the fact we frequently have the most marked constitutional trouble as complications.

I notice in connection with the discussion of this subject the frequency with which gentlemen have alluded to the ability to abort. I wish to be recorded as believing that no case of true croupous pneumonia on

God's earth was ever aborted by any line of treatment. The fact we have no specific to destroy the bacillus of pneumonia is not a proof it is not a germ disease. We have no specific to destroy the bacillus of tuberculosis; we have no specific to destroy the bacillus of anthrax; we have no specifics to destroy a number of these bacilli, but that is no objection to the germ theory. When we find something to eradicate the bacillus of pneumonia, then they may talk of aborting; but it is useless to talk of aborting by venesection or anything of that kind. I would certainly, in any stage of this disease, most assuredly condemn cardiac sedatives. As I understand Dr. Cain's position, he regards the red hepatization as part of the first stage, and therefore he would find the condition he stated.

The use of ipecac has been objected to, but the gentleman immediately afterward recommended a blister, which would irritate the already worn-out nervous system, and for what? I have never been able to see any indication in this disease, in any stage, for the use of blisters. I think the comment upon Dr. Cain's ipecac much out of place if one is going to use blisters.

I treat every case according to the indications of the individual case.

Several years ago I was very much impressed by the idea of the use of cold compresses over the area of the lung. Two years ago I had the fortune to see a case of pneumonia in the early stage, that of hyperæmia, and I enveloped it in ice bags. My brother, following my suggestion, did the same thing with a number of cases. In some twenty cases we used the ice bags with absolutely no mortality.

DR. W. A. H. COOP, Nashville: I believe, reasoning from analogy, pneumonia is caused by some germ. I believe the mental depression and all that is created by the toxines, and the influence upon the heart probably has the same cause. The same cause may be an explanation for the presence of the leucocytes.

DR. J. S. CAIN (closing discussion): We have had every variety of treatment suggested, from full doses of calomel, thirty drops of croton oil, venesection, to very little of anything and not much of that. So you see there is a great variety of opinion about this disease, and it it a disease about which we, as a profession, are not agreed.

I did not undertake to discuss the microbic origin of pneumonia, but simply alluded to it and said I did not have time to discuss it.

A deal has been said about aborting the disease, blood-letting especially. I have nothing to add to what I said in the paper about blood-letting. I believe there are some few cases in which blood-letting is the thing to do, but I believe tartar emetic and blood-letting are not indicated in a great many cases. A great many patients when bled, even when blood-letting is not indicated, will get well, but I believe that is not rational treatment in one case out of a hundred. Like Dr. Happel, the case for blood-letting has not come to me for a number of years. Yet I would not disapprove of it in proper cases. Dr. Witherspoon took me to task about a physical sign. I said bronchial respiration is one of the first signs of bronchial or croupous pneumonia. I adhere to the opinion. Just so soon as the parts become engorged and the tissue loses its porosity it becomes a better conductor of sound and conveys to the ear of the diagnostician the sound of the air passing in and out of the tubes. When solidified it is a still better conductor. I find bronchial respiration before I find bronchial crepitation. It is the first sound.

I am sorry more was not said about the use of digitalis in the early stages of croupous pneumonia. I said in my paper I could not explain the reason why it should be used, because it seems to be contra-indicated, since it is a heart stimulant, and we want to use remedies to lower the heart's action. However, it not only stimulates the vaso-motor system, but also the inhibitory; and while it propels the blood with more force, it creates a space on the other side for the blood; keeps pure blood moving through the lungs and prevents stasis. I do not know any other explanation for it, but I believe it is one of the best remedies in the early stages of croupous pneumonia.

PERISCOPE.

IN CHARGE OF WM. E. PARKE, A.M., M.D.

MEDICINE.

A New Method of Making Palatable and Digestible Milk.

Dr. Robert T. Edes, of Boston, gives a valuable way of preparing milk where other methods have not proved useful:

A pint of milk is gently warmed. Into it is dropped, very slowly and with constant stirring, about twenty minims of the dilute hydrochloric acid of the United States Pharmacopœia. The milk should be stirred until it cools. In this way a very fine flocculent coagulum is produced, floating in the whey, which is easily accessible to the digestive secretions, while the whole fluid has lost somewhat of the flat and cloying taste which makes it unacceptable to so many. It will be noticed that milk prepared in this way differs from the various "wheys" in the highly important particular that the casein is retained and used, instead of being separated out as a distinct product, while it avoids the bitterness of pancreatinized milk.—*Boston Med. and Surg. Jour.*

SURGERY.

Effects of Modern Rifle Wounds.

The London correspondent of the *American Practitioner and News* writes that Prof. Victor Horsley has given an interesting lecture on the "Effects of Modern Rifles." First, Dr. Horsley showed some photographs of bullets in flight, demonstrating that in front of every bullet is a parabolic curve of compressed air, while behind it there are a series of little eddies of air rushing into the vacuum created by the flight of the missile. A tin canister was taken, and a ten-grain bullet having a velocity of 3,800 feet per second fired through it. There were two small holes in the canister. Then the lecturer filled a canister with some wet, soft substance, put on a lid and fired again. The lid of the canister flew off, showing that the bullet in its passage caused the hydrodynamic effect to be communicated right to the outside particles. An empty skull was then fired through, two small holes being the result; then a skull filled with water was treated in the same manner; this time the skull splintered and gaped. Dr. Horsley said these demonstrations showed that when a bullet is fired through a brain the substance is forced in all directions with violence and great pressure against the skull. Prof. Horsley has demonstrated by experiment that after the shock of a bullet through the brain the heart will begin again irregularly, spasmodically, but still it will begin again. The lungs will not. In his experiments the action of the heart and lungs of an animal were indicated by a system of pneumatic tubes and levers upon a chart. An animal under ether had a shot fired at it so as to glance off the skull. Both lungs and heart continued working unchanged. Then a shot was fired through the brain. This time the heart continued to go on irregularly, but the breathing ceased. The net result of these and other experiments was to show that, provided the action of the lungs could be restored, an animal might be shot through the brain and live. The brain with a passage forced through it is still pressing heavily against the sides of a skull. This must be relieved by trephining, and the conclusion arrived at by the professor is, that if a man were shot through the head and were treated first as if he were a drowned person until such time as trephining could be performed, his life might be saved.

BACTERIOLOGY.

The Transmission of Tuberculosis by a Brass Horn.

Dr. Addison S. Thayer, in the *Journal of Medicine and Science*, reports the cases of three young men, whose family history was good and who were themselves physically sound, who became infected with tuberculosis by using, as members of a brass band, a second-hand horn hired from a dealer. The possibility of tubercle bacilli being deposited in the convolutions of a horn to the danger of subsequent players cannot be denied. The three users of the horn in question were the only members of the band who did use it. Two of them are now in Colorado and one in Southern Pines under climatic treatment for tuberculosis. To make the chain of evidence complete it is only necessary to take the horn to pieces and find tubercle bacilli in the dried spittle in its convolutions and joints.

OBSTETRICS.

Pregnancy After Ligation of the Fallopian Tubes.

At the December meeting of the Glasgow Chirurgical Society, Drs. Murdoch Cameron and R. M. Buchanan, made a report upon the clinical history and post mortem examination of a case where pregnancy occurred after ligation of the tubes.

Two years before this conception the woman had been delivered by Cæsarian section of a healthy mature child. Dr. Cameron tied the tubes at that time. Four days after the last Cæsarian section the patient, who was a dwarf and rachitic, died of peritonitis, and the post mortem examination was made by Dr. Buchanan.

The right fallopian tube showed the constricted portion without any trace of lumen, while the left was pervious throughout, although the canal was much narrowed and the plications atrophied and irregular.

Dr. Cameron said that this was the first case in which he had ever found pregnancy to occur after ligature of the tube, and attributed the fact in this instance to his failure to tie the ligature sufficiently tight. He thought it would be especially dangerous to remove the ovaries at such a time when the veins were enlarged and sepsis might so easily be introduced, and therefore was accustomed to rely upon ligation of the tubes. In his last case of Cæsarian operation he had taken the precaution of putting on a double ligature, cutting between, and making such a separation that he did not think union could possibly take place.

Dr. Hector Cameron said he would not have thought *a priori* that a silk ligature would have permanently obliterated the fallopian tube. There was no analogy between that and an artery. It was fashionable nowadays, when tying an artery, not to try to sever the inner and middle coats; but he himself always did try to do so, and when that was done the reparatory process which followed was almost certain to obliterate the artery at that point. There was no analogy to this in the case of the fallopian tube, and it had always struck him that the method which Dr. Murdoch Cameron had described for his last case (double ligature and dividing between) was the right one and ought to ensure success.

The Cold Bath in Puerperal Septicemia.

Mace (*Archives de Tocol et de Gynec.*) strongly advocates this treatment. He has

collected seventy-four cases. They include seven deaths—three from peritonitis, one from pyemia, one from exhaustion after a long shoulder-presentation labor, and two from severity of the infection; the baths were given with too much timidity. The cold bath is contra indicated when peritonitis, phlegmon of the broad ligaments, or phlegmasia dolens exists. It has proved successful when grave maladies, such as measles, erysipelas, eclampsia, or bronchitis have complicated the puerperal infection. The obstetrician must not delay treatment when high temperature and general constitutional disturbance have set in. First of all, he must make sure that the uterus is free from products of conception. Then, should the temperature rise over 101°, the bath must be used. It is often of value when the temperature is low, the patient already suffering from headache and hot skin. The bath should be a little over 75° F. as a rule. Mace insists that it is right to leave the patient in till she shivers, especially when hyperpyrexia is the most marked symptom. In other respects the same precautions are needed as in typhoid fever. Subcutaneous injections of caffeine or sparteine should be given before the bath when the symptoms are severe, so as to counteract the tendency to syncope.

ARMY AND NAVY.

CHANGES IN THE U. S. MARINE HOSPITAL SERVICE FOR THE FIFTEEN DAYS ENDING APRIL 30, 1895.

Fessenden, C. S. D., Surgeon; detailed for duty on Board for Examination of Officers Revenue Cutter Service, April 17, 1895.

Hamilton, J. B., Surgeon; granted leave of absence for 12 days, April 20, 1895.

Stoner, G. W., Surgeon; detailed to represent service at meeting American Medical Association, April 25, 1895.

Mead, F. W., Surgeon; detailed as Chairman Board for Physical Examination Officers Revenue Cutter Service, April 17, 1895.

Banks, C. E., Passed Assistant Surgeon; when relieved to report at bureau for duty as Chief of Purveying Division, April 24, 1895; granted leave of absence for 14 days, April 29, 1895.

Williams, L. L., Passed Assistant Surgeon; detailed for duty on Board for Examination of Officers Revenue Cutter Service, April 17, 1895.

McIntosh, W. P., Passed Assistant Surgeon; detailed for duty on Board for Examination of Officers Revenue Cutter Service, April 17, 1895.

Kinyoun, J. J., Passed Assistant Surgeon; detailed to represent Service at meeting American Medical Association, April 25, 1895.

Woodward, R. M., Passed Assistant Surgeon; to proceed to Ashtabula, Ohio, as Inspector, April 19, 1895.

Wertenbaker, C. P., Passed Assistant Surgeon; granted leave of absence for 10 days, April 16, 1895

Brown, B. W., Passed Assistant Surgeon; detailed as Recorder Board for Physical Examination Officers Revenue Cutter Service, April 17, 1895; granted leave of absence for 20 days, April 23, 1895.

Stewart, W. J. S, Assistant Surgeon; to rejoin Station at Washington, D. C., April 20, 1895.

Prochazka, Emil, Assistant Surgeon; to proceed to Evansville, Ind., for temporary duty, April 29, 1895.

Thomas, A. R., Assistant Surgeon; granted leave of absence, April 17, 1895.

NEWS AND MISCELLANY.

Deer Park on the Crest of the Alleghenies.

To those contemplating a trip to the mountains in search of health and pleasure, Deer Park, on the crest of the Allegheny mountains, 3,000 feet above the sea level, offers such varied attractions as a delightful atmosphere during both day and night, pure water, smooth, winding roads through the mountains and valleys, and the most picturesque scenery in the Allegheny range. The hotel is equipped with all adjuncts conducive to the entertainment, pleasure and comfort of its guests.

The surrounding grounds, as well as the hotel, are lighted with electricity. Six miles distant, on the same mountain summit, is Oakland, the twin resort of Deer Park, and equally as well equipped for the entertainment and accommodations of its patrons. Both hotels are upon the main line of the Baltimore and Ohio Railroad, have the advantages of its splendid Vestibuled Limited Express trains between the East and West. Season excursion tickets, good for return passage until October 31, will be placed on sale at greatly reduced rates at all principal ticket offices throughout the country. One way tickets, reading from St. Louis, Louisville, Cincinnati, Columbus, Chicago, and any point on the B. & O. system to Washington, Baltimore, Philadelphia or New York, or vice versa, are good to stop off at either Deer Park, Mountain Lake Park or Oakland, and the time limit will be extended by agents at either resort upon application, to recover the period of the holder's visit

The season at these popular resorts commences June 22d.

For full information as to hotel rates, rooms, etc., address George D. DeShields, Manager, Deer Park, or Oakland, Garrett County, Md.

ORIGINAL ARTICLES.

PUERPERAL ECLAMPSIA.

S. T. HARDISON, M.D., Lewisburg, Tenn.

In view of the oldness of the subject, the general knowledge with reference to it, the much that has been written about it, and the experience that most have had with it, I am sure whatever encounter you may have had with puerperal eclampsia has made an indelible impression upon your mind. No medical man ever forgets his experience with this disease; if disease we may call it, for I believe it is agreed that is only an expression of some existing pathological condition and not a disease *per se*. Nor is it found to be uniformly present when the known conditions that produce it are present; therefore it is exceedingly uncertain in its manifestations; coming when least expected, and failing to come when the most experienced attendants are led to foretell its advent from the symptoms present. But when it does come it is the one time in a doctor's life that he needs a clear head, a brave heart and a skilled hand, for he may expect every one else to be demoralized. The invasion is so sudden, so unseasonable, when the hopeful, expectant mother is buoyed up with the promise that in travail she shall be spared; the friends and attendants are cheerful, when without warning, all is changed to danger, gloom and sadness.

Eclampsia occurs most frequently during parturition; sometimes months before, and more rarely immediately after delivery. There is nothing distinctively characteristic or peculiar about the convulsions to distinguish them from other convulsions; indeed all convulsions are very similar, whatever the cause, whether produced by dentition or hydrophobia. So if it were not for the puerperal state, we might hesitate to decide whether we had epilepsy or tetanus. If the fits are repeated, the intermissions are of uniform length. I shall not further describe the symptoms; when once seen they will always be remembered and readily recognized.

Much has been written by our most learned authors in regard to the cause or causes. But their knowledge and the concensus of opinion has not been very emphatic nor conclusive. Many pathological conditions have been so frequently associated with it as to be chargeable with being causative factors. But not being able always to find these conditions present, we are forced to the conclusion that it is produced by a multiplicity of causes.

Primarily, I think we must have that condition of the nervous system known as convulsibility, the cause of which condition I do not know, but that it exists, all agree. By which it is understood that while there is no great departure from a healthy condition, at least nothing detectable, the least untoward circumstance, either mental or physical, will cause an explosion of nervous function, resulting in

convulsion; and one such manifestation seems to so impress the nervous system as to invite a repetition.

It is also universally agreed that faulty elimination from any of the excretory organs is a prolific source from which convulsions are induced. Possibly the kidneys are more generally at fault than any other eliminating channel, even if they be not organically involved. Probably we always have more or less irritation of the urinary organs in pregnancy. If we do not have mechanical irritation, we have sympathetic irritability which results in faulty and insufficient elimination and sooner or later produces a septic condition of the blood. As to whether this sympathethic or mechanical irritation is sufficient to account for the non-performance of the kidney, thereby producing sepsis, or whether there is something in utero-gestation itself as a physiological process which results in vitiating the blood, is a question that has been raised but has not been settled.

When the kidney is organically diseased, we know it is an important factor in the production of convulsions. But we must not forget that patients with chronic organic kidney disease in advance stages, do pass through utero-gestation and the process of parturition without convulsions. Therefore it will not do to conclude that the kidneys are responsible to a degree that will justify us in saying they are the cause. We have convulsions in some cases that seem to be in perfect health; all excretions normal in quantity and quality, not the least departure from a healthy condition, and we have to be contented by charging reflex nervous action. By doing this we concede that there is some abnormal irritation somewhere, possibly *in utero*, and when pressed for the cause of that irritation in a perfectly physiological process, we are stopped, and with our present knowledge have to defer exact explanation and definite statement, saying that reflex action with convulsability is most probably the cause.

In considering the treatment of puerperal convulsions, I shall divide them into two distinct and widely different classes. I do this because I think we need different lines of treatment. While patients are considered eclamptic, we must, I think, divide them into the sthenic and the asthenic; the healthy and the diseased; the robust and the feeble; the well-nourished and emaciated; the plethoric and the poor.

The first class we call sthenic—healthy, robust, presenting every indication of vitality, most likely to be a primipara—has not had an indication of disease since conception, but will say that her health has been unusually good. The first and only symptoms that the experienced accoucher regards with suspicion, will be a flushed face, a morbid activity of the mind, possibly accompanied with slight pain in the head, symptoms which are concomitant with the approach of labor. Suddenly, without further warning, a strong convulsion seizes the patient, that is so potent and terrible in its manifestation as to not only try the strength of her couch but in some instances to produce perceptible vibrations of the house. Here we have convulsability by reflex action, and without any known septic trouble.

Forty years ago the United States imported 72,000 pounds of opium; in 1880, 372,000 ponnds; and in 1893, nearly 1,000,000 pounds. This increase is largely out of proportion to the increase of population and the legitimate demands of medicine. The medical and surgical world were never more united upon any one measure than on the effort to discourage the use of opiates in many diseases where it was formerly thought and taught to be *sine qua non*.

Within the twenty years of my practice, I can see that not more than one-fourth as much morphine is used now as was used when I began work. The teaching of today is, when in doubt as to the propriety of an opiate, do not give it.

The medical profession, then, is not to be censured for the increase in the consumption of morphine. Its use is continually discouraged by all reputable practitioners of medicine.

Of course in the last stages of incurable diseases, such as cancer and such like, a sufferer is excusable if he uses the drug, but not otherwise. The physician is frequently unjustly blamed because Mrs. A., or B., or Mr. C., or D., uses an opiate. In not one case in a thousand of this kind should any blame attach to the physician, because had he or she never taken a dose of an opiate except when it was prescribed by the physician, there would have been no trouble; but once having found relief,

tient, and with her despondent, dreadful forebodings. She tells her attendant that she has not been well during the entire term of gestation, and she tells the truth, for her gradually increased septic condition has made life a burden to her. This class is seldom found among the primiparæ, and instead of mental activity we have dullness and despondency, the heart's action is feeble, with every indication of low vitality.

The treatment for this class must be conservative—no blood letting, no active purgation, but morphia hypodermically, hydrate chloral *per enema* to the extent of controlling the spasms; speedy delivery if possible, and when accomplished nutritious diet and stimulants, because although the spasms may have ceased, the danger is yet very great and the tendency is to die from exhaustion. However careful we may be with treatment this class will furnish a large per cent. of the death-rate attributable to puerperal eclampsia.

THE OPIUM CURSE AND ITS PREVENTION.

T. J. HAPPEL, A.M., M.D., TRENTON, TENN.

In a paper written a few years ago, entitled, "Morphinism in its relation to the Sexual Functions and Appetite; and its Effects on the Offspring of the Users of the Drug," I gave a detailed account of eight families in which the mothers were addicted to the use of morphine. Since that paper was completed and read, I have had occasion to note the effect of the drug in a few other families, and the results have served to confirm the views set forth in that paper, *viz.*: That the children of mothers who are habitual users of the drug, in the majority of cases die within a week of birth, cyanosed from an incomplete development of the heart. Second: That if they survive the first year, they are puny, delicate, nervous children, lacking in everything going to make up a well-equipped boy or girl, mentally and physically. Third: Should any of the offspring of such mothers attain to adult life, they become either morphine habitues, or drunkards. That the effect upon the mother is such as to transmit to her offspring the disease as a heredity, just as tuberculosis—not that the disease itself is transmitted, but that "a condition, a soil, a nidus, or whatever you may please to call it, is handed down to the child, and some fortuitous circumstance develops the disease."

If this be a true picture, and I am constrained to believe that it is, a great responsibility rests upon some one to proclaim the evil everywhere and to enforce every possible means of preventing it. The most important branch of medicine today is that of prophylaxis. Disease is easier to prevent than to cure. To cure this curse, the using of the drug must be prevented. Once in its toils, to abandon the use of it is one of the greatest undertakings. It has been truly and aptly said, that to abandon its use is to suffer the tortures of the damned. Further, without the full and free consent of the patient, and his or her hearty co-operation, to break the morphine habit is well nigh impossible. I would say nothing to discourage any one, but my own observation teaches me that it is far easier to abandon alcohol than opium. The using of opium is increasing daily. Public sentiment cries out more loudly to-day than ever before against the use of alcoholic drinks. Public opinion is against it. The dram-drinker is not countenanced in polite society. All business enterprises and corporations discriminate against those who use alcohol. The great railroad systems put as a first question to an applicant for a position in their employ: "Do you use alcoholic drinks of any kind? If so, how much, and what?" Not content with the answers of the applicant, his character upon that point is closely investigated at home where he is known. Should it appear that he uses intoxicants, he is at once refused a position. Further, an employee is at once dismissed if found at all under the influence of liquor. One drink is recognized as, to that extent, unfitting a man for a

trustworthy position in the employ of the company.

One of the most important questions in all life insurance applications is: "Does the applicant use any stimulant in the form of any alcoholic drink?" Should it be shown that he is a regular drinker, he is at once rejected. The fraternal orders are all blacklisting saloon keepers and bartenders.

These things are cited to show the current of public opinion. The retail sale of liquor is regarded by communities as disreputable, but are we not straining at a gnat and swallowing a camel?"

Forty years ago the United States imported 72,000 pounds of opium; in 1880, 372,000 ponnds; and in 1893, nearly 1,000,000 pounds. This increase is largely out of proportion to the increase of population and the legitimate demands of medicine. The medical and surgical world were never more united upon any one measure than on the effort to discourage the use of opiates in many diseases where it was formerly thought and taught to be *sine qua non.*

Within the twenty years of my practice, I can see that not more than one-fourth as much morphine is used now as was used when I began work. The teaching of today is, when in doubt as to the propriety of an opiate, do not give it.

The medical profession, then, is not to be censured for the increase in the consumption of morphine. Its use is continually discouraged by all reputable practitioners of medicine.

Of course in the last stages of incurable diseases, such as cancer and such like, a sufferer is excusable if he uses the drug, but not otherwise. The physician is frequently unjustly blamed because Mrs. A., or B., or Mr. C., or D., uses an opiate. In not one case in a thousand of this kind should any blame attach to the physician, because had he or she never taken a dose of an opiate except when it was prescribed by the physician there would have been no trouble; but once having found relief, the patient concludes that he can free himself from pain and at the same time save the cost of calling the physician, by bringing out the morphine bottle or the opium pill that had been put by for an emergency. Relief once obtained in this way, invites another trial; soon the habit becomes fixed and the party becomes a morphine habitué, or an opium eater or smoker.

Is the physician to blame in such a case? Nay, verily! He did right. The patient must shoulder the blame. The severity of the pain when the physician was called, demanded relief, and a relaxation of the spasm of the muscles was necessary before the cause of suffering could be removed. For this purpose the opiate was given. The physician had nothing to do with the subsequent doses. Had they not been sold to the patient, he would not have been tempted and would not have fallen. A dose of an opiate, excepting paregoric or laudanum, should never be administered, save as ordered by a physician.

On September 13, 1894, this fact was most forcibly impressed upon my mind. I was called to see a two-year-old child suffering enteritis. The patient has been well treated by the attending physician, but with no improvement. On consulting in regard to the case, a course of treatment was readily agreed upon, and it was remarked by the attending physician that he had not been able to quiet the child with what he considered full doses of an opiate, repeated every two or three hours. The mother, when called and questioned in regard to the dose of paregoric given, stated that she was administering a full half-teaspoonful every two hours, but that it had no effect upon the child. To an inquiry as to whether she had ever given the child any form of an opiate, she answered that she occasionally gave it a small dose of morphine; that she began using it for the relief of crying spells, when younger. Asked to show how much morphine she gave at a dose, she measured out a full third of a grain, for a child about two years old—fully seven times the usual dose. This at once revealed why no effect had been obtained from the medicines already administered. This dose of morphine was measured from a bottle produced from the family medicine shelf. No physician had ever advised morphine for the child.

Too often is it the case, the first investment made in a family when a child is born, is a bottle of "soothing syrup;" "Bateman's Drops;" somebody's "quick cure for colic," or some such-like remedy. All of them are sold warranted to contain no morphine or opium. The various consumption cures and cough remedies,

with high sounding titles—too many, with the certificate of some business man, lawyer or preacher appended, attesting their virtues—put upon the market at the present time and sold over the druggists' counter, are to blame for many a ruined member of society, cursed with the opium habit. This is not overstating the matter—rather understating it. Ninety-nine out of every hundred of these various preparations sold, contain opium in some form although they state upon their faces that they contain no "morphine." They may not contain simply morphine, but the foundation is some preparation of opium, and they sell because they stop the cough and make the "patient feel good." A dose of paregoric, laudanum, opium or morphine would do the same. Once having obtained relief, that patient advises some one else of the wonderful relief and benefit he, or she, obtained and the new victim tries it, and soon another fully-fledged opium habitué results.

Should a dose of such stuff be given to the offspring of a morphine-using mother, the smouldering fire at once begins to burn. The thing necessary to develop the habit has been given—the match has been applied to the rubbish pile, and it at once blazes up and burns with a flame that can not be subdued. Doctor Crothers, of Hartford, Conn., cites many cases in proof of this statement. One will answer my purpose. "To parents, both neurotic and probably opium users, a child was born. They died, leaving the child nervous and irritable. Morphine was accidentally given to quiet it, and from that time forward it became delirious without a daily dose of morphine. At five years of age, it died a confirmed morphine user." The literature of the day abounds in such cases. Was the physician to blame there? Nay, verily!

I have, in my own experience, met with a similar case where two sons, born to an opium-eating, morphine-using father, shortly after budding into a promising young manhood, began the use of whiskey and morphine, and soon became wrecks mentally, morally and physically; one dying not long since; the other being, in every sense of the term, a wreck. Though living, he is worse than dead.

Dr. Jules Rochard, in *Le Union Medicale*, draws a gloomy picture of the increase of the morphine habit in France and elsewhere. The habit, he finds, becomes incurable at the end of six months of indulgence. The fair sex and the doctors are, in his opinion, most deeply addicted to the use of morphine. Women seek less to hide the vice than do men. As a rule, men, and especially medical men, take the greatest pains to hide their vice—hence the number of those who use the drug cannot be correctly estimated.

In many cases parties have used the drug for years, without being suspected of such a habit. The current literature abounds in many such cases. A few years ago I was treating a medical friend in a case of pneumonia. I was much worried by the irregular effect obtained from the medicines administered, and, at the time, suspected that an opiate was being used, but could get no positive proof of the matter. A few days since, I learned beyond question, that my quondam patient was a confirmed morphine user. These are not exceptional instances. Numbers of just such cases, not only among medical men but also among the laity, are cited in Hare's *Practical Therapeutics*. This ability to conceal the habit is one of the distinctive points in the use of alcohol and opium.

A native Chinese preacher, in comparing the two vices, stated that he found this one striking difference between the effects of the opium vice among the countrymen, and those produced by alcoholic intemperance among Americans: "When the Chinese opium-smoker comes homes at night, he does not abuse his children and kick his wife; his wife kicks him."

The use of opium, in some of its forms, is in my opinion, on the increase, and whilst the medical profession cannot be blamed therefore, it should, however, be held to some extent responsible for the state of affairs, because, standing as we do or should, upon the watch-towers, we do not proclaim boldly to the families under our charge, the dangers lurking in the use of all such remedies. We do not make proper inquiries about the progress of our little ones, and keep the parent posted upon the various household remedies administered. Many deaths have been reported of children a few months old, from unknown causes, where a careful inquiry would show beyond cavil that they were cases of opium poisoning.

I need not pursue this branch of my

subject any further. Any one by a little investigation can establish the truth of it. The druggist sells the medicine, which he buys, for the money that is in it. He does not trouble himself about the composition of it. He reads the label, notes what it claims to cure, and when a human being calls for a remedy to meet a certain ailment, he recalls the fact that he has on his shelves a bottle warranted to cure just such a case. He takes it down, assures his victim of the efficacy of the mixture, and sells it to him, pocketing at the same time a handsome profit. The remedy may do more harm than good, yet the druggist is not responsible. He has the stuff for sale, and the man wanted it and got it.

This could be prevented: First, by allowing no patent or proprietary medicine to be sold over the counter, which does not show on its label its true and exact composition. Any falsification in such matter should be punishable by a heavy fine. Second, no one should be allowed to sell drugs who is not a qualified pharmacist. In other words the present pharmacy law should be improved and made to apply to the whole State.

Were these ideas carried out and enforced as laws, all "soothing syrups," "consumption cures," "microbe killers," and such like would show upon their face their exact composition; and the mother would know with what deadly stuff she was drenching her child; would realize how rapidly she was laying the foundation upon which, in time, would develop a fully-fledged opium-eater.

In the next place, the law regulating the sale of poisons should be rigidly enforced. It reads as follows:

Milliken and Vertrees' Code. Art. E., Sec. 5635. "Any person who sells or delivers any poisonous liquid or substance, in addition to having the word poison printed or written on the label as now required by law, shall note in a book kept by such person for that purpose, the name of the person to whom such poison was delivered, the date of delivery and the kind and amount of such poison so delivered, and shall keep such book open for public inspection."

Sec. 5636. "Any person violating the provisions of this article shall on conviction be fined not less than $20, nor more than $100. This article shall not apply to the prescriptions of regular practicing physicians."

Sec. 5637. "Any person, except a practicing physician in prescribing for a patient, who sells and delivers any tartar emetic, laudanum, morphine, or other drugs or medicines, without having the common name thereof written or printed on a label attached to vial, box, or parcel containing the same, shall, on conviction be punished as provided in the preceeding section."

Sec. 5638. "Any person who sells to any child under ten (10) years of age, any poisonous liquid or drug, without an order in writing from the parent, guardian, or other person having the legal care of such child, designating such drug either by its name or effect, shall, on conviction be punished as provided in Section 5636, and may also be imprisoned in the county jail not more than three months."

The provisions of the law are plain. Morphine, opium and laudanum are poisonous, and will kill with as much certainty as will strychnine, arsenic and such like poisons.

Not one druggist in one hundred complies with the law. No register is kept in which to note the sale of poisons. Any thing called for is sold, and no questions are asked, except, "where is the money?" When that is produced, the sale is completed and the drug is delivered. Often and over, a child of less than ten years of age, steps into a drug store with a fifty-cent piece and a small scrap of paper, inscribed with one word "morphine." No name is signed. No questions are asked. The bottle of morphine is wrapped up and passed to the child over the counter. A death may follow on the sale, but the morphine cannot be traced. No register is kept in which the sale is noted, and hence no proof exists that A. or B. sold the poison, and no prosecution follows. Druggists say that the amount of opiates sold is beyond the comprehension of the average doctor, even: that they sell it day by day without knowing or even inquiring for whom it is bought. Such should not be the case, but so long as any irresponsible party, or child of tender years can buy without let or hindrance, the awful traffic will grow.

If the laws were enforced to the letter, and the name of the purchaser of every grain or morphine entered in a public

ledger open to the inspection of friend or foe, where the buyer did not present the prescription of a reputable physician for the drug, a halt would promptly be called. Even a chronic opium-user would draw back and hesitate to allow the public to know the quantity of the drug he or she consumes, for it is an incontrovertible fact, that open and notorious morphine habitues will always minimize the amount of the drug used. Time and again, in answer to the question as to how much the individual used, have I been given a quantity of about one-third, or one-fourth of the amount that I knew was consumed. The opium-eater does not want the public to know how much he consumes. The habit is carried on in secret for years, till it bursts upon the public in some unexpected way.

The user of the drug will sacrifice money, place, position, honor, nay verily, in some cases even virtue itself, to obtain the vile stuff, and until some sacrifice of this kind is made upon the altar of appetite the habit remains concealed. It is a habit more seductive than alcohol, because, so to say, for a long time it can be kept as a private vice, whilst the habit of using alcoholic drinks cannot be kept long concealed. The odor upon the breath, the bloom upon the nose, the flushed face, the protruding abdomen, and many other signs soon proclaim the dram-drinker, whilst opium can long be indulged in without being generally known. The sleepy state as the drug wears off can be accounted for by a rest broken by watching a sick friend, or an undue nervousness from some cause.

The female sex does not often, in the country and small towns, become addicted to the use of alcohol, while opium claims more of them as its devotees than of the male sex. The latter attracts men and women; the former, as a rule, men only.

If the vicious habit, the use of opium in any of its forms, imposed a penalty only upon the person using, then the damage done would not be so great, but the unborn child suffers—the evil is entailed. The sins of the mother are visited upon the children of even the third and fourth generations. The child, through no fault of its own must suffer from the evil habits of one or both of its parents. This state of affairs should not be. The strong arm of the law, which looks closely after the monied interests of the child left an orphan, should be invoked to prevent a far worse condition than that of a moneyless orphanage. The child with no constitution at all, or with one leaning to vice and immorality, is a proper charge upon the State. If the State does not engage in prophylaxis, later on she will find that curative measures are both costly and, in many cases, without favorable results. Let, then, the physician do his part, and the laity do its part. Let both see that the existing laws are carried out to the letter; let them work together to get better laws enacted, and a great step will be taken in the fight against opium. Prevention is better, and more available in this instance than any other course.

As both a preventive and a curative measure, all chronic inebriates and opium-eaters should be committed to the insane asylums for treatment, and kept there until completely cured. No half-way measures should be taken in such cases. Laws should be passed broad enough in their scope to reach all such cases, and so drawn as to meet all objections that could possibly be urged upon the grounds of personal liberty. Opium users should to all intents and purposes, be treated as persons dangerous to the public, and not permitted to be at large.

The insane dodge is set up by them, when they violate the laws of our State, and this method of treatment simply would recognize the possibility of the existence of such a condition.

This paper has been written to air no pet theory of my own, but to invite the attention of the society to a great and growing evil.

1. Make our druggists obey the laws. Protect ourselves against them.

2. Let the patients know that if they will use the drug the unborn generation shall be protected, so far as it can be done, by putting the users where the drug cannot be gotten and the habit is broken.

ANTISEPTICS IN OBSTETRIC PRACTICE.

G. B. GILLESPIE, M.D., COVINGTON, TENN.

One does not hear, now-a-days, of a lying-in hospital being closed on account of an outbreak of puerperal fever; even the old "milk fever" is banished from the lying-in chamber, and the puerperium must be afebrile.

The Preston Retreat in Philadelphia, shows a record of over thirteen hundred deliveries without a death, and ante-partum and post-partum doucheing of patients, with full antisepsis on part of doctor and nurse, is practiced there. Philadelphia has reason to feel proud of this institution's statistics, which leads the world; yet other maternity hospitals can show almost equally good results.

These institutions are built for the sole purpose, and are fitted up with the latest devices in the way of sanitary plumbing, etc., for the guarding from harm of those who are compelled, in time of need, to take refuge within their walls.

If antisepsis is needed in such places, how much more is it needed in the homes of the rich, where it is so usual to find a water-closet immediately adjoining the bed-chamber, or a wash-basin connected with the sewer in the room. The poor, while they may not possess these questionable luxuries of the rich, yet are equally exposed. How often is a bucket filled with filth found standing just outside the door of the room.

Great numbers of cases of puerperal peritonitis are caused by the carelessness of the accoucheur in handling the puerperal woman; and with unclean hands, or with imperfectly cleansed instruments, you will realize how easy it is to carry the disease from one patient to another. Cleanliness is the best disinfectant. Parturition is a physiological process, but in a certain sense, it is likewise a surgical case in which the vagina is full of minute abrasions, if not torn in places, and affords numerous receptacles for the introduction of septic material. The surgeon does not leave unprotected any avenue by which infection may reach his patient. Why should the obstetrician?

On being called to a parturient woman, I first order an enema to clear the bowels of all accumulation of fecal matter within the rectum; then have her washed about the genitals with warm water and soap, and dried with a clean towel. Afterward I use an antiseptic douche. I prefer carbolic acid or creoline. The hands should be thoroughly washed with hot water and soap. I generally use Johnson's Etherial Antiseptic Soap, scrubbing with a nail brush, drying my hands on a clean towel, and dipping them in a 2 per cent. solution of creoline before making a vaginal examination.

I make as few examinations as possible, but enough to render such assistance as might be necessary. I never allow a nurse to examine a patient after I take charge. If I have to use instruments, I take the same precautions in rendering them thoroughly aseptic as in any other surgical case. As soon as the child is delivered I apply an antiseptic pad, made of borated cotton, over the vulva, and as soon as practicable proceed to deliver the placenta—usually in five or ten minutes—exercising special care to remove all the membranes, not by twisting, as some recommend, as it often tears them in two, but by very gentle traction so as not to break them. If the delivery is a natural one, I dispense with the post-partum douche, unless there is special indication for its use. I then have the parts washed with clean warm water, which has been previously boiled, if I can get it; dry with a clean towel or cloth; apply the antiseptic pad; remove the slip-sheet and put a clean one on the bed over the oil-cloth, which should be a new one; and have the patients' clothes changed if soiled at all.

On the first appearance of any offensive discharge, I use an antiseptic douche of two per cent. carbolic solution twice a day. If it is an unusually hard or instrumental delivery, I use on the completion of labor, an intra-uterine douche of sterilized warm water; but if I am not satisfied as to the cleanliness of the water, I use a 1:4000 bichloride solution being particular to have my syringe thoroughly aseptic. If there

is a lacerated perineum, it is duly repaired. If involution does not occur at the proper time, or should there be hemorrhage, I at once curette and pack the uterine cavity with iodoform gauze, removing it the next day and re-packing if necessary; but seldom find it necessary.

When this antiseptic method is strictly carried out, we are never annoyed by seeing our patients suffering with any of the septic fevers of the puerperal state.

"Dirty and careless midwifery is, to-day, a too fruitful source of pelvic disease."

HYGIENE OF CIRCUMCISION.

W. FRANK GLENN, M.D., NASHVILLE, TENN.

When Moses, in great wisdom, was given out laws and rules for the government of the chosen people of God, every edict was considered as applying solely to their future existence. In other words, for the benefit of their souls. Everything seemed to have purely a religious meaning without any reference to their earthly existence whatever.

But if we will read his various addresses to the Israelites, we will find not only laws for the good of the soul in its eternal existence, but a magnificent code to govern intercourse with each other while on this earth; an almost, if not a perfect set of rules to be observed solely for the benefit of their physical organization. Moses, the great and wise law-giver of Israel, therefore divided his laws into three distinct sets: First, those which pertain to the salvation of the soul; second, those which would insure a pleasant and happy relationship with each other; third, realizing that there could be no spiritual comfort nor any happy domestic relations without physical health, he gave them a code of hygiene, the observance of which would preserve their bodies in the highest state of physical perfection.

An example of the first is the following:

"Thou shalt have no other gods before me."

An example of the second is:

"Thou shalt love thy neighbor as thyself."

An example of the third is:

"And on the eighth day the infant shall be circumcised."

When the circumcision of every male child on the eighth day after birth was made a religious duty, it was, in my opinion, void of any real religious meaning, but was executed solely for their benefit as a physical race. Had not the religious penalty been attached its observance, it would not have been so scrupulously carried out. Had Moses simply said that every male child should be circumcised, because it would tend to prevent in future years, certain habits and diseases which would impair the mind and body, render them weaker men and slowly but surely weaken them as a race, little attention would have been paid to it. But when the law came as a command from God to his chosen people, attaching thereto a reward in eternity, it was then, as it is to-day, strictly observed by Jews. Whether as a religious rite it serves, or did serve, any purpose to the future happiness of the soul, it is not my province here to discuss; but that it is one of the grandest hygienic measures suggested to man, I most fully believe.

Now, following the subject directly, we ask: In what way does the simple act of removing the foreskin prevent disease and preserve the health of man?

In answer to this important question, I first make this assertion, which I do not believe can be successfully disputed. There are two things in the world which do more harm to the human race, physically and mentally, than all things else with which we have to contend. These are masturbation and syphilis.

When we stop and consider how many physical disorders, as well as mental derangements, are dependent directly and indirectly upon one or both of these causes; and again, how their influence tends with each succeeding generation, to deteriorate the human family, we are simply appalled. As the blood-vessels permeate and ramify

through every tissue in the body, so the pernicious influence of these disorders pervade, to a greater or less degree, the entire human family. Then, under the idea that prevention is better than cure, anything that would wholly or even partially stop the evil effects of masturbation and largely lessen the spread of syphilis, would be of untold benefit to individuals, as well as a public good to mankind.

Just such a good the simple act of circumcision accomplishes, and I hereby submit what I consider positive proof. About one year since, I had a stereotyped letter forwarded to the leading Genito-Urinary specialists of the United States. The letter read as follows:

"Dear Doctor:

What proportion of Jews to Gentiles have you been called upon to treat for the evil effects of masturbation; also what proportion of Jews to Gentiles have you treated for syphilis?"

This letter was mailed to the following gentlemen: Chas. F. Bovan, Baltimore, Md.; Samuel Alexander, New York City; Hunter McGuire, Richmond, Va.; J. William white, Philadelphia, Pa.; A. T. Cabot, Boston, Mass.; G. C. Greenway, Hot Springs, Ark.; H. H. Mudd, St. Louis, Mo.; Prince A. Morrow, New York City; F. H. Watson, Boston, Mass.; E. C. Burnett, St. Louis, Mo.; J. Nevens Hyde, Chicago, Ill.; N. Senn, Chicago, Ill.; A. S. Garnett, Hot Springs, Ark.; R. W. Taylor, New York City; L. Bolton, Bangs, New York City; W. K. Otis, New York City; C. H. Masten, Mobile, Ala.; J. W. Brinton, Philadelphia, Pa.; Edward H. Martin, Philadelphia, Pa.

Here are some results from the answers:

Syphilis equal in both, 2; no record retained, 8; a marked difference, 9.

Now, as will be seen from the above answers, not a single one has been called upon to treat an Israelite for an extreme evil resulting from masturbation, which proves conclusively that boys circumcised before the age of puberty do not masturbate excessively. The reason for this is plain. When the foreskin is removed, the epithelial layer of the glans penis becomes thickened and dry and is therefore not so sensitive, while with a long prepuce, the glans is kept constantly moist, soft, and, on account of accumulated decomposing secretion under the foreskin, is more or less irritated and congested. This condition of the glans penis at and after the age of puberty, would undoubtedly have a tendency to exaggerate the natural sexual desire and one prone to seek pleasant relief in the most convenient way. Having a long foreskin with which the necessary titillation can easily be made, self-abuse is a very natural consequence. The condition, therefore, of a glans penis in a boy with a foreskin, at and after puberty, is as follows: A thin epithelium, kept constantly moist, covered by thick, flaccid skin. On account of this foreskin having confined underneath it a constantly decomposing secretion, a congested and hyperaesthetic condition exists. This physical condition, coupled with the usual ignorance of boys on the subject of masturbation renders it a very natural temptation.

Now when the prepuce has been absent since infancy, what is the condition? There being no prepuce to lubricate, the secretion ceases; by years of friction with the clothing the epithelium of the glans penis becomes very much thickened. Being, therefore, thick and dry, there is not unnatural sensitiveness. If masturbation is indulged in, there is no foreskin to use and the friction of the naked hand frequently abrades the glans penis and causes soreness and pain. The records show that circumcised boys do not masturbate excessively, while uncircumcised boys often do.

The glans penis of a circumcised person is almost, if not entirely non-absorptive when it is unabraded. But the glans penis of an uncircumcised person is a very good absorptive. When such a person comes in contact with syphilitic poison, it is very apt to be absorbed and innoculate the system, whether there is any abrasion or not. In a glans penis, however, that is dry and has a thick epithelium, with no abrasion, it is almost wholly non-absorptive and there is little if any danger of contracting syphilis, even if contact is made.

Now, as the simple act of circumcision almost wholly prevents the many evil results following excessive masturbation and largely decreases the number of cases of syphilis, it presents itself as a most important hygienic measure. We, as medical men, should urge its performance on every male child very soon after birth.

Irritation, inflammation or contraction of the prepuce in children, frequently causes severe reflex troubles, such as irritation of the bladder neck, extreme irritability, nervousness, convulsions and has been claimed to be a potent cause of hip-joint disease. The many misfortunes that may befall a person with a long and useless foreskin, appeal to us as medical men interested in the preservation of the health of mankind and the prevention of disease, to urge early circumcision in every male child without exception.

If we would improve our race of men both physically and mentally, we should educate the youth of the land thoroughly in sexual hygiene. We should teach the boys that they should not have an emission from any cause before the age of twenty-one, not only from a moral standpoint, but, mainly, for their own health and happiness in future manhood. There is no good sense or reason in granting a male liberty to masturbate, have intercourse *ad libitum*, have gonorrhœa frequently and syphilis, without tarnishing his respectability or his eligibility for marriage, while the young lady he asks to be his partner for life is to be as "chaste as the icicles covered by frosts of purest snow, that hangs Diana's temple."

While such has been, and is still, the custom of society, custom does not make a wrong right, and we, as guardians of the health of the people, should begin the reformation.

We should teach fathers (that they may teach their sons), the dangers of masturbation, of gonorrhœa and of syphilis, and urge them as earnestly to avoid these evils as they are enjoined to shun the gambling hell or the drinking saloon. If every father would have all his boy babies circumcised, then, as they approached the age of puberty, explain fully to each the dangers of masturbation, gonorrhœa and syphilis; educate them to make passion their slave and not be passion's slave, before long we would realize that man is only "a little lower than the angels."

COMMUNICATIONS.

FAT IN PULMONARY CONSUMPTION.

THOMAS J. MAYS, A. M., M. D.,* PHILADELPHIA, PA.

Fat is one of the most important, though one of the most unstable constituents of the human body. It gives weight, rounds off the angular outlines, and protects against cold and injuries. Normally it fluctuates with the cycle of the seasons, diminishes rapidly in disease, and speedily returns during convalescence. Its diminution marks one of the earliest symptoms of pulmonary consumption, hence the index which is afforded by the weighing scale forms an element of precision in the diagnosis and prognosis of this disease.

What is the source of fat in the animal economy? Is it derived from the outside as fat, or is it manufactured by the body from other food? These are questions of great physiological and clinical significance in relation to the disease under consideration. There are two great classes of foods: the proteids, or albuminoids; and the fatty and starchy foods, and there was a time when the animal body was likened to a steam engine, inasmuch as it was believed that the proteids furnished the material for the structure of the machine, while the fats and starches were oxidized and gave the necessary force to keep the machine in motion. According to this view the fat of the body is derived from the fatty and starchy foods, and is used at once, or stored up for future purposes. This view is not strictly true, as will appear further on.

The fat of the body is contained in

*Professor of Diseases of the Chest in the Polyclinic, and Visiting Physician to the Rush Hospital for Consumption in Philadelphia.

cells which are composed of protoplasm and possess nuclei. The cells abound in the interstices of loose, connective tissue, and are found under the skin, especially in the soles of the feet, the palms of the hands, buttocks, female mammary gland, around the synovial capsules of the joints, in the orbits, in the medullary canals of bones, in the surroundings of the kidneys and the omentum, and on the surface of the heart.

When an animal fattens it appears that oil globules are formed within the fat-cells. These globules increase in number while the protoplasm of the cell diminishes. These globules are not deposited in the cells in a mere mechanical manner, but they are formed by the cell itself and at the expense of its own protoplasm, which becomes very much attentuated. It seems, therefore, that the fat of the body is as much a secretion of the fat-cells as pepsin is a secretion of the peptic glands, or as the oily matter of the skin is the secretion of the sebaceous glands, or as the fat of milk is the product of the cells of mammary gland.

From the fact that the protoplasm of the fat-cells undergoes metamorphosis when the oil globules form, it seems quite obvious that other than fatty food is used by the body in the manufacture of fat, and that in all probability proteid or albuminous food is used for this purpose. It was shown by Liebig long ago that fatty, starchy, and saccharine foods do not form the exclusive supply of fat in the body; for the butter in the milk of a cow far exceeds the scanty supply of fat in her food, and the wax which is produced by bees is out of all proportion to the amount of sugar which they consume in their food. The feeding experiments of Lawes and Gilbert also demonstrate "that for every 100 parts of fat in the food of fattened pigs, 472 parts were stored up as fat," showing, therefore, that fatty foods only supply about one-fourth of the fat which is contained in the body.

That proteids form on important source of fat in the body is evidenced by the following facts: Microscopic observation shows that the fat of milk is formed by the epithelial cells of the mammary gland through the probable metabolism of protoplasm. Fat in milk is largely increased by albuminous, and diminished by fatty foods. When cheese "ripens" its proteids are converted into fat. Milk sugar is maintained is abundance in the milk of carnivora even when fed on an exclusive meat diet (Foster). Fatty degeneration, as is often witnessed in the heart and in other important organs, is further evidence that proteid substances are converted into fat.

By this I do not wish to convey the idea that albuminous foods supply the greatest part of the fat to the body; nay, we know that this is done by the carbohydrates; but I desire to lay special emphasis on the fact that fats and oils do not play the important part which they are popularly supposed to do in the nutrition of the animal body, and on the further fact that proteids are of greater value as fat producers in pulmonary consumption than they are generally believed to be. In fact, evidence is not wanting to show, as has already been hinted at, that both fats and carbo-hydrates diminish the metabolism of the body, while a meat diet enhances the same, increases the oxidizing activity of the body, multiplies the number of red blood-corpuscles, and leads to a rapid consumption of fatty and carbo-hydrate food. A great deal of harm has followed the doctrine that the fat of the body only comes from the fat of the food, and that therefore the only way to fatten a consumptive is to ply him with fats and oils of various description. Every experienced physician knows that oil and fats produce dyspepsia in many such patients, and do no good in some with whose digestion they seem to agree, while there are a few who thrive under their use, but whose fat does not seem to have any staying qualities. It seems to me that oily and fatty foods only confer a real benefit on a minority of consumptive sufferers, and that much greater service is rendered to the nutrition of such patients by the administration of albuminous foods, the important ones among which are freshly expressed beef juice, beef, mutton, lamb, milk, eggs, oysters, clams, liquid peptonoids, beef powder, meat juice, beef peptones, etc.

An important question comes up here in regard to the influence which rest and exercise have on the fattening process of the human body. Is physical activity more conducive to fat-building than rest, or is it not? This may be said to depend altogether on circumstances. There is no

doubt that in health exercise gives both fat and strength, but it is quite different with the invalid. The fat which is stored up in health represents so much surplus capital which is laid up for a rainy day; but the consumptive has no surplus and lives, as it were, from hand to mouth. All his energies are devoted to the maintenance of those bodily functions which are immediately necessary to life, such as circulation, respiration, digestion, innervation, etc., and very frequently these are carried on imperfectly. To him, therefore, exercise is meaningless, for he has no capital to exercise until he gets stronger and lays up some. Hence he must practice economy. He must restrict his outgo and increase his income. This he can only do by resting.

That rest promotes the collection of fat is shown in the fattening of animals. Swine and cattle, which are prepared for the butcher's knife, are not allowed to run loose, but are closely confined; and the geese of Strassburg, which fatten to enormous proportions in a few weeks, are shut up in tight boxes with just sufficient room to project their necks. I have, again and again, observed that with no other change in the treatment except the substitution of rest for exercise, consumptives show a marked and distinctive improvement and gain in flesh.

It is also of great interest in this connection to consider the influence of the nervous system on nutrition; although, owing to the limited time at my disposal, I can only briefly refer to this subject. Whether there are special trophic nerve fibres or not, it is quite clear from the large number of experiments which have been performed, that the nutrition of that part of the body suffers whose supplying nerve is divided or injured. Clinical evidence points out the same. It is well-known that in neuralgia, the limb, or area of tissue to which the affected nerve is distributed, emaciates and loses its fat. Clouston states (*Mental Diseases*, p. 469) that thinness is the almost constant accompaniment of melancholia, and that fattening of the patient is its natural cure; and he furthermore says, that this depraved or weakened trophic energy speedily tends to end in phthisis pulmonalis. In fact, he believes that melancholia has a special proneness to terminate in pulmonary consumption. Phthisis and melancholia run a parallel course in this respect. Emaciation is their common enemy, while fat redeems both, and, according to Clouston, the latter is convertible into the former disease. Are we not able to discern in this a confirmation of the view that a causative relation exists between disease of the nervous system and disorder of nutrition? Is it not probable from this that the building of fat is intimately dependent on the integrity of the nervous system? This probability is strongly confirmed by the therapeutic action of strychnine. It is well known that this agent has no other influence except that which it exerts on the nervous system, and yet I know of no other single drug under the administration of which consumptives fatten more promptly than under strychnine when it is given in gradually increased doses, and combined with suitable rest and nutritious food, as is attested by the following list of cases abstracted from my note-books, which includes those adult patients who have shown the greatest disposition to gain in flesh during the last three years.

(1) N. Second stage; gained ten pounds. Still under treatment.

(2) P. First stage; gained fifteen pounds. Recovered.

(3) W. Third stage; gained twelve pounds. Disease arrested. Is at work.

(4) R. First stage; gained ten pounds. Disease arrested.

(5) O. Second stage; gained sixteen pounds. Disease arrested.

(6) K. First stage; gained twenty-two pounds. Recovered.

(7) S. Second stage; gained twenty-eight pounds. Disease arrested. Is at work.

(8) S. First stage; gained eighteen pounds. Recovered.

(9) E. Female. Third stage; gained twenty-seven pounds. Recovered. Gave birth to a baby a year ago. Remains well.

(10) N. Female. Third stage; gained thirteen pounds. Recovered. Gave birth to a baby a year ago, and expects another in four months. Is doing very well.

(11) J. Disease complicated with empyema. Drainage. Recovered. Gained seventy-three pounds. Is at work.

(12) S. First stage; gained sixteen pounds, Recovered. Is at work.
(13) T. First stage; gained forty-four pounds. Recovered. Is at work.
(14) B. Third stage; gained forty-six pounds. Recovered. Is at work.

While it is true that increase of flesh is always desirable in the treatment of pulmonary consumption, it is a mistake to hold that every patient of this kind must make prodigious gain before recovery can set in.

On the whole I believe that women are less inclined to gain than men, and I have known members of the former sex make an uninterrupted recovery without increasing in weight.

In summing up the principal points in this paper it appears that the fat of the body is manufactured out of carbo-hydrates, proteids, and fats; that for fattening purposes, proteids and carbo-hydrates are superior to fats and oils; that the latter are overrated in the treatment of pulmonary consumption; that carbo-hydrates and fats hinder and proteid foods accelerate metabolism; that rest of the invalid promotes the formation of fat, and that exercise retards it; that in all probability the production of fat in the body is largely under the control of the nervous system; and that strychnine through its stimulant action on the nervous system fattens the consumptive, and increases the number of his blood-corpuscles.

CORRESPONDENCE.

THE SKUNK AS A SOURCE OF RABIES.

EDITOR MEDICAL AND SURGICAL REPORTER:

In the abstract printed in THE REPORTER for April 13, under the above title, the writer says: "And as a final wind up, what is all this pother about? There is not a particle of evidence that the skunk's bite is particularly dangerous."

Is it not possible that the writer may be mistaken? He does not claim that he has ever seen a dog or anything else bitten by a skunk. Nor have I ever seen a dog die from skunk-bite. His evidence, like mine, is all hearsay. He says the belief extends from Texas to Kansas. It also extends through the border States of the United States and Mexico to the Pacific ocean. Every widely extended belief or superstition, is now, or has been in the past, founded on a more or less extensive basis of facts. As the belief travels in time and space, it often gets so loaded with accretions and additions that it is not possible to learn the facts on which it is founded unless it can be traced to its place of origin.

One day a favorite dog of Rancher F—— came up from an encounter with a skunk, with a small scratch on the lip, just sufficient to draw a few drops of blood. An old beekeeper, Mr. O.——, advised that the dog be killed and thus saved suffering, as it was sure to die in a few days. Rancher F—— ridiculed the idea of danger, and declared that in Nova Scotia he had seen more than a dozen dogs bitten by skunks, and their bite was no more dangerous than that of any other animal. The old beekeeper replied that Nova Scotia was a long way off and it might be so there, but he knew that in California the bitten dog always died. I did not stay on the ranch to watch the dog, but when Mr. F—— next came to town, he told me that the dog drank water eagerly but refused food, and died in a few days.

Inquiry among the native Spanish Californians disclosed the fact that the belief in its fatality was quite general. Extending the inquiry among Americans, long resident here, I found some believed it just as fatal as the bite of a rabid dog; others acknowledged it to be dangerous, but thought recovery the rule. To the question why the skunk's bite was fatal to the dog in California and harmless in other places, I got no more satisfactory answer than that given by the old beekeeper, "It was so, because he knew it was so." I began to despair of getting a better solution of the problem, and shelved it for some years.

I had never heard of the belief until I

came to Southern California, and at the outset dismissed the idea of rabies, for only two California dogs were ever attacked by rabies; one in a story printed in Boston, and the other in a tale printed in New York.

One day when putting up some dog medicine for an old stock raiser, who kept a dozen or more dogs, I asked if he ever had lost dogs from skunk bite? "Yes!" "Have any survived a decided bite?" "Yes, one!"

He said that starting one morning to hunt down a California lion that had killed a colt the night before, a two-year-old dog got away from the pack and was bitten by a skunk. He immediately started at full speed for the branch, one-quarter of a mile away, but was overcome by nausea; stopped to vomit; turned round two or three times to get his bearings; was again compelled to stop and vomit; turned round as before, and made another dash, and this was repeated three or four times until, finally, reaching the water he plunged in, leaving only his head uncovered. As the rest of the pack was not contaminated, he concluded to go after his lion, and when he came home shoot the dog to prevent his further suffering. But the lion led him a long chase and it was late in the night when he got back. Next morning the dog was not to be found. A day or two afterward he sneaked up to the feeding ground, but ate nothing; whether from nausea or because he was ashamed of his vile odor, Mr. S—— could not tell. He soon went back to the water and Mr. S—— carried him some food, but could not induce him to leave the water. He left the food for him on the bank for several days, and when Major considered himself sufficiently purified, he came up with the pack as usual. He lived to a good old age, but could never again be induced to approach a skunk, nor long remain where their odor was at all pronounced.

In answer to inquiries, Mr. S—— said, the dog that survived was bitten in the rainy season, while the dogs that died were bitten in the dry season. Have we not here a clue to the solution of the problem. In those places where the bite is harmless, clear, cool, running water is never far to seek; while in that belt where it is believed to be dangerous, water is comparatively scarce. For nine months of the year, streams of running water are small, few and far apart. This is the only solution of the problem I have, and when any one offers a better, I shall be ready to trade or give mine away.

Very truly,
F. R. MILLARD, M.D.,
San Diego, Cal.

NAPOLEON'S FAVORITE PRESCRIPTIONS.

EDITOR MEDICAL AND SURGICAL REPORTER.

Before the present era of Napoleona dies out the two following favorite prescriptfons of Napoleon I. may be of interest to some of the readers of THE REPORTER;

Napoleon's pectoral pill.

Pulv. ipecac..... gr. xxx.
Pulv. scillæ..... } ää gr. xl.
Pulv. ammoniæ..... }

M. ft. et. div. in pil. No. xxxiv.

Sig. Dose, 2 pills night and morning.

The above formula was a favorite remedy with Napoleon for difficulty of breathing, bronchitis, and various affections of the organs of respiration.

Napoleon's remedy for the immediate relief of hoarseness:

Liquor. ammoniæ fortioris ..... m x.
Syrupi erysemi..... ʒ iss.
Infusionis tiliæ florum..... ʒ iiss.

M. Sig. To be taken at one dose.

This formula was, doubtless, an excellent remedy for hoarseness, and could be used even now with some advantage. But as the syrup. Erysemi and the infusion of linden flowers would be rather difficult to procure at the present day, the following formula may answer as a good substitute:

Liquor ammoniæ fortioris..... m x.
Syrup acaciæ ..... ʒ iss.
Aquæ aurantii flor..... ʒ iiss.

M. Sig. To be taken at one dose.

Yours very truly,
CHAS. B. WILLIAMS.
1226 Spruce St., Phil.

DIPHTHERIA.

EDITOR MEDICAL AND SURGICAL REPORTER:

I am sick and tired of hearing such unfavorable reports on the treatment of diphtheria. I do not claim to have had many hundreds or thousands of cases of diptheria within a limited period, but I do deprecate the rigid formality of treatment that is adopted by eminent men in the profession.

My attention has been called to this subject by the lugubrious introduction of Dr. Hiram Corson's article in the last number of MEDICAL AND SURGICAL REPORTER. Dr. Corson is a man of superior intellect and of long experience in the profession, and although I have no pretentions to an extensive clientele or experience, I, like every one else, have my own individual opinions.

Physicians in our day are much too apt to treat their patients by a routine course, regardless of individual symptoms. I wish to state here that I do not have that confidence in the coal-tar products as antiseptic remedies that many of my confreres have.

When we come to discuss the physiological differentia of the individual cases, then of course the treatment must necessarily be modified. Diphtheria is a highly contagious, infectious disease, characterized by a great tendency to malignancy and extension if proper antiseptic measures are not adopted *imprimis*. The period of incubation is surprisingly short, and varies between a few hours and seven or eight days, according to the physiological condition of the subject.

Another point to be taken into consideration is that the violence of *pro tempore* symptoms does not always accord with the severity of the case.

My views on this subject, offered in all humility, are that the initial treatment is always carried out too much on the expectant plan—waiting for more serious symptoms to develop themselves. The main object in the treatment of this disease is to destroy the pyogenic matrix and thereby avoid its extension. My plan is to use nitrate of silver in solution with an atomizer three, four or five times a day, to this effect, and afterward moderately strong gargles of carbolic acid and water. The strength of the nitrate of silver solution to be used with the atomizer is twenty grains to the ounce. As supportive treatment iron tonics, strong beef essences and anodynes *pro re nata*. The systemic treatment, of course, must be varied according to the constitution, hereditary predisposition, etc., of each individual patient.

I respectfully invite a further discussion of this subject. Let us see if we cannot strip this one disease of some of its post-mortem terrors.

Respectfully yours,
Thompson, Pa. A. W. STIMPSON, M.D.

AN OPEN QUESTION.

EDITOR MEDICAL AND SURGICAL REPORTER:

On Sunday evening March 24, at 7 o'clock, the bartender at Burns' saloon shot Thomas Doran in the left thigh. The ball cut the external saphenous vein clear apart, passed through the ramus of the pelvic bone, toward the outside; curved round the hip-joint without injuring it, and lodged in the tissues at the posterior portion of neck of femur.

Two surgeons of this city were summoned at once. Hemorrhage had been copious, but when they arrived it had ceased.

No blood vessels were tied. The man rallied from the shock and gained strength. Friday, March 29, the surgeons were examining the wound, when recurrent hemorrhage came on. The wound was enlarged and the lower end of the cut vein was ligated. *The femoral artery was also ligated.* Patient died two hours later.

I was present at the autopsy; Dr. E. P. Townsend handled the knife. He extended the incision in the thigh one inch upward, through Poupart's ligament, and without opening the abdomen came across the open mouth (upper end) of the cut vein. It was large enough to admit the end of the little finger.

At the coroner's inquest I testified that the upper end of vein should have been ligated at all hazards. Further, that to have ligated it, under the circumstances, would not have increased the shock; that the tying of the uninjured femoral artery was mighty poor surgery; would cause the death of the leg, and, of course, death of the patient.

Would it be right to hang the bartender in the case? JAMES E. FREE, M.D.

Billings, Mont.

TERMS:—Three Dollars a year in advance. Sent four months on trial for $1.00.

REMITTANCES should be made payable to the Publisher only, and should be made by Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We invite contributions of value to the profession, and if published originally in THE REPORTER such will be paid for at liberal rates, or a limited number of copies of THE REPORTER will be supplied, as the author may elect. Hereafter where reprints are desired writers are requested to make a note of that fact on the first page of the MS., but must order reprints directly from the publisher, who will supply the same at cost rates. Contributors should inclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, MAY 25, 1895.

EDITORIAL.

THE SLAUGHTER OF THE INNOCENTS.

Utterly unpremeditated but fully anticipated and awaited with dread, is the appalling sacrifice of infant life which annually, during the hot season, occurs from causes which ought to be and are preventable.

Man is prone to boast that through the development of his own powers he has risen superior to those governing factors which, under natural conditions, inexorably control existence in all forms of life. To some extent this may be true, but Nature has a way of maintaining her laws whether by the use of conditions of her own establishment or by taking advantage of the artificial conditions introduced by man. If in the process of his higher development, man has succeeded in modifying the influence of environment, in making of none effect the principle of natural selection, or in entirely abrogating the law of survival of the fittest, as these obtain under Nature, his successes have been more apparent than real, for he has merely substituted for the natural, artificial conditions which are equally effective for the operation of Nature.

There is a well recognized causal relation between hot weather and infant mortality. In the temperate zones this is so well understood that it has passed into a proverb, and the supposititious danger of the "second summer" is dreaded alike by the intelligent and the ignorant.

Aside from the ills which infant flesh is naturally heir to, much of the awful mortality is due to artificial conditions which could be eliminated simply by the exercise of common sense. These conditions must be regarded as predisposing causes, and the most common as well as the potent are *irrational care, improper feeding* and that irrepressible pestilence that stalketh at all hours—the purveyor of free medical advice. Volumes might be written concerning these advance agents of Death, but attention is now directed to a few only of their many manifestations. So trivial do some of these

matters appear at first, and indeed not within the province of medical practice, that it would seem a work of supererogation to call attention to them were it not that the most casual observer must be impressed with the constant and universal prevalence of these little things which together become so massive. If by exercising its influence, the medical profession can, for prophylactic use, develop among the caretakers of childhood a little common sense, less cerebral energy need be expended devising futile novelties for remedial application.

It is affirmed that of all living animals the infant man is the most helpless and dependent. This is true, but the mere fact that the human infant can survive so much of the carefulness inflicted upon him in his helplessness, shows him possessed of considerable tenacity of life.

The average caretaker of infancy seems to be governed by three ideas which are as unalterable as were the laws of the Medes and Persians. Baby must never be cold; never be hungry; never cry; anything to prevent that.

As an instance of irrational care, notice the clothing of the average infant during hot weather. With the thermometer ranging in the nineties, and the humidity registering near saturation, while adult humanity swelters in seersucker and gauze, drinks freely of iced-water and seeks comfort in a cooling breeze, observe the unhappy condition of the baby whose natural dependence subjects him to artificial caretaking.

Despite every precaution the infant is showing signs of failing health; is very wakeful and restless; will take little or no food, although offered it every time it cries; is fretful and cries constantly; wants to be taken up, and while held will be quiet and go to sleep, but if laid down will speedily wake and cry; seems flushed and feverish; there is an eruption apparent, etc., etc. The caretakers are at their wits' end. They have tried every means known to their ancestors, their friends who dispense free advice, or to themselves, and in despair they send for the physician.

Now if the medical man has the courage, he may give the caretaker a realizing sense of the baby's trouble and at the same time enlighten the understanding as to the simplicity of the remedy—and all without giving a drug to the care-worn infant. The caretaker, clad in the original mode of Eden, must be garmented as follows: A bed-quilt folded, in a similar shape and used for a similar purpose, must be applied in a manner similar to the infant's diaper, the safety-pin need not be securely locked. A strip of flannel, eighteen inches wide and thirty-six inches long, is applied about the abdomen and fastened as is the infant's binder. A long-sleeved woolen undershirt is necessary to protect the upper part of the body. In lieu of fancy socks, old-fashioned knitted woolen stockings may be worn. The next stratum consists of a flannel underskirt of such length that it may be folded back over the feet so far as the hips. If the caretaker has never neglected duty, a thin layer of muslin underskirt, a foot or two longer than the flannel, may be added. Over all, a daintily embroidered slip, in length just twice the height of the wearer. All garments must be fastened with safety-pins, so bent as to easily unlock and permit of excursions of the points.

The caretaker must now be placed, on the back, in the middle of a feather-bed, covered with a blanket and every current of air shut off lest cold be taken. All signs of distress must be relieved by administering lukewarm soup.

The caretaker thus relatively put in the place of the care-sufferer, marvelously speedy would be the solution of the problem of the baby's illness, and the proper mode

of treatment would be a revelation inspired of common sense.

By a single experience of this kind the caretaker would discover: That an infant learns to feel long before it acquires fluency in expressing its opinions. That an infant's physical well-being is not conserved by maceration in its own juices. That thirst is not relieved by the administration of solid foods. That the free exercise of the muscles necessary for the development, and unimpeded circulation, respiration, etc., are not best obtained by swathing the body in tight, hot garments. And that relief for the infants, as for the adult, can best be obtained by exercising the same common-sense in both cases.

Numerous other instances of irrational caretaking will occur to the mind without further mention.

Improper feeding, perhaps more than any other ordinary cause, is responsible for infant mortality. This matter is so generally discussed that it is merely mentioned here.

As for the vendor of medical opinions and cures for all ailments, it is rather difficult to draw the line of exclusion distinctly, for this pestilential affliction assumes all forms, from the impertinent neighbor who boasts as a certificate of proficiency the fact that, "she has had eight children of her own and buried them all without calling in a doctor once," to the importunate relative who would cheerfully sacrifice herself if it would benefit the baby.

One physician obtained some success in forestalling this agency of death and disaster by instructing each prospective mother under his personal care, to procure some practical guide book in the care of children—such as Dr. Starr's Hygiene of the Nursery; to refer all questions of doubt to the decision of such guide; where unanswered, or where the answer was not fully understood, to refer the question to the physician; but under any and all circumstances to absolutely interdict any interferance from other sources, especially rejecting voluntary advice.

He found that this course, while it did not always win him golden opinions from the advisers thus interdicted, invariably proved of benefit to both mother and child, and he has had every reason to felicitate himself upon the advantages gained, and to rejoice in the cordial thanks of his grateful patients.

The plan is worth trying.

ABSTRACTS.

CONCLUSIONS CONCERNING THE KEELEY METHOD WITH DRUNKARDS.

The *Christian Advocate*, May 9, 1895, contains the following editorial:

This article consists of various facts, opinions, and reasonings, in part the result of previous investigations, but chiefly accumulated from correspondence, reading and conversations during the last two years, since our attention was specifically directed to this subject. To save space, promote clearness, and prevent misunderstanding each section will be complete in itself.

In the Appendix last week, to gratify the reasonable curiosity of the reader, we published statistics sent us by non-subscribers on printed postal cards, which were excluded from the table because contrary to the conditions deemed necessary to secure reliable information.

We had received statistics from eminent physicians, allopathic and homeopathic, with a national reputation either as superintendents of hospitals for the insane or as specialists in nervous diseases—none of

them in charge of institutions devoted to inebriety or in any way connected with them; but as none of the writers were subscribers to *The Christian Advocate* they did not come within the proposition. Their letters are important, and for this reason are herewith printed.

The first is from the superintendent of a large State Hospital for the insane:

"We have had five cases admitted to our care that had been treated at the Keeley Institutes. All of these were predisposed to insanity, had been in other institutions, had pursued various courses of treatment for this habit, and were demented by prolonged use of alcoholic liquors to such an extent that their judgment and will power were permanently enfeebled. None have been admitted in which the Keeley treatment was the exciting cause of insanity. After an observation extending over a period of eighteen years, we have come to believe that no treatment for drunkenness is of much value, or any value, where the patient's mind has become demented to the extent that judgment, will power, and self-respect have been lost. Unless the patient is anxious and willing to help himself by avoiding associations in which it is next to impossible to resist drinking, and has will power enough to carry out this line of conduct, he will be subject to frequent relapses."

The second letter is from the superintendent of one of the largest and finest private asylums on this continent, who had an extended general practice in one of the chief cities in the country before becoming connected with the institution:

"Before taking charge of this institution I knew of thirteen persons who had been at one time or another under my care, cases of the excessive use of intoxicating liquors, who went to one of the numerous Keeley Institutes; all, with one exception, of these cases went back to the old habits of inebriety. The exceptional case does not attribute his present freedom from his old habit to the Keeley Cure, but is positively of the opinon that he was harmed, temporarily, at least, both mentally and physically, by the drugs that were used. During the last three years we have admitted thirty-one cases of alcoholic and opium inebriety. Of these, twenty-two, and all of them, with one or two exceptions, of alcoholic inebriety, had been from one to three times discharged as "cured" from various Keeley Institutes. One or two of them had been at Dwight under the personal care of Dr. Keeley, and one of them was at one time one of the strongest advocates of the Keeley Cure in the newspapers. I think it is not at all fair to suppose that my experience, especially as regards the thirteen cases first mentioned, was in any sense unique.

The cases we admitted because of inebriety were accepted by the physicians of the Keeley Institute as curable cases, and were discharged by them as cured. They are not a selected series of twelve failures in thirteen patients, but were the only cases of which I had had, previous to my connection with this institution, any personal knowledge as regards the Keeley treatment.

Of the twenty-two cases which have come under my observation here, none are included in the thirteen previously referred to."

The following is from the superintendent of another State asylum for the insane:

"Five cases suffering from insanity, who had been treated at a Keeley Institute, have been admitted to this hospital within the past two years. All of these patients returned to the use of alcohol or other narcotics, usually to both, within seven months of leaving the institute. Two of the patients while under the Keeley treatment added the habitual use of cocaine hydrochlorate to their other narcotics. Two of the cases were probably insane *prior* to taking the Keeley treatment. One became suddenly insane while undergoing treatment. The other two developed insane symptoms a few weeks subsequent to the treatment. One case acquired a subacute peripheral neuritis, affecting both lower extremities, within a few days after leaving the institute."

The superintendent of a private asylum writes:

"My observation covers forty-seven cases of persons who have come under my care after having taken the Keeley treatment. Of this number thirty-two have been alcoholics and fifteen drug *habitués*. Of my own personal knowledge I know only two persons who have taken the Keeley treatment and who have remained cured until the present time.

It is, however, only just to the Keeley system to say that my position is such that

I know more of the unfavorable results of the treatment than I do of the good."

The following letter is from a clergyman of wide experience and great interest in these matters:

1. Very many of the so-called Keeley graduates are really graduates of other "schools." A number of lapsed persons who told me they had been "through" the Keeley treatment I find upon examination to be the representative products of either the "narcotic cure" or the "gold cure" as applied by other than the Keeley institutes. [It was on this account, among others, that we restricted the testimony to ministers and physicians, who should attest that they personally knew the Keeley Institute to be the one from which the persons included in their statistics were graduates.—Editor *Christian Advocate.*]

2. I find the number of men who have tried some remedy far in excess of my largest surmise.

3. The number of "absolutely cured" drunkards of whom I hear, either from former places of residence or in conversation on railway trains, etc., far out-number those I find myself able to discover upon investigation. Careful investigation always lessens the number of professedly cured.

The keeping of this remedy secret is open to serious objections:

1. It prevents the settlement of the question whether the remedies produce the effect attributed to them.

2. It greatly increases the cost, making it impossible for a large number of victims of inebriety to secure the alleged benefits.

3. So terrible are the consequences of inebriety that common philanthropy would lead to the widest publication of the discovery.

4. The reasons given for keeping it a secret are such as cannot commend themselves to sound judgment and philanthropic motives. For be it understood that this does not profess to be a special remedy for a disease that the medical profession generally knows how to treat; but claims to be the sole remedy for a dreadful malady which defies all other methods.

If Dr. Keeley in keeping this remedy is a true philanthropist, then Jenner, Pasteur, and others were men of poor judgment. To meet this Dr. Keeley could write this sentence:

"As well might the railroad martinet have refused to cross the continent in a palace car, because the process of manufacturing steel rails was for many years a secret, as can physicians eschew the wisdom of sages unless it approaches through the devious ways of a code."

He intimates that a great disaster would result through the immediate possession of his formula by the public, in that all sorts of fake institutes would be established and adulterations of the remedies would take place, which would deceive multitudes, who would lose confidence in the true boon to humanity and be lost. The notion that Dr. Keeley has something that the medical profession of the world, which has made such strides within the last forty years, cannot be trusted with is the greatest tax that was ever attempted to be imposed upon the credulity of the public.

There cannot be much more danger of this than in vaccination, by which process, if improper matter be inserted, the ruin of constitutions, and even death, might result. If Dr. Keeley's attitude be correct, there is no physician who has discovered a prescription for the cure or extraordinary relief of any human malady who would not be justified in keeping it secret.

It is especially absurd in this case because, if made known, unquestionably the reputation of the inventor would have drawn to him more practice than he could utilize without extensive organization and much assistance, and would have caused to roll in upon him continual revenues, so that he would in a short time have accumulated a fortune; while all through the land, in every community, reliable physicians of all schools would be treating diseased drunkards and curing them.

That Dr. Keeley has a legal right to patent and keep his remedies a secret is not to be disputed, but to speak of him as a philanthropist in so doing, or allow him any claim to that high eulogium, is a misuse of language. We fear that "the angel wings of philanthropy are not long enough to cover the cloven foot of self-interest."

His claim that he is the sole discoverer that drunkenness is a disease, caused, and caused only, by alcohol, is an assertion

often repeated, but difficult to sustain. Similar claims were put forth in England as long ago as 1838. The American Association for the Cure of Inebriates, established a quarter of a century or more, laid down this very proposition at the beginning, and refused to receive an establishment that would not treat inebriety as a disease. At the first meeting of the association the dogma was solemnly propounded that inebriety is a disease, and various papers were read by Dr. Parrish, the president, to maintain this fundamental article of faith. Five years later the report of Dr. R. P. Harris, physician to the Franklin Reformatory for Inebriates in Philadelphia, who spoke of drunkenness as a habit, sin, or crime, and did not speak of drunkards being *cured* as in the hospital, but as *reformed*, was rejected in order that he might modify it so as to conform with the society's original declaration.

Dr. Boddington, in England, thirty years ago announced his belief that "all habitual drunkenness is a disease."

Neither is it a fact that Dr. Keeley was the first man who ever said or thought or dreamed that any remedy could take away the necessity which exists in alcohol poisoning for the periodical presence of alcohol. It would be easy to print a long list of alleged specifics which have been as positively recommended, have appeared, and disappeared.

The chief objection to Keeleyism is its theory that all habitual drunkenness is a disease, and the general representation it makes that pledge-signing, moral reformation, religion, and other moral considerations, without physical treatment, cannot deliver men from its thraldom. This and the fallacious statement that 95 per cent. are cured by the Keeley remedies produce the following among other effects:

It leads the drunkard who might reform and ought to reform to consider himself a poor, unfortunate person who cannot reform, and who, if he cannot get the Keeley remedies, is helpless, and therefore may as well be reckless.

It leads many to think that they can reform at any time by retreating to a Keeley Cure.

Drunkenness in the beginning is a vice, one of the consequences of which may be disease. Long ago the terms *oinomania* and *dipsomania* were invented to describe cases where the use of alcohol has caused diseases of the nervous system, with also such disturbances of the mind as to produce a passion to drink which is absolutely uncontrollable; and these cases for a hundred years have been treated in asylums for the insane.

But the condition of an ordinary drunkard is very different. The ordinary drunkard—unless he has come under the idea that drunkenness is a disease, and that he cannot help himself—regards himself, unless utterly brutalized, with shame and remorse. He drank because he liked the taste of it, he liked to be exhilarated by it, he liked the high times he had with his boon companions; but he condemns himself and makes up his mind to reform, until he finds somebody who teaches him that it is a disease. He then concludes that "the desire is uncontrollable, and therefore the indulgence is innocent."

As soon as this theory that habitual drunkenness, or drunkenness generally—apart from plainly insane conditions—is a disease became common, followers of Dr. Keeley, many of them with considerable indirect justification from his sayings, began to disparage pledge-signing, moral influence, and even religion generally. We have letters from Keeley graduates who say that whenever you wish to reform a drunkard, the first thing you must do is to take him to a Keeley Cure, and then bring in the moral teacher and the minister; and some say that it is absolute folly to make any moral appeal to them whatever.

Now, in point of fact, we know that the preaching of Father Mathew reformed hundreds of thousands, and they were associated together in temperance societies, and with the church of which he was the priest, the great majority of them remained reformed.

Also, the Washingtonian movement in this country, with many backslidings, reformed an uncounted multitude who lived perfectly sober to old age, many of them prominent citizens. Great numbers are being steadily reformed by ordinary moral and church influences. Of these we have had the personal acquaintance of hundreds.

There are living, to our knowledge, in this country thirty-five ministers of the Gospel in different denominations, some occupying high rank in this city, who were drunkards, some of them of a very low type. One man, a neighbor of ours,

long a hopeless drunkard, reformed, attained a large practice as a lawyer, had an honored career in the Senate of the United States, and died a sober man. Another became governor of one of the New England States, and the most accomplished man in its entire bounds. We have known men to become insane through drunkenness, be incarcerated in asylums, and there form the resolution to go forth and fight their appetites; and they have won the victory without the help of any drug, hypodermic injection, or magic of any sort.

A large proportion of the converts made by Mr. Wesley and his immediate followers were drunkards, and of these an unusually large number became ministers.

The early revivals in New England, promoted by Edwards, Nettleton, and later by Charles G. Finney, were the means of the conversion of many physicians, lawyers, merchants, and farmers who had been drunkards, and who were brought into active connection with the Church, and there found a field for such energy as they possessed which was not exhausted in their ordinary business pursuits.

Thousands, too, have reformed, and are still reforming, without any help from religion, under the influence of moral, pecuniary, or social considerations. It is in general an error to affirm that every person who drinks is sure to die a drunkard. One of our correspondents says: "I know in this town five men who were years ago confirmed drunkards—two lawyers, two merchants, and one mechanic. They stopped drinking of their own accord, and are now, and have been for seven years, sober men."

In that mysterious circular which Dr. Keeley sent us in the days when he was infallibly curing drunkards with two bottles at nine dollars a pair, he published some observations on drunkenness that are very peculiar; but he must think highly of them, as he repeated them in a circular issued in 1892. He has, in the later edition, made a slight change, which is also worthy of attention. This is as he published it in 1880:

"Christendom has been drinking alcohol for nearly nineteen centuries. Alcoholism is a disease of Christendom. These laws, proven by observation of individuals, are verified by the observation of the people of Christendom at large. The greater number of these people who drink at all begin to drink at the age of eighteen years; the greater number cease at the age of thirty-five years. The greater number of those who cease to drink after the age of thirty-five years never recover from the disease, or, as is generally said, they never reform, and are beyond the reach of Christian and other influences.

"It may correctly be inferred from this verification of statistics that drunkenness or alcoholism, like many other diseases, is self-limited. The average duration of the disease—this heirloom of Noah—is about seventeen years. That there is every possible variation from these averages, intensity of the disease, age, and other points in individuals, is apparent to any observer."

In 1892 he substitutes for the foregoing paragraph this:

"Until now, for the first time in the history of the world, this heirloom of Noah has been proven to be amenable to rational treatment."

The simple fact in the case is that there is a very small number of persons who could not reform if they wished and determined to do so. This small number are certainly diseased.

The others when not drunk are in a normal condition, except that, like other vicious persons, their wills are weak in the line of their desires. When St. Paul said, "Drunkards shall not inherit the kingdom of God," he was not speaking against a *disease* that the poor unfortunate could not help, and for which—Dr. Keeley not having arrived in the universe—there was no *cure*, but against a sin in the sight of God; a work of the flesh, placed by him in the very worst possible company:

"Now the works of the flesh are manifest, which are these, adultery, fornication, uncleanness, lasciviousness, idolatry, witchcraft, hatred, variance, emulations, wrath, strife, seditions, heresies, envying, murders, *drunkenness*, *revelings*, and such like."

One of the most intelligent of the Keeley graduates, a lawyer of rank, exclaims: "What does it profit to cure the body and not the soul? I believe that the Keeley Cure can be used rightfully in connection with mission work, and that a man, while he is taking the cure can be

easily led to our Lord for the greater cure. We are using it in our work. We use it as we would any other medicine. Were it not for its great cost we could do more good, perhaps, than we are doing. I do not approve of the indiscriminate use of the cure. We only use it where there is a sincere desire to lead a sinless life as well as a sober one."

Another graduate writes us that the Keeley Institutes, generally speaking, are pervaded by a spirit of indifference, and in some cases of enmity, to the Church and religion, losing no chance to denounce both as valueless touching inebriety; that many of them claim that the Keeley League is what men should join; that it is worth more to them than ten churches would be.

One of our correspondents, who has had personal experience in his own family in the reformation of a relative, and who has often visited Dwight, informs us exactly what the treatment proposes to do for the patient, and what it does not:

"It does not propose to act as a preventive, in the sense that it renders it impossible for the one treated to go back to his evil way and contract again the disease or the craving appetite from which he has been cured, if he so inclines. It does not produce a dislike for liquor, or cause such disgust at its presence, or nausea if tasted, that relapse to the craving is impossible. It only professes to remove the disease caused by alcohol, and the unnatural craving for it which denotes the diseased condition, so that the one treated no longer finds need of the stimulant in his system, and no craving for it which causes suffering if it be not gratified. In other words, it proposes to cure the abnormal appetite, and to restore the victim of it to the condition he was in before he contracted the appetite for drink. It leaves him without any more necessity to drink than was upon him before he ever indulged; and yet just as free to drink, and as capable of contracting the habit and the appetite, as if he had never drank or never taken the treatment. It professes this, and in my humble judgment it does it, and does in almost every instance, and without producing any physical or mental ill result."

It would be well if this were more widely advertised, and some of the publications sent out by the Keeley Institutes corrected to agree with it. Many of the graduates declare that "the appetite has been entirely destroyed," and some of them say that they have "an absolute aversion to liquor." Under the influence of this, numbers have gone into temptation and have fallen. Occasionally such statements as this appear in the advertisements of institutes:

"It is not uncommonly the case that the effect of the treatment is to bring about an actual aversion for liquor; but this is not by any means essential to the success of the treatment.

"That having been accomplished, it no longer requires any effort of the will power, but simply the exercise of the ordinary reasoning faculties, to abstain entirely from the use of liquor."

The last paragraph in the foregoing statement is extremely dangerous, and shows little understanding of the purely mental tendencies, apart from the physical effects, of any habit long continued.

The secretary of one of the chief Keeley Clubs, writing us a respectful letter, reveals the extravagance of the view that ordinarily prevails among representatives of the movement, when he says:

"We, as Keeley men, know that drunkenness is a disease which can only be cured by scientific treatment. The clergy, as a rule (there are noble and notable exceptions), insist inebriety is a vice, to be overcome by exercise of the will, prayer, and penitence. We hold that a sick man should be cured by the doctor before the clergyman should step in. As long as this indifference exists the clergy are not likely to be well-informed on Keeley matters."

CONCLUSIONS.

That a large number of persons have been reformed in connection with the Keeley agencies, and have remained sober and totally abstinent for many years, bringing happiness to homes that had known the meaning of the word for a long time only by a recollection, we have no doubt.

We believe that the number permanently reformed is not quite so large as our table of statistics shows. Private correspondence has brought to our notice many cases where they had been sober for the period of nine months and returned to drinking, sometimes after one, two, or three years of abstinence.

Some of the graduates think that we should have made the length of time at least a year, affirming that genuine dipsomaniacs often keep sober for that length of time between their periodic outbreaks.

Also, we believe that some scandal is brought upon the treatment by numbers of persons who take it merely to please their friends, who have no moral abhorrence of the life of the drunkard, but have been persuaded to go. These afterward resumed their associations, and the Keeley Cure having done nothing for them, except to put them relatively to resuming drinking where they were before, they, apart from the mental associations, go back to their former lives with avidity.

Yet we believe that many who never would have reformed do so with the aid of this system. If thirty per cent. or twenty-five per cent. are thus reformed, we should not wish to be placed in the position of deterring any from trying it.

While there are many fake cures in the country besides the Keeley system, there are several systems as worthy of confidence as that, and subject to the same sort of limitations. Some of them do a flourishing business, using remedies that are apparently substantially the same, paying no royalty upon their medicines, and giving treatment at less cost.

How are the results brought about?

Many elements are involved: the personality of Dr. Keeley; the surroundings; the testimony of cured patients; the amazing free advertising; the power of mystery. Seventy-five years ago a medal was passed from man to man which produced such an impression when worn over the heart as to make many believe they could never touch liquor again.

The psychological influence of the positive statements of what the remedies will do is great. The requirement that a person before going there must wish to be cured gives him an excellent start. The fact that many who go there never would have gone except as a last desperate hope also has a favorable influence.

The celebrations, the Keeley leagues, the organization, and all those arrangements which enable one man to lean against another, and which have an effect similar to formation in military companies in the time of battle, are not to be forgotten.

It has been said by some that if Dr. Keeley were to reveal his remedy it would lose its efficiency. No doubt in that case it would lose some of its charm. But there is no reason to suppose that he is not using a system of medicines adapted to help the drunkard over the crisis and build him up.

Had we a drunkard among our personal friends to-day we should first seek to reform him by moral, intellectual, and religious means, appealing to his moral sense, applying every possible enticement. We should endeavor to bring him to a deep consciousness of sin, as well as of depravity, and a soul-harrowing repentance. And if we could induce him to become a true and earnest Christian, we should endeavor to fortify his resolution and conserve his experience by persuading him to an extraordinary devotion to secret, family, and public worship. If we took him to any reformatory, it would be to one where spiritual influences were most conspicuous.

This is upon the assumption that we were satisfied that he wished to reform, and that he felt himself a sinner for yielding to his vicious inclinations, and upon the further assumption that we did not believe him to be a diseased man, requiring any special physical treatment. Should we fail, we should try to induce him to go to a Keeley Institute, after carefully inquiring into the moral character of its manager, so as to surround him with the best possible influences. We would try to induce him to submit to this mysterious process, or any other that could produce witnesses to its efficiency, whether understanding it or not.

A helpless drunkard cannot be made worse by any process that men or devils ever invented; and if made better, a multitude of loathsomenesses, vices and sins may be covered, a soul and body may be saved from death, and peace and hope brought to breaking hearts.

But we should not trust the Keeley Cure alone, and to every graduate of a cure that reads these remarks we solemnly say that neither God by His Spirit nor man by his science will destroy the susceptibility of being stimulated by alcohol. The nerves, the blood vessels, and the nerve cells are all there, and the man who has taken the Keeley Cure can never safely forget that these words apply to him: "Let him that thinketh he standeth take heed lest he fall."

About fifty per cent. have relapsed.

As with the passion for drink, so with the constitutional animal passions. They must ever be restrained by will, sustained by moral principle, divine help, and the avoidance of temptation. As a man who never drank and who has no hereditary tendency may become a drunkard, so a Keeley-cured man may become a drunkard.

We believe also that there are—both in this country and in England—institutions based upon moral treatment, total abstinence, and spiritual helps, the average results of which in producing reformation, without treating the case as one of physical disease at all, are as great in number as those produced by Keeley Cures, and equal at least to them in permanency, with the inestimable advantage of sending the reformed man away with a will re-established, manhood developed and a Christian life well begun.

SOCIETY REPORTS.

TENNESSEE STATE MEDICAL SOCIETY.

(*Continued.*)

S. T. HARDISON, M.D., Lewisburg, read a paper entitled

PUERPERAL ECLAMPSIA.

See page 725.

DISCUSSION.

DR. J. A. CROOK, Jackson: One or two points as to the treatment I would like to bring out. In sthenic cases, the doctor recommends bleeding. I do not believe bleeding is called for under any circumstances. It is plain to any who attends a parturient woman, that before she gets through labor there must be the loss of considerable blood. This sanguinous discharge will be kept up for several days; a drainage and leakage upon her system which will tend to draw her down. Further, the process of lactation will have to be kept up; which also will be a drain upon her system. Every favorable indication accomplished at the time by blood letting, can be accomplished by chloroform or chloral or other remedies. No one, so long as you keep them anæsthetized, can have a convulsion. The convulsive fit must occur during the reaction, or when consciousness is restored from the anæsthesia. Hence, although I have had those of strong, full, robust, healthy character, yet I have never had a case not relieved in the way I have mentioned. I think Dr. Happle's view of bleeding for pneumonia is applicable here—if I should find a case where bleeding would do good, I would bleed, but I have never found such a case.

I have never used veratrum viride, but one of my associates has told me that Norwood's veratum viride is an absolute specific. I think it is nearly ten years since he told me that, and, in the last few months, he related case after case where he used five or ten drops—but I doubt that he did use quite ten drops—and in every instance he had relieved the case almost with the first dose. Some of you, who were present at the meeting of the Western Tennessee Association, will remember the subject discussed there, and our worthy president claimed he had found veratrum viride, in ten drop doses, to relieve the condition almost immediately. I wish to enter my protest against bleeding a patient who has to be bled, at any rate before she gets through the process of nature.

DR. T. K. POWELL, Danceyville: I am feeble and don't like to talk. I wish, however, to differ from my friend Dr. Cook, and to endorse everything in favor of bleeding. I know he is an old man with experience and should know about these things, but I know the division of the condition into two separate conditions, the sthenic and asthenic is correct. I read a paper before the society a few days ago, in which I took the same position. That we should never resort to blood-letting, I

think, is an erroneous idea. When there is a flow of blood producing an effect upon the brain, I think nothing has so good effect as the old-time practice of our physicians of forty years ago, of bleeding immediately as a prophylactic measure. If necessary, it would be well to bleed two or three times before the woman is confined; and in the cases in which you follow up blood-letting before the woman is confined, frequently you may avoid these convulsions during confinement.

The use or veratrum viride is also valuable. If you give chloroform in these cases, which I always do, you will find it necessary to keep the patient under the anæsthetic all the time. The bleeding has a more permanent effect and the veratrum has a more permanent effect, but the chloroform, which we always give, does not have a permanent effect. I have kept women under the influence of an anæsthetic all night to avoid convulsions.

Of course, when the patient is in position to be delivered by forceps or by turning, we have to resort to that Where the head is down on the perineum, I find the short forceps much more convenient than the long instrument. I have forceps which I use without even moving the woman. Where the action of the uterus has stopped and the head is down on the perineum, it is well to use the forceps.

I avoid these cases as much as possible by the prophylactic treatment, but when it is necessary I think the treatment suggested is proper and best.

Dr. W. A. H. Coop, Nashville: I consider this condition as that of hemorrhagic infarction of the brain, and I do not think that venesection in such a case can be too strongly impressed. No other remedy can have as good effect upon hemorrhagic infarction of the brain as venesection. I use chloroform and veratum viride, but the first thing I do is to anæsthetize the patient and open a vein with my scalpel. My patients have all recovered except one, who had the hemorrhagic infraction, and the brain was totally disorganized, or nearly so, when I saw her.

Dr. J. S. Caine, Nashville: I believe we should pay more attention to the prevention of this condition. Eclampsia is evidently the result of the defective elimination, and autopsies have proved that nearly all cases dying of eclamsia have had an exfoliative nephritis. Examination of the kidneys proves that there has been defective kidney action, and poisonous elements have accumulated in the blood, largely consequent upon this kidney condition, which, acting upon the convulsive centers, produces the condition of convulsion, or eclamasia.

We can generally anticipate it. While there are certain cases in which eclampsia occurs without any warning or indications which point to it, as the general rule the danger signal is held out if we look for it; and, usually taking the patient in time, we can guard against the convulsions.

Now as to the line of treatment to prevent this complication. When we discover the symptoms of edema and headache, and that class of symptoms which generally precede the eclampsia, if we are not satisfied that it is this condition, an examination of the urine will usually show defective kidney action; the chemical examination of the urine will show albumen, or the miscroscopic examination will show caste—both evidene of the exfoliative condition. Our treatment, then, is calomel followed by salines, thereby reducing the blood pressure and encouraging the elimination of poisons, which, acting upon the convulsive centers, would later on produce eclampsia.

If this precaution is taken in time, we will have no eclampsia; but if it is not taken and we are ushered into the presence of a case of eclampsia, then we have the two conditions described by the essayist—one, in the plethoric primipara; the other in those cases of adynamic females—and we have to treat them much as the doctor has indicated.

I believe in blood-letting in those cases. What are we to combat? In these cases we have the centers flooded with the excess of blood; we have the brain flooded, not an infarction, probably, but an effusion into the ventricles, to be followed by coma and death. That is the condition we have to fear. Chloroform will palliate; set off for a time the convulsions, but there is nothing curative in it, and shortly you will have effusion into the ventricles of the brain and your patient will drop to a coma which is beyond relief. Now, relieve tension by free blood-letting and you will relieve danger from this source. Chloroform only pal-

liates; chloral only palliates; and veratrum viride only palliates. We must do something to get rid of the poison and also to relieve the pressure. Blood-letting does both. After you have relieved the blood pressure, you can resort to chloral and that line of treatment.

Dr. J. B. Neil, Nashville: I heartily endorse the paper because of the truth that is contained in it. I had the honor, before moving to the city, to be associated with Dr. Hardison in practicing for fourteen years. I believe during that time he and I had more cases of puerperal eclampsia to contend with than any other two medical men in this section of the country, and I know the paper written and read before this society is based upon large experience.

I heartily endorse what Dr. Coop and Dr. Cain have said in regard to blood-letting. I think it is the sheet anchor in the treatment of eclampsia. I never went to a case of eclampsia that I did not open a vein. Never. And without egotism I can say I have lost but one case of eclampsia, and I believe she would not have died had I been able to remain with her. In that case I severed the temporal artery, because I could not stay with her and believed that was to be her salvation. But I believe the brain was already so full of blood that she could not have recovered anyway.

The action of veratrum viride is temporary. Dr. Crook speaks of giving six, eight or ten drops of veratrum viride. Why we had reported here in the academy, a case where a man gave a teaspoonful with good effect. He asked me my opinion, and I said the veratrum viride was either very poor, or he had an extraordinary patient.

Dr. T. J. Happel, Trenton: I believe it is a discredit for any gentlemen in the medical profession, to have a case of puerperal eclampsia in practice. I want to go upon record upon that point. I make the statement for the reason that if a physician keeps well posted upon all the cases he is to treat, he can prevent puerperal eclampsia. I lay down that proposition after twenty years experience.

The course Dr. Cain speaks of is the line upon which to treat these cases. See that all the secretions are in proper condition. Don't wait until your attention is called to a patient. Don't wait until she has headache, and the feet and face are swelling. Find out as to the patient's condition, and keep her posted as to the course to pursue. Keep all the secretions in the proper state and there will be no puerperal convulsions. We may have nervous shock, a nervous explosion during labor, in the case of a primipara, which you can very easily control with chloroform or chloral. I do not believe, however, that such can properly be called a puerperal convulsion.

But there are cases in which we are called to see in this condition, a patient with whom we have had nothing to do. Of course we are not to blame for these.

As to the curative treatment. I will not go to the extent I did in pneumonia, and say I never saw cases of puerperal convulsions which needed bleeding, for I have, and I have bled them. They were not, however, I wish you to understand, my cases. The last case of puerperal convulsions I had anything to do with, I treated with pilocarpine alone, and a hypodermic injection gave relief. There was a slight convulsion after the first hypodermic, but none after the second. I get the same effect from the use of this that you will from blood-letting. The secretions are poured off and the patient is relieved—the patient is depleted that way. You accomplish what under ordinary circumstances you would accomplish with bleeding. Therefore, try pilocarpine, and, if that does not do, bleed. I also use chloroform, chloral and veratrum viride.

As to the case Dr. Neil referred to, where a party gave a teaspoonful-dose of veratrum viride, the stomach evidently did not take it up.

Dr. Neil: It was used hypodermically.

Dr. Happel: Then, I cannot see why it acted as it did. Of course, the proper way to use such remedies is hypodermically.

Dr. W. D. Haggard, Nashville: I am of the same opinion as Dr. Happel, that it is no credit for a man to have a case of puerperal eclampsia. I believe it is preventable in the main. As pointed out by Dr. Cain, we have more or less nephritis and albuminuria. What are the indications to be met? The indications are to keep the kidneys performing their functions and to keep the bowels well open, and that with saline cathartics.

I had the pleasure of spending a winter

in New York, where I met Dr. Fordyce Barker and learned from him an important lesson and I could not have learned from a more eloquent and distinguished man, nor one who has done more for the science of obstetrics. That lesson was to begin early, in the later months of pregnancy, and with saline cathartics get the bowels open and keep them acting well, and above all else to keep the kidney acting well. Gentlemen, I am no routinist, but Dr. Barker gave me a prescription, as follows:

Sulphate of magnesia.....	Equal parts.
Carbonate of magnesia.....	
Sublimed sulphur.....	
Cream of tarter.....	

Dose. One tablespoonful from one to two times per diem, as required, to keep the bowels well opened, which keeps the bowels open and altogether acts so well that I have stuck to it. If you keep the kidneys and bowels thoroughly on the alert, you are not very apt to have the conditions which precede eclampsia.

Dr. J. D. Plunkett, Nashville: As to the several statements that it is not necessary, and that it is to the discredit of the medical men to have a case of puerperal eclampsia. Whether there is a Bright's disease, or a kidney complication of pregnancy has been thoroughly established or not is a question open for further investigation, but we do know that the patients we are called to see may be divided into three classes: First, those whom we have charge of from the earliest months of their pregnancy until that period is ended; second, our care beginning later, say at the six or seventh months on; and third, those that we are first called to see within a few days of labor. If we are called to see a patient, we are engaged to attend during pregnancy and confinement, it is well always to examine the urine. If called early, and if you discover the presence of albuminuria; if you suspect a kidney of pregnancy; if you suspect a Bright's disease, or anything that will cause puerperal eclampsia, then you may perhaps abort the condition by keeping open the emunctories. But the condition may grow worse and worse, and the patient may develop puerperal eclampsia despite all the means you have used.

Called to see a patient just before she is confined we may not be responsible for the development of puerperal eclampsia, but how often does it occur that we know the constitution and make-up of our patient? We may be called suddenly to see her in confinement. There is nothing whatever in her make-up which points to any form of Bright's disease, and yet, without any warning, as it were a bolt of lightning from a clear sky, twitchings, unconsciousness, convulsions and death supervene; and still some say it is not necessary to have puerperal eclampsia, and it is not to our credit. Well! it is a difficult condition to treat

There is another question, the question of diagnosis. During the course of labor there are several things that can, and will, and do come up. Every convulsion during labor is not puerpal eclampsia. Convulsions may be due to epilepsy, to hysteria, apoplexy, cerebral hemorrhage, cerebral embolism or thrombosis, as well as to puerperal eclampsia. It is not necessary to state the diagnostic points with which all are familiar. In the cases of puerperal eclampsia I have seen, I have taken special care to examine the urine microscopically, and, with the exception of two cases in a series I have had in my own and in the practice of others I have seen, I have found every evidence of kidney disease—tubecasts, blood and hyaline, and puss-cells, and all the manifestations. I am of the opinion, while you may find some casts in a particular specimen of urine you examine microscopically, you may not be able to find the presence of renal disease; you may not be able to find albuminuria.

Dr. J. A. Crook, Jackson: I knew, when I took the position I did, I was going to meet with antagonistic views, and I did it to get the members to think.

Dr. Powell suggests that chloroform, chloral and veratrum viride are merely temporary in their effects. What effect has bleeding more than temporary? Does it aliminate by the kidneys? The discussion has proposed elimination by the different emunctories of the body. Does bleeding do this, or add to the kidney functions whatever? I cannot see that it does.

Another thing is the danger from cerebral engorgement, apoplexy or infarction. What does not chloroform do? What does sleep do? Is not sleep an anæmia of the brain? Does not the chloroform, in the same way, bring about the same result as

you propose to bring about the bleeding? And further, Dr. Powell said chloroform must be kept up. Why! You can give chloroform and chloral until you get your patient thoroughly under influence, and after this I have never had a convulsion.

In reference to the use of pilocarpine, mentioned by Dr. Happel, which would produce free diaphoresis, it seems to me, while you might gain an advantage in one way, you would deprive your patient of the strength she will need later on.

Notwithstanding the cases which have been bled and have gotten well in spite of that fact, I think bleeding has not added to the chances of the case getting well, anything more than would the use of chloroform or chloral and these other remedies.

DR. S. T. HARDISON, Lewisburg, (Closing discussion): I tried very hard to show two distinct classes of cases, and I have never for a moment thought of bleeding a patient with defective elimination from the kidney. We have some cases we can explain better in another way than ascribing them to a reflex nervous condition. These are the plethoric cases, I believe Dr. Plunkett had two cases in which there was no evidence of diseased urine.

I want to reply to the point of the innumerable kinds of convulsions presented. It is true there are many kinds of convulsions, but it is strongly probable that convulsions occurring during pregnancy are due to puerperal eclampsia.

I believe Dr. Crook claims we will need all the blood later on. Usually, after the delivery you do not have the convulsions. When we do have subsequent convulsions it is because there has been very little loss of blood and therefore we still have the full plethoric condition. The blood which Dr. Crook expects to be lost later on, may be a good reason for delaying bleeding—if the loss occurs.

I think Dr. Happel's remark is true, that it is not a credit to have cases of puerperal eclampsia. I would always rather it would happen, as did his, in the practice of some brother. I believe if we were up on preventive measures we would be able to get rid of the trouble. A large per cent. of my patients have not come under my care until I was called to attend them in labor. Sometimes the eclamptic seizure is the first thing that greets me upon entering the room. Of course, in such cases I am in no way responsible for the advent of this condition.

As to the cases due to sepsis. I think it requires considerable care to guide a patient with tube-casts and albuminuria, so convulsions will not supervene.

I notice Dr. Happel said he would try the pilocarpine and if it did not succeed he would bleed, which carries to my mind the belief he has more confidence in bleeding than in the pilocarpine.

As to large doses of veratrum viride. I tried to bring out in my paper the point that there is an increased tolerance in parturient patients for veratrum viride. By repeating the ten drop doses frequently, we do not have the symptoms that show themselves in other instances. I do not know why this is true, but with my limited experience in parturient patients I have never been disappointed in the use of veratrum viride as a remedy, and have learned to use it in large doses.

T. J. HAPPEL, M.D., Trenton, presented a paper on

THE OPIUM CURSE AND A PREVENTIVE.

(See page 727.)

DISCUSSION.

DR. J. B. NEIL, Nashville: I regard the paper of Dr. Happel as one of the best that has been read before this society. I endorse what he says on the point of transmissibility from parent to child. I firmly believe it is transmissible from parent to child as a condition of nervousness. If only the man or the woman using the drug suffered, the evil would not be so great, but the essayist has certainly brought before us case after case demonstrating the fact, which has been demonstrated before, that the condition is transmissible from parant to child.

DR. T. K. POWELL, Danceyville: One feature of the paper I object to. The essayist recommends that people who were addicted to drink and to using opium should be put in an asylum and kept there until cured. The question arises in my mind, as to which is the better, to let these persons go ahead and drink and use opium until they die, or to let the other nine-tenths of the people pay taxes to support them. I think it is wrong to encourage the erection of so many institutions. I think there is a false sentiment

along that line, and one of the worst things we have done in Tennessee was to do away with the system of correct work.

Whilst Dr. Happel is perfectly correct in saying we should be guarded in the use of opium, it should not be forgotten that we can go to the other extreme and encourage the use of too little. I am a believer in the use of opium under proper circumstances, but I think Dr. Happel is correct, and we should attempt to overcome the indiscriminate use of it. But deliver me from being taxed.

Dr. W. L. Scott Dixon: I have before my mind, a patient whom I attended in confinement about sixteen months ago. The mother said she could not take twenty grains of morphine three times a day, and attend to her regular business. Twenty-four hours after delivery of the child they sent for me, saying they couldn't do anything with the child. I asked if they had given it anything and they said: Yes! they gave it thirty drops of laudanum after I left, but couldn't do anything with it. The child is as restless and nervous as it can be, and its whole life has been spent in nervousness, besides it being under the influence of opium.

I hope this subject will make a greater impression on the public than ever before.

Dr. Hardison, Lewisburg: I wish to dissent from Dr. Happel on two essential things. I take it from his paper, that he does not hold the profession guilty to any great degree. In that I differ from him. I believe it is not intentional, however. But I know there is a careles habit among the profession to give opium and morphine in trivial diseases. The patient has the prescription refilled and becomes a confirmed opium or morphine user before he is stopped. I believe, if we are to get to the bottom of this question, we will have to be very careful to exclude that handy prescription for morphine when we want to get rid of a patient with pain. I believe the druggists over the land are, in the main, good honest men; but in the law suggested by Dr. Happel they do not believe, from the manner we are handling the drug, that they are justified in considering it a poison. I believe we should say to the druggists in every city and village and hamlet in this State: "Here is the law. You are not permitted to sell the drug without a prescription." When we are able to impress that duty upon them, we will have there co-operation. I do not believe pharmacists and druggists, as a class, would begin to disseminate this habit for the little sum of money they receive. Then, I think we should have the facts spread by the Legislature before the people, that this is a dangerous drug. In every town and community and every country cross-roads store, morphine and opium are being sold, and you can pick out a number of families in every community who are taking opium or morphine daily. The morphine-user always thinks he knows how every evil can be cured.

One other suggestion, and it is rather difficult to make, but there are too many doctors taking morphine, according to my limited experience. We are very good in theory, but not, I fear, always so in practice. If it is known that for every little cold, and for the hundred times you have had the *grip* in the last year, you have taken morphine, your patients will do the same thing. There is hardly a physician in this society but has treated a neighboring physician who has said he was taking morphine. The profession should raise a note of warning. If it is not right, every druggist should be responsible, and that would have a curtailing influence in the sale of this drug. If every person using it must have his name written down every time he purchases the drug, that fact will have a tendency to stop the use of the nacotic.

Dr. Lewis: I have had a limited experience in the treatment of morphinism and I have come to the conclusion that the habit is transmitted, as much so as the habitual use of alcoholics. We classify alcoholism as dipsomania—a form of insanity. I am thoroughly convinced morphinism is as much, if not more, a form of insanity.

As to the treatment of those cases. The morphine patient, first, has transmitted to him a peculiar neurosis. That peculiar nervous system requires a certain amount of morphine to elevate it to its normal tone; but, in taking away the morphine, you will, invariably, find these patients take more morphine than is absolutely necessary. I always, in taking the morphia from the patient, strike a ratio of a fourth or a third of the amount they are taking when they enter the hospital. I have received patients taking as much as ten or twelve grains per day, and brought

them down immediately, to three or three and a half grains per day. I do this by the substitution of strychnia for the amount of morphia I have taken away from them. I have received a patient taking twelve or thirteen grains a day, and brought him down to three grains per day, by the substitution of two or more subcutaneous injections of a third of a grain of strychnia. I can, in this way, quite readily take away the morphia. The strychnia seems to take the place of the morphia wonderfully, and to give a normal tone to the nervous system.

These patients are in the habit of increasing the amount of the morphia. A certain amount of morphine is required to produce a normal tone of the nervous system, and they take the excess to enjoy the pleasant dreams and thoughts that ensue. Their flow of ideas is quickened.

If you give them only enough to produce the normal tone, they will have none of these pleasant dreams or thoughts, only the normal condition.

Question:—What do you think of Keeley?

Answer:—I don't agree with Keeley. I have two or three cases now that Keeley has been working on. You ought to see their arms, from the wrist to the shoulder.

Dr. T. J. Happel, Trenton, (Closing discussion): I have written a condensed paper and not included everything I would like to have touched. In regard to Dr. Powell, he and I are, the one on top and the other on the bottom, in everything, figuratively speaking. He objects to the idea of a little money being expended for this, and thinks we should let these people go on and kill themselves. If they would do only that, it would be all right; but they don't do that.

If you have a patient leading a life which will cause misery to the children, send the patient to the asylum and have her cured. This is a subject not to be measured with dollars and cents, although I know the tendency is to measure everything that way.

It is a matter of personal liberty to a certain extent, but it affects the community. It affects unborn children, we should not be responsible for the sins of the mother and father. The law throws a cloak around the money of the child, and why should the mother or father of that child unborn, be allowed to blight the life of the child? It would be better to put the father or mother in the asylum. This will cost in the end very little in dollars and cents. In many cases they will never return to the degrading habit. Send them there; some relative will be interested enough to prefer the charge. I have seen families where it would be the greatest relief in the world to get the parents in an asylum. Don't put it in the scale with dollars and cents.

As to the profession being guilty of helping to spread this habit. I grant the profession is accidentally guilty. This paper is written to influence physicians to avoid as much as possible giving opium. I think the paper set forth, that the only cases where we are justified in using it are, such as cancer, where the patient is suffering untold agony. Then let the patient's pain be relieved. I believe our law should be so changed as to forbid any man practicing medicine who makes a sot of himself with drink or by using morphine.

Patients can be kept in the jails and treated there just as well as by erecting asylums, but we have no legal right to do that.

That is what I want to get. We should get the legal right to do this, for other rights should be considered than those of the individual.

The paper was not intended to include chloral or other drug habits, but Dr. Baxter's position, in reference to the proprietary medicines, was well taken.

I did not say in the country generally, opium is not used, but I said this, in the country the female sex does not take to the use of alcohol. Women in the country villages are not using liquor. In the cities they use whiskey as well as opium. In the country they use opium to a great extent, perhaps in as large proportion as in the cities.

As to treatment. My paper did not propose any. It is entitled, "The Opium Curse and a Preventive." I did not propose to enter into the treatment, because it would take a book to discuss the treatment. But the best treatment is to put the patients in a jail or asylum, take charge of them as you would any other lunatic and break them of the habit there. When broken, you will find they will not go back to it as the hog to his wallowing in the mire.

CURRENT LITERATURE REVIEWED.

IN CHARGE OF ELLISON J. MORRIS, M.D., AND SAMUEL M. WILSON, M.D.

JOURNAL OF CUTANEOUS AND GENITO-URINARY DISEASES.

Dr. W. W. Bowes describes

A New Varicocele Needle

by the use of which varicocele may be treated by ligature without danger of including the dartos in the ligature or of piercing the veins with the needle.

Dr. J. A. Bloom reports the

Treatment of a Case of Epithelioma with Lactic Acid.

The patient was a feeble man, sixty-five years old, who had an epithelioma of one cheek which had taken a rapid growth after a slow increase for five or six years.

The author thought the case unsuited to radical operation and applied Moorhof's treatment of lactic acid. Once daily a paste of pure lactic and salicic acids about fifty or sixty per cent. was applied.

This caused not much pain and the strength was increased in about a week.

Six or seven weeks later there remained only a clean, smooth, non-elevated cicatrix and the author thinks the failure of others to achieve the same result is owing to want of thoroughness in making the applications.

Dr. Gardner W. Allen gives some remarks on the

Treatment of Cystitis.

Most of the cases recorded were gonorrhœa and of the usual type—frequent and usually painful micturition with more or less retention. The best results were obtained by benzoate of sodium internally accompanied by irrigation of the bladder. A saturated solution of boric acid is very satisfactory for this purpose in many cases, but when something more than mere cleansing is necessary instillations of a solution of nitrate of silver or of permanganate of potash are preferable. The author uses ten or fifteen minims of a solution of nitrate of silver one per cent. or weaker, and if this does not seem beneficial he substitutes a solution of one to four thousand or five thousand permanganate injecting five ounces and allowing it to run slowly out, then five ounces more, etc., until an unchanged solution runs out. Two or three ounces are now injected and allowed to remain, the secretion of urine decomposing it before any injury can result. This treatment is usually efficient. Injections are made at intervals of four or six days and the strength of the solution gradually raised to one to two thousand. The use of a large sound before injecting is advised.

BUFFALO MEDICAL AND SURGICAL JOURNAL.

Dr. Willis E. Ford writes of

The Dangers of the Uterine Tampon.

The author favors dilatation and curettement of the uterus for endometritis, etc., and thinks he has cured an encysted salpingitis by this means followed by a gauze tampon, but in most cases does not favor a tampon of any kind, thinking the gauze acts as a seive rather than as a drain and retains the substances we are most desirous to get rid of. When dilatation is to be performed we should first assure ourselves that there are no adhesions or malpositions, and if these exist they must be relieved before we dilate. When these directions are ignored serious injury is apt to follow.

Dr. Frank J. Thornbury is quoted as reporting a

New Micro-organism Found in Pork.

It belongs to the saccharomyces and is pathogenic, killing white mice and rats within twenty-four hours after injection.

IN THE AMERICAN MEDICO SURGICAL BULLETIN

Dr. Frederick A. Lyons has an article on

Gonorrhœa in Women.

The subject is, he thinks, poorly understood even by many good surgeons, and frequently is passed unrecognized on account of an old conviction which should now be given up; that gonorrhœa in women is usually evidenced by vaginitis and that it is the exception to find the urethra involved early in the disease. The author criticises several writers for teaching this theory at the present day, and quotes cases where he has found the gonococcus in the urethra, vulvo-vaginal glands and follicles and in the cervical glands when there was no vaginitis and when there had been none.

Failure to recognize this leads to wrong treatment and perhaps to the establishment of serious pelvic disease.

JOURNAL OF NERVOUS AND MENTAL DISEASE.

Dr. Wm. F. Drewry writes of

Circular Insanity,

and reports several cases in which the patients had for a varying period a condition of melancholia or depression, followed by another interval of excitement or mania.

His conclusions from personal observation are that circular insanity is a rare but distinct form of mental disease for correct diagnosis of which it is necessary to have a patient under close observation for some time. There is probably no true period of convalescence between the attacks. The excitement may vary in intensity from a simple feeling of self-satisfaction to maniacal excitement, but the incoherence and confusion are not so marked as in ordinary mania, and the depression may vary from simple torpor to obstinate melancholia with suicidal tendencies. There may or may not be delusions, hallucinations, etc.

There is no distinctive cause for the affection, for in one case it seemed hereditary, in another due to fever, in a third to syphilis. The symptoms may be temporarily improved but no system of treatment has yet seemed to give permanent benefit.

Dr. J. Madison Taylor reports a case of

Epilepsy Cured by Operation.

The operation was performed by Dr. T. G. Morton seven years ago and the case was reported five years ago—the further report given now because no convulsion has since occurred. A healthy boy about three years of age fell fifteen or eighteen feet fracturing his skull at the right parietal prominence. No convulsion ensued and the wound healed promptly. Occasional slight spasms limited to the left arm and beginning with an aura felt in the forefinger and thumb soon began. These appeared to be outgrown until at ten years of age when much excited by a problem at school the aura was again felt and followed by flexion of the fingers, wrist and elbow, bringing the clenched hand into the axilla. The left side of the mouth now became drawn down and the left leg became somewhat the same condition as the arm and the boy fell. Attacks usually induced by excitement now occurred once or twice every month and were preceded by a minute or a minute and a half by the aura. The patient or his parents could by unlocking the fingers and vigorously rubbing the palm of the affected hand usually prevent the development of the attack. Consciousness was not lost during an attack and to check the convulsions it was necessary for the patient to turn on the left side as they seemed to continue while he lay on the right.

It was found that pressure on the seat of the old injury gave a sickening sensation and if continued led to convulsions. An operation was therefore performed by Dr. Morton and some pointed masses of bone which pressed on the cortex were removed. No particles had penetrated the substance. Recovery was uninterrupted and the only semblance of a return was a fall followed by severe pain for some hours caused by a companion throwing a ball of wet paper and striking on the seat of injury.

Dr. Philip Meirowitz reports a

Case of Tetanus.

A healthy schoolboy of good antecedents, twelve years old, was seen three weeks after a severe beating in which the patient had been stood on his head and struck on the back. No bruise nor break of the skin was to be seen. One week later the boy had a splinter run into his hand and after its extraction the wound readily healed. One week later the boy complained of languor, stiffness of joints, inability to open the jaws as wide as usual, but continued to play as usual. The following morning he was found with limbs rigid, jaws locked, conscious, and without fever, convulsions, or headache.

The boy was treated for five days without improvement and was seen by the author on the sixth, at which time there was risus sardonicus, general rigidity of the limbs, and well-marked opesthotonos, the pupils were of medium size and reacted to light, and the respiring, while usually regular, was sometimes of the Cheyne Stokes variety. At times an increased tonicity of the affected muscles was noted to appear and in a few minutes relax again. At all times consciousness was complete, but pain which was scarcely noticed at first became so severe as to cause the patient to beg for relief. The following day the patient died in coma, the heart beats being imperceptible five or six minutes before the last deep inspiration was noticed.

When called to see the case the author attempted to give relief with chloroform, but even a few inspirations caused Cheyne Stokes breathing and had to be stopped. Hydrochlorate of hyoschyamine, morphine and curare were all unsuccessful and then an enema of milk and whiskey with thirty grains of chloral was given with some good effect, but the patient died in the sleep induced by another given six hours later. In the opinion of the writer the indications in a case like this are to calm the nervous system by narcotics freely used, and to sustain the strength by nutritive enemata, and he notes the neglect of this treatment in this case. The case is etiologically interesting also, the question arising whether it originated in the beating, the poison introduced with the splinter or in some different unrecognized manner.

PERISCOPE.

IN CHARGE OF WM. E. PARKE, A.M., M.D.

SURGERY.

Treatment of Urethritis.

Writers never seem to tire of giving their experience in the treatment of urethritis. Dr. Ramon Guiteras, in the *Medical News*, is inclined to conservative methods and does not lay much stress on the gonococcus and endoscope. He concludes:

1. That it is impossible to treat urethritis according to any given rule at the present day, a successful method not as yet having been discovered.

2. That specialists are much better able to treat it successfully than the general physician, and to go further, that a patient receives better treatment from a specialist in a dispensary than from a general physician in private.

3. That injections checking all discharge or reducing it to a moisture about the meatus, such as those of mercuric chloride, potassium permanganate, and silver nitrate, are the most successful means of treating a fresh attack, and that of these silver nitrate is one upon which most reliance can be placed.

4. That in all cases the patient should be treated conservatively, and the treatment should be modified according to the symptoms.

Propagation of Affections of the Tympanum to the Brain by the Way of the Carotid Canal.

Koerner demonstrates anew the fact that canaliculi conveying nutrient vessels from the carotid canal to the mucous membrane of the drum cavity may become the passageway of microbes of otorrhea either with or without caries, and cause arteritis, lymphangitis, phlebitis of the venous plexuses, with participation of the lateral sinus, and even thrombosis of the carotid artery and consecutive cerebral embolism. He cites cases in which the external tunic of the artery was infiltrated with tuberculous granulations, and admits the possibility of tuberculous meningitis having its origin in this way in bacillary otitis media.—*Archives of Otology.*

The Pulse in Clinical Surgery.

The *Revue Internationale de Medicine et de Chirurgie Practiques* for March 10th contains a review of a work by M. Francois Bertonnier on this subject. In this interesting work, says the writer, the author first recalls Marey's statement as follows: "The pulse is the sensation of sudden swelling felt by the finger which palpates an artery. The blood-vessel that allows itself to be depressed becomes suddenly hard each time that a systole of the heart increases the arterial tension." Bertonnier then considers this physiological phenomenon with regard to its frequency, its power and its rhythm. In two chapters he explains the connection between the pulse and the temperature, also the usefulness of examining the pulse in cases of severe hemorrhage. His principal conclusions are the following: 1. The discordance of the two curves, that of the temperature and that of the pulse, is often an indication of a serious condition. 2. In grave hemorrhage the great depression of the pulse that accompanies it has sufficed occasionally to indicate the true diagnosis. 3. In traumatic shock, or that following an operation the degree of slenderness, of frequency, and of irregularity of the pulse will be the most exact measure of the violence of the shock and of the patient's vital resistance. 4. In traumatic cranio-cerebral lesions extreme slowness of the pulse is a never-varying sign of concussion, of contusion, or cerebral compression. Eventually, its acceleration with elevation of temperature is a sign of meningo-encephalitis. 5. The pulse should often be a guide in surgical interference in traumatic or inflammatory affections of the abdomen. 6. The absence of arterial pulsation at the extremity of a member is a very important sign and calls for a prompt determination. Finally, the pulse, under the influence of chloroform, by its irregularity, intermittence, and arrhythmia, indicates, even better than auscultation of the heart, that the valvular lesions are badly compensated for, and that there is danger in the administration of chloroform.

OBSTETRICS.

Are the Uterine Ends of the Fallopian Tubes Ever Pervious When the Tubes Contains Pus?

Notwithstanding the recent emphatic declaration of one of our most noted gynecologists to the contrary, numerous cases in which tubes are pervious are being reported. Dr. T. J. Watkins, of Chicago, says that while separating the adhesions of a pus tube on the left side he noticed that the tumor suddenly decreased in size without rupture. Fully four drams of pus were forced out through the uterus into the vagina, over the vulva, and onto the operating table. He thinks that this case, however, could not have been relieved by curettement, drainage, massage or galvanism, because, first, the patient had an abscess of the opposite tube and ovary, and, second, because the walls of the left tube were so distended, adherent and thickened as to be incurable by any operation short of an abdominal section.

Dr. F. A. Glasgow, of St. Louis, practices dilating the cervix with sterilized elm tents in these cases saying, "We can gradually slip in tent after tent, first dipping them in glycerine or water for a moment, until the cervix is full. I now place a wad of cotton tied with a string just against the cervix; the tents are cut off to a length which will just permit them to entirely enter the os externum without pressing on the fundus; they have each a short string attached to them. This is kept up for a number of days, the patient being kept in bed. Sometimes the dilation causes pain; often none. If, when the uterine canal is large enough to admit the finger, there is no discharge of pus with relief of the symptoms, I anesthetize and curette. I now pack with gauze and repeat for a number of days. I cannot at present recall a case of tubal distention where I did not get some discharge after packing with gauze or dilating with tents for some time. Very often there is a very offensive watery discharge comes through the packing, even soaking into the bed. Every case is not permanently relieved."

Rectal Examination of Pregnant Women.

W. H. Beckman (*Shurnal akuocherstwa i Shenskich bolesnej*) has tried this method with great success in 100 parturient women, the details of pelvis and cervix being easily made out. The length of the pregnancy and state of the bladder could not be determined in 7 per cent. of the cases, and the fontanelles and sutures could not be felt in 28 per cent., but this was less important, since the position of the fœtus could easily be detected by external examination and especially by auscultation. It was always possible to distinguish the occipital from the frontal portion of the head. The advantage of rectal examination is that infection through the genitals is avoided, the only objection being that sometimes examination through the vagina may become necessary, and that infection may occur through the examining finger,

though the latter is easily disinfected, since the rectum does not contain specific microbes. The author considers rectal examination of great value to midwives, enabling them to determine if the presence of an obstetrician will be necessary. Zweifel's experience in the Leipzig obstetrical clinic showed that students instructed in this method of examination could determine all the necessary details without recourse to vaginal examination. Ries believes that midwives should be forbidden to make examinations through the vagina, as their duty is only to assist at normal births. Kroenig is inclined to permit vaginal examinations only (1) when it is difficult to determine through the rectum what part of the fœtus is presenting, (2) when the midwife is not able to bring about relaxation of the cervix, and (3) when the pains last more than two hours.

Vaginal Injections During Labor.

Hot sublimate or carbolic injections during labor shrivels and contracts the vaginal mucous membrane by contracting the capillaries, removes from it its natural lubricating secretion, thus largely augmenting the friction between the head and the vaginal walls, retarding the progress of labor and necessitating greater powers of expulsion.—*Charlotte Med. Jour.*

Viburnum Prunifolium in Abortion.

Mme. Michailowa (*Meditzinskoje Obozrenije*), after a trial in four cases, states that, contrary to the accepted opinion, this remedy not only does not always prevent abortion, but sometimes even occasions it or, at least, accelerates a miscarriage already commenced. The hæmostatic action of the drug (2 grains—0.12 gramme—in powders four times daily) was constantly observed, but in two cases, after the first day, contraction of the uterus followed, favoring the commenced abortion. In three cases, directly after the administration of a dose, contraction of the external os was observed. The author believes that, although viburnum may occupy a prominent place in the treatment of female diseases, it is not without danger in cases of threatened abortion.

ARMY AND NAVY.

CHANGES IN THE U. S. ARMY FROM APRIL 30, 1895, TO MAY 11, 1895.

Leave of absence for one month and fifteen days, to take effect on or about June 16, 1895, is granted Major William E. Waters, Surgeon, U. S. Army.

The extension of leave of absence on surgeon's certificate of disability, granted Major Washington Matthews, Surgeon, is further extended four months, on surgeon's certificate of disability.

The leave of absence on account of sickness granted Major Clarence Ewen, Assistant Surgeon, is extended three months on account of sickness.

Captain Louis W. Crampton, Assistant Surgeon, will report in person to the President of the Examining Board appointed to meet at Denver, Col., on May 14, 1895, for examination for promotion.

Captain Richard W. Johnson, Assistant Surgeon, is relieved from duty at Washington Barracks, D. C., and ordered to Fort Huachuca, Arizona, for duty, relieving Major Timothy E. Wilcox, Surgeon.

Major Wilcox on being thus relieved is ordered to Fort Schuyler, N. Y., for duty.

NEWS AND MISCELLANY.

Deer Park on the Crest of the Alleghenies.

To those contemplating a trip to the mountains in search of health and pleasure, Deer Park, on the crest of the Allegheny mountains, 3,000 feet above the sea level, offers such varied attractions as a delightful atmosphere during both day and night, pure water, smooth, winding roads through the mountains and valleys, and the most picturesque scenery in the Allegheny range. The hotel is equipped with all adjuncts conducive to the entertainment, pleasure and comfort of its guests.

The surrounding grounds, as well as the hotel, are lighted with electricity. Six miles distant, on the same mountain summit, is Oakland, the twin resort of Deer Park, and equally as well equipped for the entertainment and accommodations of its patrons. Both hotels are upon the main line of the Baltimore and Ohio Railroad, have the advantages of its splendid Vestibuled Limited Express trains between the East and West. Season excursion tickets, good for return passage until October 31, will be placed on sale at greatly reduced rates at all principal ticket offices throughout the country. One-way tickets, reading from St. Louis, Louisville, Cincinnati, Columbus, Chicago, and any point on the B. & O. system to Washington, Baltimore, Philadelphia or New York, or vice versa, are good to stop off at either Deer Park, Mountain Lake Park or Oakland, and the time limit will be extended by agents at either resort upon application, to recover the period of the holder's visit.

The season at these popular resorts commences June 22d.

For full information as to hotel rates, rooms, etc., address George D. DeShields, Manager, Deer Park, or Oakland, Garrett County, Md.

LEPROSY*

A. W. HITT, M.D., INDIA.

What we now recognize as separate and distinct diseases have been described by ancient writers under the term "Leprosy." We are indebted to the Bible for the oldest record of leprosy.

The Bible mentions a person as "a leper, white as snow." This case would not be classified to-day as a case of leprosy, but as *leucoderma*. On the other hand, the Bible gives a very good description of anesthetic or nerve leprosy, in the twelfth chapter of Leviticus.

Many prominent men have died with this loathsome disease. The Talmud says, "The Lord smote Pharoah, King of Egypt, with leprosy. The disease was exceedingly grievous and the King suffered inexpressible agony." In conversation with an intelligent Egyptian, who was well versed in the history of his country, I was told that Rameses IV. was the king referred to.

It was said that Moses had leprosy, and Manetho states that 90,000 leper Jews went out of Egypt with him. Josephus discredits the idea that Moses was thus afflicted.

I belive that Job at one time had leprosy. He speaks of scraping himself with a "potsherd," and says of his sufferings: "When I lie down I say, 'When shall I arise and the night be gone?'" And again, "I am full of tossing to and fro till the dawning of the day, and my flesh is clothed with worms and clouds of dust. My skin is broken and become loathsome." And of his friends, he says, "They abhor me and flee from me, and spare not to spit in my face."

King Uzziah and Naaman, the Syrian captain, also had this loathsome disease.

Robert Bruce, King of Scotland, died of leprosy in 1392.

I mention the above cases to show that it is not a disease limited to the poorer classes only. The rich suffer from it as well as the poor.

The ancients regarded Egypt and the valley of the Nile as the home of leprosy.

Isadore of Seville (A. D. 582) speaks of leprosy being in Spain. During the reign of Louis VIII. (1226 A. D.) there were 2,000 leper asylums in France, while the number of asylums in all Europe was estimated to be 19,000.

Twenty years before Columbus discovered America, there were 112 leper asylums in England.

MacNamara says a leper asylum was established in Canterbury, England, A. D., 1096. Segregation had almost driven it out of England.

Sir J. Y. Simpson gives an interesting account of how lepers were banished from London during the reign of Edward III.

*Read before the Tennessee State Medical Society, April, 1895.

The leper was looked upon as a dead man, and the church performed the solemn ceremonials of the dead over him on the day on which he was separated from his fellow creatures. He was from that time dead to law and legally buried, though still alive and breathing. The priest first went to the house and conducted a part of the ceremony. The leper was sprinkled with holy water and was then led to the church where he was clothed in a funeral pall, and while placed before the altar between two trestles, the Libera was sung and the mass for the dead was celebrated over him. He was then given a special dress, and a pair of clappers so that he could warn the people not to come near him.

This is quite a contrast to what I saw daily in India: men sitting by lepers, eating with them, and dipping up water to drink within a few feet of where lepers stood washing themselves and their dirty loin-cloths. A barber called at our house and after cutting a friend's hair asked me if I wanted to be shaved. I told him "No." He then asked for medicine and when I examined him, I found he had leprosy.

During my travels in various parts of the world, I have found leprosy in almost every place I have visited. I can safely say that no part of the world has escaped this dreadful scourge, save a few of the islands in the ocean. Even Iceland was included in the list as far back as any of our writers can remember. In 1652 a leper asylum was established in that country.

India, China, the Sandwich Islands, and the different districts of Africa suffer most from it.

Some people believe that there are 250,000 lepers in India, while MacNamara, who is one of the leading authorities on leprosy in India, says there are 128,089 in British India. There were 6,614 in the district in which I lived.

China is said to have almost as many lepers as India, but owing to so much of the country being closed to foreigners, it is next to impossible to get or give any correct information.

Dr. Hillerbrand, who has been practicing in the Sandwich Islands since 1851, says that there were doubtful cases as far back as 1848, but the first well-authenticated case was reported in 1859. It was introduced by the Chinese, and as there was no word for it in the Kanaka, the natives called it "Miapake," or Chinese disease. There is now one leper to every thirty healthy natives in these islands. The leper asylum on Molakai in 1890 had 1,159 lepers in it. There are now about 1,500 in this asylum.

Our own fair country has a fair sprinkling of it, there being 522 cases now in America. Only a few weeks since two lepers were discovered in the country above Cincinnati, Ohio.

For quite a long time two types of leprosy have been recognized: the tubercular and the nerve type (generally known as the anesthetic form), which when combined, form a third, known as the mixed type of leprosy. The same bacillus causes both forms.

If the bacillus finds a home and can develop in the corium, we will have as a result, *tubercular* leprosy; but if the bacillus does not attack the corium and reaches the nerves of the extremities and face, we find *nerve* or *anesthetic* leprosy. In other words, I believe that the type of the disease is determined by the channel through which the bacillus enters the body. Should it be deposited in the skin, especially in a weak place, and remain undisturbed, tubercular leprosy would follow.

SYMPTOMS.

Nerve or Anesthetic Leprosy.—Generally the patient has several feverish attacks and the whole constitution seems to be disturbed. This is not always the case, but, generally speaking, among the lower, ill-fed classes, this will hold good. The first symptom which attracts the attention of the patient is a tingling or burning sensation in patches on the different parts of the body. The backs of the hands and the fore-arms are generally the parts which are thus attacked.

Lancinating pains along the course of the nerves are next noticed, and the color of the integument changes. In some cases, it becomes darker; in others, the skin pigment is diminished and the part becomes lighter than the surrounding skin.

Pemphigoid eruptions are commonly noticed. An erythematous rash appears over the affected parts. The pimples vary in size from that of a lentil to a pea. These patches gradually fade and the

epidermis shows a tendency to desquamate after the drying up of the eruption. These spots spread peripherally and begin to fade first in the center. The complete cessation of perspiration from the surface of these spots is very important as a diagnostic point. Pilocarpine will not affect these spots. In some cases these spots are delayed and do not appear until after the disease has been in the system for ten years. The destruction of the nerves disturbs nutrition and the sense of feeling. Soon the most distressing part of the disease shows itself and the extremities and face are mutilated. The nose sinks in and leaves a ghastly looking patient whose face you can never forget. The fingers and toes become crooked and ankylosed. The phalanges either drop off or become absorbed and disappear in this way. The hair drops out in tubercular leprosy, while it becomes white in the anesthetic spots of nerve leprosy and does not always fall.

There is great pain about the eyes, nose, cheeks, mouth and limbs. After months or years of suffering, the pain ceases and anesthesia supervenes. An eye can be cut into at this stage without hurting the patient. The patient's health fails after years of suffering, and he becomes anemic, and visceral complications arise. Amyloid degeneration of the kidneys and liver, with chronic diarrhœa, finally put an end to his suffering and miserable existence.

Tubercular Leprosy—As in the anesthetic form, we find fever and a general breaking down of the constitution in the first stages of tubercular leprosy. When the disease is well advanced, the tubercular or nodular masses on the face, with the greasy, shining appearance, causes the patient to look simply frightful. This is the leonine appearance (leontiasis) as commonly noted by both ancient and modern writers.

If you will pardon me for mentioning elephantiasis here, I will say it seems strange that these two powerful and destructive diseases should be in appearance so much like the two most powerful and destructive animals of the country in which they prevail, that the name "leonasis" from the resemblance to the lion, and "elephantiasis" from the resemblance to the elephant, should be given them. Leprosy, like the king of beasts (the lion), is the king of diseases, and is the most destructive disease known, so far as mutilation is concerned. And as the immensity of the elephant, or, if you will pardon me for using the expression, this great exaggeration of animal life, impresses you on first seeing it, so the immensity or apparent exaggeration of the disease impresses one when he first sees a well developed case of elephantiasis.

Another point which to me is very interesting: Only a short distance from our place, is a town (Ruttenpore) which is noted for two things: first, the great number of cases of elephantiasis; and second, the large "tulahs" or artificial ponds. Ruttenpore was for centuries the capitol of this district, and the native kings or Rajahs had great herds of elephants here. The elephants were washed and bathed in these tanks daily, and the natives now say that every person who bathes in one of these tanks is sure to have elephantiasis; while in the neighboring tanks where no elephants were bathed, the water is pure. If you ask a native some distance from this place, if he has ever visited Ruttenpore, he will, as a rule, reply, "Yes;" and add, "*Ruttenpore admi ha thi pau ka mawfik*," (Ruttenpore men have feet or legs like the elephant). This is the natives' belief about the matter. I leave you to judge as to where there is any connection.

Thin says, "When the parasite has established itself in the skin, the first effect (before there are any changes observable to the eye) is to set free a poison, which produces more or less marked results in different individuals, causing the so-called prodromata or premonitory symptoms of leprosy. After a time the multiplication of the parasite causes a vaso-motor paralysis of the parts in which it grows, producing the exanthem of tubercular leprosy.

"The further development of the bacillus leads to direct changes in the corium itself, causing swelling, thickening, infiltration and discoloration, which vary according to the extent and rapidity with which it grows. This forms the so-called tubercular stage. The breaking down of connective tissue and the destruction of blood vessels produced by this excessive growth of bacilli, lead to ulceration—the ulcerative stage of tubercular leprosy. Finally comes a time, when in most cases, the bacillus leads to leprous deposits in the liver and spleen, and the patient becomes

exhausted by the constant discharge from the ulcers and by visceral complications, to which he eventually succumbs unless, in the meanwhile, he has been suffocated by the leprous growth in the larynx, or has died of some acute intercurrent malady."

PATHOLOGY AND BACTERIOLGY.

The Bacilli Lepræ have been found in the cells of almost all the tissues of the body in persons affected with leprosy, but it is in the cells of the diseased nerves and skin that the bacillus will be discovered in the greatest abundance.

In the early stages of nerve leprosy, the bacilli first grow within the cells forming the sheath of one or more of the nerves, most frequently the ulnar nerve.

The Lepra bacillus resembles that of tubercle; in length it is about one-half to three-fourths the diameter of a human blood corpuscle. The Lepra bacillus multiplies by fission. As it has not been found free in the blood, it is doubtful whether it will live outside the cell wall.

Danielssen and Boeck give a good account of the changes visible to the naked eye. The epidermis is found normal in a section of tubercle which has not softened, and from the slightly firm corium a little viscid fluid can be expressed. The cut surface is granular, yellowish white, and a substance having this color can be squeezed out of it. The subcutaneous tissue is infiltrated and thick, and a lardaceous mass, which is often gelatinous, adheres to the corium. The skin becomes gradually thickened, the tubercle very rarely extending to the subcutaneous tissue, which does not soften with the rest of the tubercle. The vessels and nerves in the diseased tissue become thickened but resume their normal condition on passing into healthy tissue.

About the only difference of consequence, pathologically, between the types of disease is that the nerves are affected in nerve leprosy and the skin in the tubercular leprosy.

DIET.

Almost every article of diet has been accused of causing leprosy. Mr. Jonathan Hutchinson believes that fish will cause it. Lepra bacilli have never been found in fish, either fresh or dried. I, therefore, cannot believe that fish alone will produce leprosy. But I will say I believe that a fish diet is often a very important factor in the causation of leprosy, by preparing the soil for the seed.

We know that there are many people in the United States who cannot eat fish or strawberries on account of the unpleasant skin eruption which they produce. We know that when the skin is diseased and broken, the Lepra bacillus will find it much easier to enter the human economy than if it were healthy and unbroken. It would be just as correct to say that a fish diet alone would cause it. Men who have itch are more likely to have leprosy than are healthy men, simply because the skin is broken.

In this connection it might be well to mention the fact that, while a fish diet will have little effect on leprosy, a mixed diet of fish and milk will cause the disease to increase and the ulcers to enlarge rapidly.

VACCINATION AND ITS RELATION TO LEPROSY.

I believe that leprosy is contagious as syphilis is contagious, that is, by inoculation in some way or other. The Lepra bacilli must be transferred from the infected to the healthy person. This, I believe, can be done in several ways.

I will speak first of a few cases in which the disease has been produced by inoculation.

1. A European Sister of Mercy, who was sent to Guiana, was infected by being pricked with the needle with which she was sewing lepers' clothes.

2. A European child free from taint, while playing with a native child who was a leper, saw him stick the blade of a pen-knife into the anæsthetic part of the leg without experiencing pain. The European child took the knife from the native and tried to experiment on himself, but of course suffered from it. He afterward became infected and died with leprosy.

3. Kenu, a condemned murderer in the Sandwich Islands, was given his choice by the Queen, of being inoculated with leper lymph or being hung on a certain day. He consented to be inoculated and this was done by Dr. Arning. Within two years he was a confirmed leper. He died with leprosy in about six years.

I believe it is an accepted fact that leprosy can be inoculated and that in this

way it has increased and will continue to increase at a fearful rate until *arm-to-arm* vaccination is abolished.

General arm-to-arm vaccination has been practiced in the Sandwich Islands for years. Within the last few years leprosy has made a fearful advance there, from the time when no one had leprosy (1858) to the present day, when we find one-thirtieth, and some say one-tenth of the population infected with it.

Two years after a general vaccination took place there in a district which had been remarkably free from leprosy, from fifty to sixty cases were found. Cook estimated that the population of these islands one hundred years ago, was about 400,000, to-day there are less than 18,000, fifteen hundred (1,500) of whom are now in one leper asylum.

The vaccinators in India are ignorant men and unable to diagnose a case of leprosy or skin disease of any kind if they should see it. They never examine the people, and vaccinate all they can corner or catch up. Lepers are often included in the first, and lymph is taken from their arms and healthy people vaccinated with it, as the following case will show:

A leper named Munorita, thirty-four years of age, residence Koth, near Ranikhet, has had leprosy twelve years. Was vaccinated *since* he had leprosy. He was examined when he was vaccinated. Others were vaccinated with the same knife before it was cleaned. Later on lymph was taken from his arm and others were vaccinated with it.

It is useless to take up more time with this sad story. I claim that leprosy is being spread by the lancet and can confirm what I say. Gentlemen, it is time for the physicians of these countries to call a halt before this curse reaches around the world and knocks at our own doors. If the profession will not take up the fight for right, who that can remains to do so?

The natives of India object to having their children vaccinated for two reasons: First, because they have seen so many of them die after the operation, while others were wrecked for life and would have been far better off in their graves. About 3,000,000 people were vaccinated in India last year, and God alone knows how many of those poor creatures will have leprosy or some other trouble later on.

There is another reason why they object to it, and that is because they say a child is to be born who will be their king, and who will free them from the hands of the English. The blood of this child will be as white as snow. The English in some way discovered their secret, they say, and commenced dipping into the arms of all the children to find the white-blooded child. If it is found, it will be put to death.

I believe vaccination is a blessing when carried on right, but it is surely a curse as now practiced in India and some other countries.

DURATION.

The average life of a man suffering with tubercular leprosy is about 9½ years, while with anesthetic leprosy they live about 18½ years after contracting the disease.

TREATMENT.

It would be impossible for me at this time, to speak of all the drugs that have been used in the treatment of leprosy. Chaulmoogra and Gurjun oils have been used by most every one who has anything to do with leprosy, but so far these oils have failed to cure. Arsenic is considered by some to be good. Danielssen used iodide of potassium for over 40 years in the treatment of leprosy, with a marked degree of success.

There are no two cases which we treat alike. Ten per cent. solution of pyrogallic acid painted over the anesthetic spot often does good and the anesthesia disappears. I pay very little attention to the ulcers other than to keep them clean, as I believe to heal them by a local application alone will do more harm than good. As in other diseases of this character, an alterative is indicated. As an alterative I generally use the elixir iodo-bromide of calcium compound (Tilden's), as the calcium salt is much better tolerated by the stomach and is prompter in its action.

If the ulcers are slow about healing, I generally pack them with equal parts of acetanilid and sulphate of quinine. Ichthyol has been used by some, but after trying the various remedies I think the treatment outlined will give better satisfaction than any other. We can heal ulcers, stop the most distressing symptom of the disease, mutilation, and place the patient in a fairly good condition.

AUSCULTATORY PERCUSSION AND ALLIED METHODS OF PHYSICAL DIAGNOSIS.*

Concluded from page 586.

A. L. BENEDICT, A.M., M.D., BUFFALO, N. Y.

EXPLANATION OF THE CHARTS.

The writer regrets that he could not have had the assistance of someone accustomed to draughting, but it seemed better to sacrifice the æsthetic appearance rather than to allow technical inaccuracies

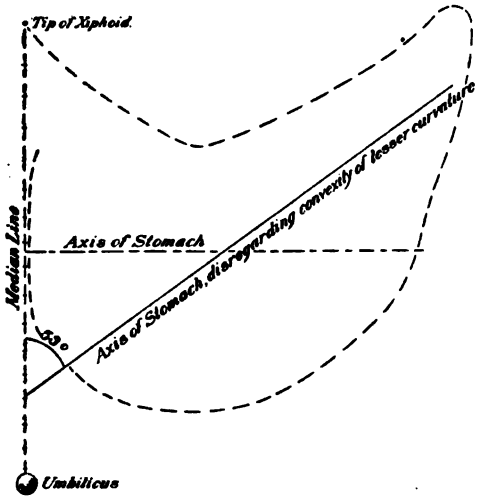

FIG. I.

to detract from the value of diagrams prepared by one unfamiliar with medical science. The charts were prepared by placing the original tracings on card-board, following the lines with a style and marking the depressions with ink, and then reduced to scale.

I. The patient was a large, flabby, middle-aged woman with chronic diffuse nephritis. She was subject to so much gastro-intestinal fermentation that her abdomen always suggested ascites, which was never found. The chart was made one hour P.C., when the stomach was distended nearly to its maximum capacity. The axis appears to be almost in the horizontal line but, for the purpose of comparison, we must allow for the distension of the lesser curvature. The gastric area, though absolutely one of the largest in the series, does not indicate the degree of dilatation and ptosis seen in Nos. 3, 5, 7 and 9, since it does not pass to the right of the median line nor within an inch and a-half of the level of the umbilicus.

II. This chart represents the contours of the stomach on two occasions, eleven days apart. The dotted lines indicate the result of the first examination, three hours P.C. For some reason, the upper part of

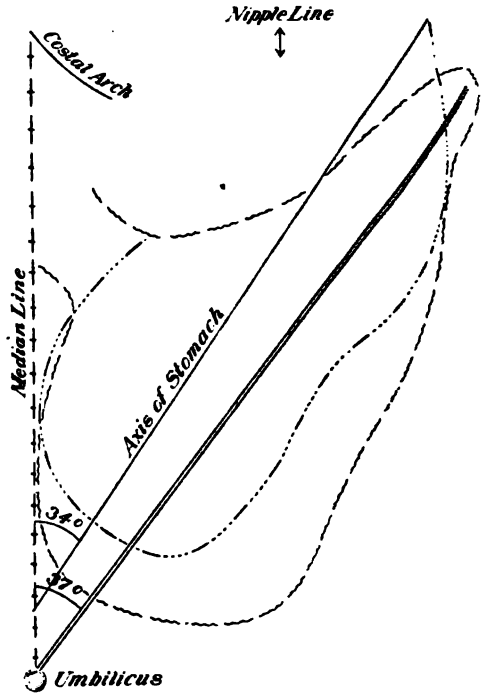

FIG. II.

the organ was not found. The second examination (marked in wavey lines) was made two hours P.C., when the stomach was

*Being the Merritt H. Cash Prize Essay of the Medical Society of the State of New York, 1895.

more distended. The patient was a remarkably long-chested individual, although only 5 feet 10½ inches tall. It will be seen that the distance from xiphoid to umbilicus was nearly two inches greater than in the first patient. The gastric

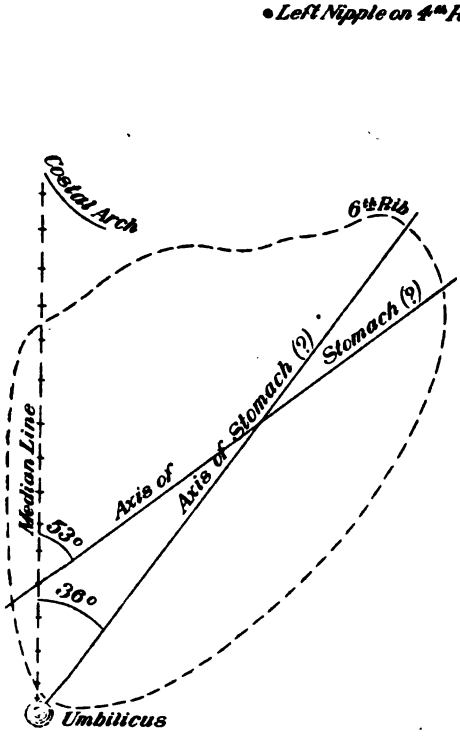

FIG. III.

axis, also, was nearly 20° farther from the horizontal. In each diagram, especially the first, is seen a tendency to the formation of two gastric compartments. Some have asserted that by auscultatory percussion the beginning of the duodenum can be located. The writer has frequently found a narrow projection from the right border of the gastric area, which, apparently, marked the duodenum. In this case, there seems to be a downward dilatation of the lower compartment of the stomach, since the duodenal projection, if such it be, usually appears not much above the lowest part of the greater curvature.

III. The patient had suffered for four or five days during a voyage, with gastro-enteritis. The symptoms had largely subsided without medical aid, though there was still tenderness over the abdomen, belching of gas and general gastro-intestinal distension. The stomach, though not sufficiently distended to inflate the lesser curvature, passed to the right of the median line and descended to the umbilicus, suggesting a very moderate and probably temporary dilatation. It is questionable which of the two axes drawn in the diagram represents more fairly the general direction of the stomach. The patient, though five feet eleven inches tall, was not "long-chested," and we should expect simply the average inclination of the stomach.

IV. This represents the stomach of a short and naturally broad-chested woman, though at present emaciated on account of fibroid phthisis. She is subject to occasional attacks of fermentation due to subacid dyspepsia. Although the stomach reaches farther to the right than is generally demonstrable, its area is not abnormal. The diagram is introduced, partly to illustrate the inclination of the axis, but more particularly to show the difference between the area as mapped out by auscultatory percussion and by auscultation of the tuning-fork vibrations. The dotted lines represent the area as determined by the latter method which seems

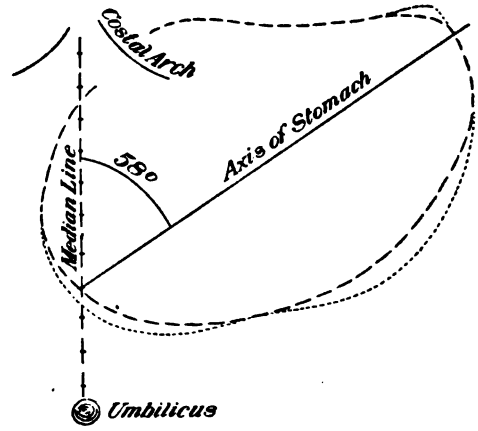

FIG. IV.

to be slightly more delicate. Where the dotted lines are absent, the two areas coincided.

V. This was a case of subacute gastritis, which, from its occurrence during an epi-

demic of typhoid fever and, on account of diarrhœa and a rise of temperature to 102.2°, occasioned considerable anxiety. The patient was a young man of average

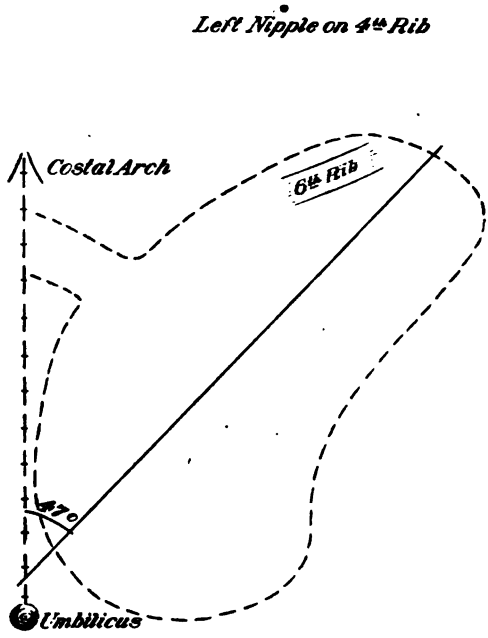

FIG. V.

height, rather stockily built. The inclination of the axis of the stomach is a little greater than in a person of average build. Like that of Case II., this map in-

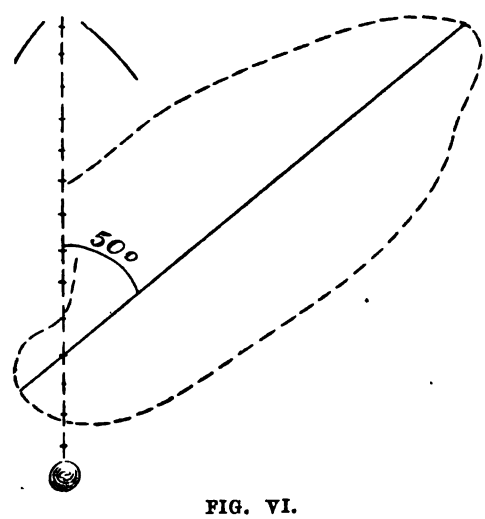

FIG. VI.

dicates a partial constriction of the stomach into two compartments, the duodenum being apparently high as if from a downward dilatation of the lower compartment. The chart was made in the morning, twelve hours after a meal.

VI. This map made two hours after eat-

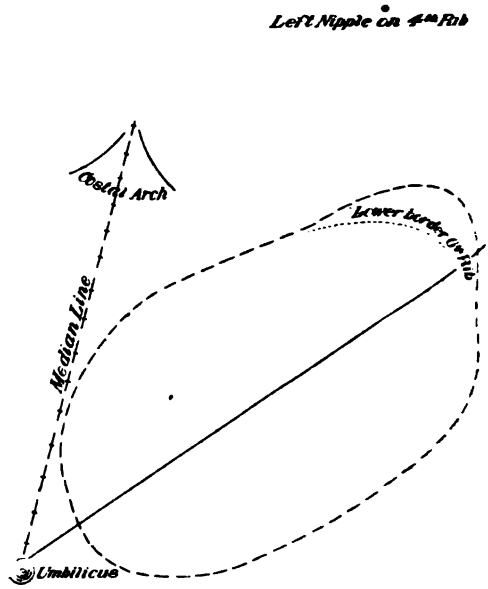

FIG. VII.

ing, represents the stomach of a nurse, aged forty, who suffered greatly from subacid and fermentative dyspepsia, appar-

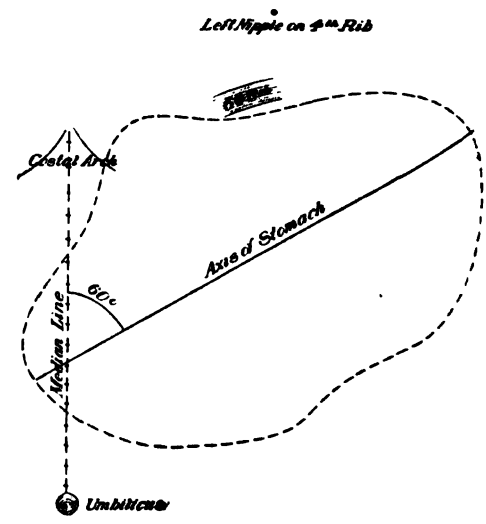

FIG. VIII.

ently induced by fatigue. She was of large frame and broad-chested. The beginning of the duodenum appears in the usual location. The tuning-fork was used in making this map.

VII. This represents the stomach of a young man in the first week of typhoid fever. Although no food had been taken for sixteen hours (this was at the first visit) the organ was greatly distended with gas. It will be seen, however, that there was no essential dilatation. During the course of the examination, a gurgling was heard at the pylorus and it was found that the superior convexity of the stomach had descended as indicated by the dotted line.

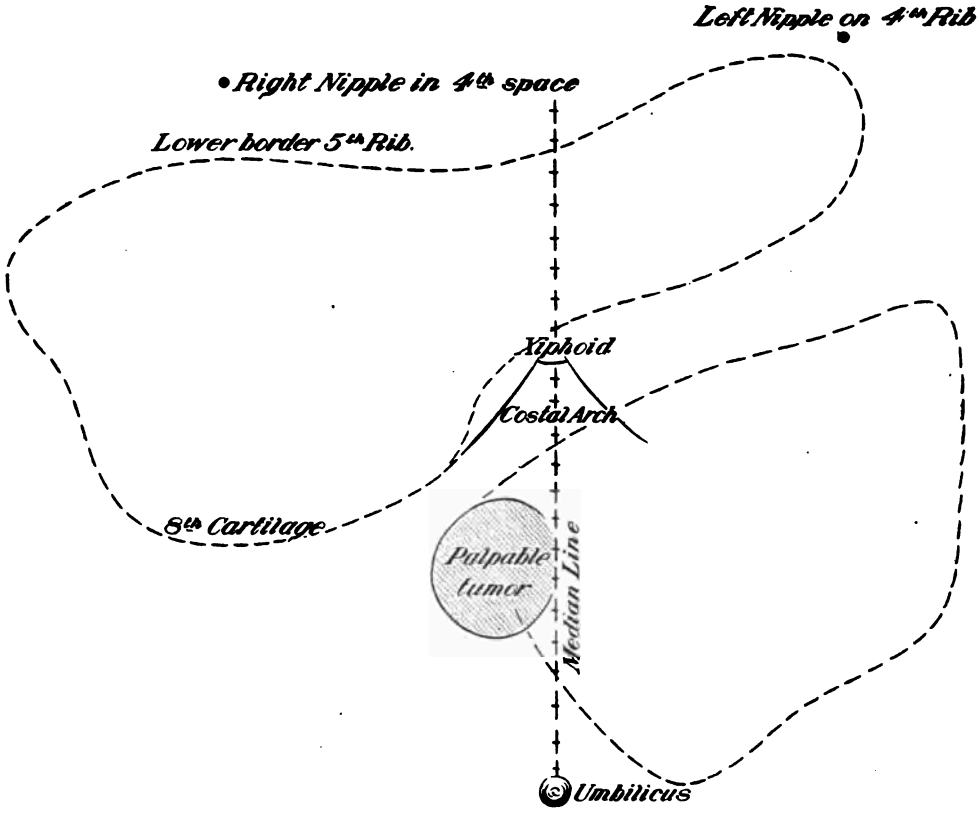

FIG. IX.

VIII. This was a case of dilatation seen in consultation. The map was made three hours and a half P. C. and, although corroborative of dilatation, it would not suffice to establish the diagnosis without confirmatory evidence.

IX. The case was one of pyloric cancer complicated with hepatic cirrhosis. The patient had been some hours without food, so that the stomach was relatively contracted, yet it was evident that secondary dilatation had occurred. The condition is plain from the diagram. It will be noticed that the nipples are not on a level, although care was taken to have the arms symmetrically disposed, so as to prevent stretching of the skin.

X. This was an extremely interesting case of hepatic carcinoma. Not having seen the patient during life, an excellent opportunity was afforded for testing the reliability of auscultatory percussion. Long pins were driven through the tissues at the limits of the area of resonance. (It will be noted that the word resonance has not the same sense as when used of ordinary percussion.) A piece of paper was then applied to the body, being punctured by the heads of the pins. The outer limit of the left lobe, falling over the 6th rib, could not be marked by a pin but it was verified by the section. The right lobe was correctly outlined, the left extended a little higher than the pin-marks. Depending from the liver was a cancerous mass which had been overlooked. On account of rigor mortis and gaseous distension of the stomach and bowels, it was neither palpable nor percussible. So far

from indicating a failure of auscultatory percussion, this test simply illustrates its physical limitations, since it shows that vibrations imparted to an organ are practically limited to tissues of the same kind. In other words, the cancerous mass, though growing from the liver, was a separate "pathological unit."

At another autopsy, the attempt to locate the liver was a failure. The subject had been dead four days and decomposition had engendered an enormous amount of gas. Being unable to trace the liver beyond the median line by auscultatory percussion, the stethoscope was moved to the left. What was supposed to be the upper margin of the left lobe was then marked, but on account of the inflation of the stomach, the lower margin could not be found. The section showed that the right lobe had been fairly well located, the left lobe was almost wanting, the liver being extremely contracted. The line marked as the upper margin of the liver corresponded to the lower margin of the lungs. In moving the stethoscope one of the rules of auscultatory percussion had been infringed, for it had been transferred from the area in which the liver was superficial to the area of the inflated stomach, which had exceeded its normal bounds. The failure, therefore, in spite of the unfavorable circumstances, was attributable not to the method but to a blunder in carrying it into execution. It is difficult to learn the lesson that in physical examinations we must trust blindly to our senses, not to previously formed conceptions nor to the probabilities of the case. Afterward, any discrepancies are to be carefully weighed and the decision made accordingly. The writer, in the present instance, was really making an accurate map of the liver when he thought himself failing, and by following the notion that the left lobe was present to a demonstrable extent, the error was made of mapping out part of the stomach under the delusion that it was part of the liver.

A Large Gall-Stone.

Dr. T. A. McGraw reports in the Medical Age a case of intestinal obstruction which was found on operation to be caused by a gall-stone completely filling the lumen of the intestine, at the junction of the jejunum and ileum. The calculus weighed 250 grains.

EMPYEMA OF THE MASTOID AND ITS RELATION TO ACUTE AURAL DISEASE.*

S. M'CUEN SMITH,† M.D., PHILADELPHIA, PA.

The importance of the subject is manifestly so great and its field so extensive, that anything like an exhaustive consideration of this interesting disease would not be possible within the limits and sphere of this brief paper. I will, therefore, confine my remarks to those cases of mastoid empyema that result as a complication of, or an extension from an acute suppurative inflammation of the middle ear.

Former teachings as to the etiology of this disease would lead us to believe that mastoid abscess, when the result of aural disease, arises only from a chronic suppurative inflammation of the middle ear, and that it rarely if ever occurs as a complication of an acute discharging ear. When we consider the destructive action to the superficial tissues and the underlying bone caused by the long-continued presence of fetid and bacteria-laden pus, we are justified in the plausible theory that empyema of the mastoid should occur only in the chronic form of suppurative otitis media, as considerable time usually elapses before carious involvement can reasonably be expected to have taken place. This explanation probably accounts for the prevalent belief that the otorrhœa must have existed for a longer or shorter period before the danger of mastoid complication arises.

It is not necessary, however, that the integrity of the mucosa lining the tympanum and the mastoid antrum should be seriously impaired, in order that the inflammatory products may find their way from the former cavity into the latter. Empyema of the mastoid as a result of an acute aural disease, may be caused by direct continuity of structure; or the infectious matter may be conveyed by the venous circulation to the mastoid or other parts of the cranial cavity. Likewise the canaliculi, through which pass the nutrient vessels from the carotid canal to the mucous membrane of the tympanic cavity, may become the carriers of the microbes of otorrhœa, and thus cause sinus thrombosis, arteritis, lymphangitis or phlebitis of the venous plexuses.

In a paper read before this society one year ago, I took occasion to call the attention of its members to the importance of the *early recognition* and *prompt treatment* of all *acute* inflammatory conditions of the ear, and I can offer no better suggestion at this time than to repeat this appeal, and at the same time remind you of the grave responsibility that rests with every practitioner of medicine who would neglect such an important duty. This obligation of the physician becomes especially imperative from the fact that if the initial lesion receives prompt and proper care, these serious complications now so prevalent will be reduced to a minimum. I might even predict that they would eventually be confined to some most unusual cause, or occur as the result of trauma.

Within the past few months I have seen eleven cases of mastoid empyema, all resulting from an acute otitis media. The time that elapsed between the beginning of the middle ear disease and the establishment of the mastoid implication, varied from three to seven weeks. The ages of the patients ranged from nine months to forty-four years; not any of this number ever suffered from a previous ear disease. In four of these patients, the abscess was superficial; of the remaining seven, five were confined to the mastoid antrum, while two involved the mastoid cells as well. In four of this number, the pus burrowed its way from the antrum out through the thick plate of bone and was deposited beneath the periosteum, so that a Wilde's incision was all that was necessary to establish a free communication between the external auditory canal and the spontaneous opening into the antrum. In not one of these four cases, had the aural disease been present for a longer period than six weeks, and in each case (all being adults) we were assured that at

* Read before the Pennsylvania State Medical Society at Chambersburg, Pa., May, 1895.

† Clinical Professor of Otology in Jefferson Medical College; Surgeon in charge of Ear, Throat and Nose Department of Germantown Hospital, Philadelphia.

no previous time had they suffered from any aural disease.

It is indeed remarkable to note the destruction that took place here, not only to the soft parts, but to the dense osseous structure as well, in the brief space of six weeks or less; furthermore, it is even more interesting, and at the same time much more difficult to explain why the confined pus burrowed its way out through the thick external plate of bone, instead of selecting the thin osseous walls that separate the mastoid and the middle ear cavities from the interior of the skull, where considerably less resistance would have been encountered.

The following interesting case will serve to illustrate the foregoing observations:

M. K., a resident of Philadelphia, began to suffer from an ear-ache on February 7th last, which he thinks came from "catching cold." He was treated for "neuralgia in the right ear" until February 22nd (a period of fifteen days), when the ear began to discharge. He was then informed that he was suffering from an abscess. The discharge continued until the 5th of March, at which time it ceased, and he was pronounced well, although the pain in his head was constantly growing worse. On March 12th the severe pain was again somewhat relieved by a free escape of pus from the tympanum. About this time a swelling appeared behind the ear, which was treated by blood-letting, blisters, etc., until the 21st of March, when the swelling over the mastoid decreased somewhat in size, and the pain grew materially less. He came under the writer's notice on the 2nd day of April, when an immediate operation was advised. Under general anesthesia the Wilde's incision was made. This not only evacuated a large quantity of pus, but revealed an opening into the mastoid antrum about the size of a ten cent piece which communicated freely with the tympanic cavity and external auditory canal.

The after treatment consisted in thorough irrigation with a hot antiseptic solution, and keeping the wound packed with iodoform gauze (renewing the same every day) until all evidence of pus had disappeared and the wound healed from the bottom. The patient made an uninterrupted recovery. Within four weeks after the operation the wound had entirely healed, and his hearing power had become quite normal.

Several points are worthy of note in the above patient, which are applicable to nearly all similar cases: 1st. In all probability, the disease would never have progressed further than an acute tympanic abscess if the presence of pus within the middle ear had been primarily recognized and immediate steps taken for its proper evacuation. 2nd. When the pus made its appearance by bursting through the membrana tympani, and the pain over the head continued to be severe, the serious character of the disease present should have been immediately recognized. 3rd. This, and many other cases that we could quote, demonstrates conclusively, that serious mastoid complications can, and often do develop from an *acute* inflammation of the middle ear. 4th. That the early recognition and prompt treatment of all acute diseases of the ear will usually result not only in their speedy cure, but such serious complications as above narrated will be most uncommon.

A New Treatment of Whooping-Cough.

Lyon Medical publishes an abstract of an article from *Medecine Moderne*, in which M. de Chateaubourg describes a new treatment of whooping-cough, which consists in injecting, subcutaneously, two cubic centimetres and a half of a ten per cent. solution of guaiacol and eucalyptol in sterilized oil. After the third injection the fits of coughing diminish noticeably, the appetite returns, and, as the vomiting rapidly ceases and the general condition begins to feel the good effects of the treatment, the whooping-cough disappears at the same time. The author reported five cases.

A CASE OF PNEUMONIA TERMINATING IN ABSCESS OF THE LUNG.

CLARA T. DERCUM, M.D., PHILADELPHIA, PA.

E. S., American, of German parentage, aged eighteen, a large, well-developed, robust lad, went to bed on the evening of February 2, 1892, apparently in perfect health. At four o'clock the following morning he was seized with a chill so severe in character as to shake the bed. Simultaneously with the occurrence of the chill, an agonizing pain was felt on the right side posteriorly, somewhat below the angle of the scapula. After the subsidence of the chill he succeeded in arousing his mother, who was sleeping in an adjoining room, and implored her to give him some relief. All her efforts in this direction proved fruitless and as soon as the day broke I was sent for.

When seen his condition was as follows: Respirations forty-eight per minute and extremely shallow; pulse 180 per minute, tense and full; temperature 105° F. On auscultation the crepitant *râle* and broncho-vesicular breathing were heard at the base of the lower lobe of the right lung. Frank pneumonia was diagnosed. The chest was enveloped in a cotton jacket and two and a half minims of the tincture of aconite in spirits of menderismus and neutral mixture, was given every two hours. The worst feature of the case, however, was the intense pain very soon complained of in the lower part of the chest and the upper part of the abdomen on the right side, which made it probable that the pleura covering the base of the lung immediately over the diaphragm was involved. The respiration, in consequence, were very shallow from the fixation of that muscle. Hot applications, dry or moist, had no effect whatever on the pain, and he moaned incessantly for several days. The pneumonia seemed to be limited to the base and the posterior part of the right lower lobe, the breathing anteriorly being clear and vesicular.

February 4th his pulse was 160, respiration 50 and temperature 105°F. February 5th the pulse was 120, soft and weak. Rusty-colored sputum now made its appearance and was expectorated very freely for about a week.

The following treatment was instituted: Whiskey, half-ounce every two hours; ten drops of the tincture of digitalis, one-thirtieth of a grain of strychnine and five grains of carbonate of ammonia were given every four hours; one grain of the aqueous extract of opium was occasionally given by suppository on account of the intense pain present; milk and broths were given *ad libitum*.

His temperature varied from 104° to 105°F; his pulse from 115 to 120, and his respirations from 40 to 50 per minute until February 12th, when his temperature suddenly fell to 99°. Instead of remaining at this point, it again rose in the evening to 100°, and kept rising daily morning and night, so that by February 28th it had reached 102° in the morning and 104° in the evening. His respirations now varied from 30 to 40, and his pulse from 110 to 120 per minute.

During the second week of the disease, the pain being still very severe, small doses of salol and phenacetine were tried without effect. This pain continued well into the third week, when it gradually began to disappear. On the fourteenth of February, pain began in the left arm, and pressure over the median nerve elicited marked pain. Iodine was painted along the course of the nerve. A little later the same pain commenced in the right arm, and soon pain showed itself in both legs and feet, the soles of the feet being so sensitive that even the slightest touch seemed to cause excruciating pain. However, the pains began gradually to ameliorate, and entirely disappeared by February 28th.

As before mentioned, cough commenced on February 5th, when rusty sputum was expectorated. This continued for one week when it ceased. On February 29th at about 10 A. M., slight coughing commenced and continued throughout the day. It was dry in char-

acter. About 5 P. M. of the same day, blood, mucus and pus suddenly began to well up in mouthfulls, and about 7 P. M. fully one pint of this material had been expectorated. His temperature now registered 102.5°F.; respirations were 34 and pulse 120 per minute. This paroxysmal coughing was followed by extreme exhaustion. These attacks occurred almost daily, and considerable quantities of pus and debris were expectorated in variable amounts. Expectoration continued until April 5th, when it ceased. However, it recommenced slightly on April 25th and continued until the middle of May.

The temperature from February 29th, until March 4th, varied from 100° to 102.5° F. It then increased daily, so that on March 14th, the evening temperature was again 104°. It now gradually declined until March 20th, when it registered 99° and remained so for several days. It then gradually rose again, so that on March 27th, the evening temperature was 102.5°. It henceforth slowly declined to the normal, which was reached on April 5th, and so continued during the remainder of the illness.

The lung had been examined from time to time and the following physical signs were noted: February 15th, there was bronchial breathing to the angle of the scapula, with flatness on percussion by February 20th, this conditions had advanced over the whole posterior portion of the lung, and extended a little beyond the axillary line anteriorly; here the breathing became vesicular in character and was so over the whole anterior part of the lung. There was entire absence of vocal fremitus at the base of the lung posteriorly. On the twenty-seventh of February a vesicular element was discovered at the lowest portion of the lung. This gradually extended upwards daily, and by March 15th, could be heard above the angle of the scapula. April 1st, distant vesicular breathing could be heard all over the posterior part of the lung. Vocal fremitus had now returned.

April 3rd, a small abscess that had found on the sacrum over a bed sore was opened and found to lead by a fistulous tract to a large abscess in the right buttock, which discharged over a pint of pus. Although this abscess was packed and treated antiseptically it discharged for fully six weeks.

The retentive powers of the boy's stomach were marked; he never vomited either food or medicine throughout the whole course of his illness, and his appetite was simply voracious. After the first two weeks of his illness he was given meat, eggs, broths, oysters, vegetables and easily assimilated food of all kinds.

During the latter part of the disease, quinine, potassium, iodine and strychnine were the drugs used. Whiskey was freely used in variable quantities throughout his illness. After the expectoration of pus commenced, inhalations of creosote and oil of eucalyptus were used several times daily in a steam atomizer, which was also kept going in the room constantly so that the atmosphere became impregnated with the drugs. This was done at the suggestion of Dr. H. C. Wood, who saw the lad in consultation after the rupture of the abscess.

In looking over the literature of the subject I find that several cases of abscess of the lung following pneumonia have been reported. In one case, although the abscess had ruptured into a bronchial tube, an incision was made and the abscess drained externally. This was followed by an empyema, which had to be drained also, nevertheless the patient, a lad of fourteen years, made a good recovery (Hawkins, *Trans. Clin. Soc.* London, xxiv, 1891).

Another case of double pneumonia in a man fifty years of age, with chronic Bright's disease was followed by an abscess which ruptured into a bronchial tube. Recovery followed, after an illness of several months, without external drainage (Lewis, *St. Louis Med. Review*, 1889).

Another case, which is of interest because the abscess ruptured externally, occurred in a little girl, eight years of age. The abscess pointed one and one-half inches below the right nipple, and ruptured spontaneously nearly two and a-half months after the beginning of the pneumonia. Antiseptic dressings were used over the opening which admitted air freely, nevertheless, this case was also followed by recovery (Edson, *Med. Record*, xxxiv., 1888).

My patient is now in the enjoyment of the most robust health. For a long time there was a marked flattening of the right side of the chest, but at present there is no difference between the two sides.

HYDROCEPHALUS; ASPIRATION OF LATERAL VENTRICLE; EXCISION OF THE THYROID.*

ROSWELL PARK,† A.M., M.D., BUFFALO, N. Y.

Our patient is a little child of three. It is the first born of its parents. During labor, which occupied forty-eight hours, forceps were used and when the child was finally born, there was a "gathering" on the right frontal region at the junction of the forehead and scalp. This discharged for about three weeks. The child was breast-fed and was weaned at the expiration of a year. When two years old he had a convulsion and he had two or three every day for a month. He would lie quietly and shake his right hand. The duration of the attacks was from two to five minutes. The intervals gradually became longer but the convulsions became more severe. The convulsions were not connected with teething. The bowels and bladder are normal in function, the child can utter only two or three words, though he understands perfectly what is said to him"—probably a mother's exaggeration. A second child has been born that is perfectly healthy.

A few weeks ago, I operated upon this child for a combination of hernia and hydrocele and at that time, I called your attention to the irregularity of the skull. With the head shaved preparatory to operation, the irregularity is still more marked. We have made a plaster cast of the head for reference after the operation. The child is not a driveling idiot but is an imbecile. It takes an interest in what is going on and plays a little, but it has every now and then a convulsive twitching and rigidity of the hand and arm. Without any urging on my part, the parents have asked to have something done for the relief of its present deplorable condition, and have expressed themselves as willing to abide by the result, whatever may be.

I shall try to find out whether this irregularity of the skull is due to thickening, which I do not believe, or whether there is a cyst, either extra or intra-dural, or whether there is a dilatation of the ventricle on one side or both. This last I regard as the most probable condition. The case is evidently not one of micro-cephalus and the opposite condition or enlargement of the skull is most often due to hydrocephalus, which usually means a dilatation of the lateral ventricle. Unilateral hydrocephalus is rare. When we consider that instruments were used at the delivery and that the child was injured about the head, it is possible that there may have been a hemorrhage somewhere inside of the skull and that the blood-clot, instead of being absorbed, has undergone cystic degeneration.

The head has been shaved and scrubbed and enveloped in an antiseptic dressing which has been kept on forty-eight hours. Prior to operation, the head is again scrubbed with green soap and mustard, and then with a mixture of alcohol and ether to remove fatty debris from the skin. The Esmarch bandage is applied around the forehead to prevent loss of blood during the operation.

My first attempt, after penetrating the skull, will be to ascertain the condition of the lateral ventricle on the protruding side of the head, that is, the left. It has been shown that the lateral ventricle may be safely reached, and the anatomical directions for finding it in adults have been plainly given by Keen of Philadelphia. An opening is made, one to one-quarter inches behind and one to one-quarter inches above the external auditory meatus. Then, introducing an aspirator needle, or a grooved-director, it is directed to a point two inches above the opposite auditory meatus. This will tap a distended ventricle and will do no damage to the intervening structures. The normal ventricle in the adult is reached at a distance of about two to one-quarter inches; if it be dilated, it will be tapped at a less distance. In the case of this child, although the skull is relatively large, I have modified the distances. The trephine is located three-quarters of an inch behind and above the auditory meatus.

---

*Clinical Lectures at Buffalo General Hospital.
†Professor of Surgery, University of Buffalo.

I will make the skin flap large enough to suffice for further interference, if necessary. The periosteum is separated from the left parietal bone by a crucial incision. As there is usually no diploë in a child of this age, we shall penetrate the skull very speedily, and extreme care is necessary to avoid damaging the parts beneath. On exposing the dura, there is no extreme brain tension. I mark the point toward which the needle is to be directed with my finger. There is a large vein running across the dura, almost in the middle of the trephine opening. This, of course, must be avoided. On introducing the needle to a depth of one-half an inch perfectly clear serum exudes. This shows that the conjecture of distended ventricle was correct. But the mere withdrawal of this fluid will not effect a cure, we must provide drainage. I make a larger opening in the dura and now the fluid drips out. I shall make use of an instrument originally devised to dilate sinuses, to push a rubber drainage tube through the brain tissue. Even the slight dilatation of the needle track caused by the slender blades of this instrument allows the fluid to flow freely. At first, it was blood-stained but now it is clear. The impetus of the heart-beat is seen in its rythmic flow. If the fluid were allowed to drain away too fast, the sudden change in intra-cranial tension would produce shock. I will, accordingly, catch the tube with hemostatic forceps. It is stated in the American Text-Book of Surgery that there is no case on record of permanent recovery from this operation, but from other reading, I think I am in a position to contradict this statement, although recovery may not have occurred after cases treated as deliberately as this one. In all, about a hundred cubic centimeters of fluid have drained away from this ventricle. The other wound is closed with catgut, leaving space for the drainage-tube. The usual antiseptic dressing is applied.

This child died a few weeks latter of sheer inanition, without the slightest sign of sepsis, nor reason for attributing death to the operation.

EXCISION OF THE THYROID.

Ten days ago you saw me operate on a little girl, aged twelve, who had a large thyroidal tumor which pressed on the trachea, displacing it to the left and compressing it into a scabbard shape, the anterior edge presenting. The normal relation of the parts was so much altered that the operation was an extremely difficult one. At one time it seemed doubtful whether the child would rally, and artificial respiration had to be resorted to. Had it not been for the precaution of first performing tracheotomy and leaving long sutures hanging from the trachea, so that it could be pulled into place whenever necessary, I believe the child's life would have been lost. The trachea was covered to such a depth by the tumor, that it was not possible to remove the tumor and then expose the trachea at our leisure, but it was necessary to tear the tumor apart in order to expose the trachea without delay. The condition of the patient was such that, after having provided for easy respiration, it was decided to postpone the extirpation of the tumor. The silk threads which were left in place have rendered good service, for once or twice the tube has slipped out of place and breathing has been interfered with. During the last two or three days, the presence of the tube has caused some irritation of the margins of the wound.

Yesterday, I extirpated the tumor which was the original cause of the trouble. You will see that it is a large mass for a small child's neck. It is not the ordinary form of goitre, which is either a fibrous hyperplasia or a fibro-cystic degeneration of the thyroid body. This tumor is a hypertrophy of the whole thyroid body and is not very different from the normal structure of the organ, although it looks in some respects more like the thymus. The lobular structure of the thyroid extended in every direction. The upper limits were above the hyoid on either side; downward it extended behind the sternum at least an inch below the junction of the sternum and clavicle. It wrapped itself around the trachea and separated the trachea from the œsophagus. To-day, the child is in good condition and I have every reason for expecting her to recover.

The question now arises, what will be the effect of removing the whole thyroid body? This brings up the subject of the physiological function of the thyroid and, in this connection, notice that I call it a body and not a gland. Having no duct,

it is not entitled to the designation "gland" as are the ordinary secretory and excretory organs of the system, and I prefer to call the thyroid, thymus, suprarenals and prostate "bodies," since that word implies nothing as to their function and commits me to no theory as to their action in the economy. The peculiar tissue of the thyroid has properties some of which are known and some of which are unknown. In spite of the great amount of research as to the functions of the thyroid body, we can only say at present that its cells either remove from the blood—and perhaps from the lymph—some effete matter, or else that they elaborate some material that is necessary for the proper working of the body. Whether the purpose of the thyroid be formative or eliminative, I do not think we positively know. It is possible that both functions coëxist. We do know that, obscure as is its function, the thyroid is essential to perfect health and that various unpleasant sequences result from its total removal. We can experimentally remove the thyroid from a kitten, or sometimes a mature cat will survive the operation, and after three or four days the animal will show signs of intoxication, and will die in the course of a few days more, with symptoms of that disease which neurologists have called "tetany" and which is marked by spasmodic contractions of the muscles, by loss of true consciousness and by cerebral excitement. Similar cases are known in children and have occurred in adults. The consequences of total removal of the throid do not seem to be always the same in the human being. Sometimes a cretanoid condition results—as after experimentation on animals—do not understand me to refer to the specific infectious disease. Sometimes myxœdema results; sometimes the changes are not so much physical as mental, and a failure of intellect may develop which imitates cretinism, which is a congenital idiocy associated with goitre.

No one can foresee in any particular case just what will be the consequence of total extirpation of the thyroid body. The practical deduction, however, is that it is wise to leave a little thyroid tissue in place, unless there be malignant disease which demands its total extirpation at all hazards, and may call for the removal of much of the surrounding tissue as well as that of the thyroid. In the present case, the enlargement was of a benign nature, though you can seen how nearly fatal even a benign tumor may become from its interference with vital processes.

In operating on such cases, we have to decide between removing too much tissue, and of performing an incomplete operation which may call for a second interference by the surgeon at a later time. Accordingly, experiments have been tried on animals to determine approximately how much of the thyroid tissue may be removed without danger of serious after effects. From a large number of observations, the conclusion has been reached that we may prevent tetany and the other manifestations of poisoning by leaving in place about one-seventh of the entire organ.

This specimen shows little prolongations of the structure of the organ and I have every reason to believe that there have been left behind little islands of thyroid tissue sufficient to obviate serious trouble. However, if it be shown that an insufficient amount of the thyroid remains in place to perform its normal function, we have recently learned that we can atone for its loss by administering the thyroid of animals internally. We can employ the fresh thyroid or various extracts and dessicated preparations. Judging from this observation, it would seem that the thyroid is not an eliminating body, but that it supplies something necessary for the continuance of the vital processes. In a sense, therefore, the thyroid may be regarded as a secreting body or gland.

This patient made a prompt and and uninterrupted recovery.

A FATAL CASE OF TYPHOID FEVER.*

A. F. MYERS, M.D., BLOOMING GLEN, PA.

Miss G., aged 28, consulted me on March 2d, concerning a loss of appetite, slight headache, a little nausæ, chilliness, disturbed sleep, feeling of depression, muscular weakness and general indisposition. An examination revealed a pale, coated tongue, the tongue itself of a heavy, flabby appearance, and a tendency to constipation; no elevation of temperature. This condition of affairs continued for five days, when on March 7th the prodromic period ended and the first rise of temperature of half a degree was noted. The pulse rate slightly increased, the coating on the tongue being darker, with a disgust for food and an occasional nausea and show of epistaxis. More headache and the constipation. In fact my suspicions were confirmed and I pronounced my diagnosis of typhoid fever as we usually meet them. The temperature now run a typical course upward.

Thus passed on the first week of fever, all the symptoms becoming exaggerated with the exception of constipation which happily yielded to the exhibition of compound cathartic pills. Slight tenderness was now felt in the right illiac fossa and the appearance of sudamina in spots on the abdomen. The urine passed freely at regular intervals, no sediment and no albumen. Hence on March 17th,—mark the time—we had present a morning temperature of 101° and evening 103°, pulse rate 105 to 108 and some delirium during the night; more headache; only a moderate thirst and positive disgust for food.

There was *absent* on this day, and later, the characteristic symptoms of enlargement of abdomen, diarrhœa, tympanites, pain, sordies and irregular muscular action, this being about the beginning of the second week of fever.

During the following night the restlessness and delirium increased. Temperature at midnight was only 102.5°, and on the following morning, March 18th,—the fatal day—we found the temperature at 5 A.M. at 103°, accompanied by a violent throbbing headache. The patient stated that she felt worse in every way and mentally she was depressed. At 7 A.M. I was surprised to find the thermometer register at 104° and at 9 A.M. at 105°, the patient still conscious, and taking a little nourishment. At 10 A.M. the temperature was 106° and at 11 A.M., 108° in the axilla. The pulse rate from 130 to 140 per minute. The patient was now comatose and this high fever remained until death ended the scene at two o'clock that afternoon.

I was present when the patient died and having occasion to go to the room a half hour later I placed my thermometer again in the axilla and it still registered 108 degrees. What was the cause of my patient's sudden death, and why this elevation after death? Was it possible that the existing ailment was superseded by a more violent toxic influence—influenza—during the last day, or was the diagnosis in error?

Formulæ for the Use of Chloral Externally.

Dr. Brodnax (*La Semaine Medicale*) recommends the following formulæ for the external employment of chloral:

In cutaneous pruritus from urticaria, measles or other eruptions:

Chloral	ää o | 50 grs. xijss,
Carbolic acid	
Olive o l	50 | o ℥jss. gtts. xxx.

Apply locally.

In toothache:

Chloral	ää 5 | o ʒ j ¼.
Camphor	
Carbolic acid	
Glycerine	

Introduce a ball of cotton moistened with this mixture into the cavity.

In earache.

Chloral	ää o | 50 grs. xijss.
Camphor	
Carbolic acid	
Castor oil	15 | o ℥ iv.

Instill a few drops of this mixture previously warmed.

In acute coryza.

Chloral	o | 50 grs. xjss.
Castor oil	15 | o ℥ iv.

If applied to the nasal mucous membrane after cleansing of the surplus mucus this mixture will arrest the secretion, calm the irritation of the mucous membrane as well as the accompanying headache.

EDITORIAL.

HYPNOTIC SUGGESTION.

We have reached a period in medical progress when it seems proper to come to some conclusion in regard to the use of hypnotism, and while all will not arrive at the same conclusion, we believe that the profession will agree that, except under rare circumstances, the medical use of hypnotic suggestion is to be condemned.

Under the name of mesmerism, hypnotic influence was variously regarded as a manifestation of super-human power, as a simple fraud, or as the expression of a force mysterious merely because inexplicable. The more thoroughly hypnotism has been investigated, the more have its apparent mysteries been dissipated until, doubtless many will, agree with the extreme opinion that the hypnotised individual is merely one who is sleepy and impressionable.

The chicken with its bill held on a chalk line, the person with no previous thought of suicide drawn by an irresistable fascination to leap into the rapids at the brink of Niagara—and there have been not a few such—the child soothed to sleep by the touch of its mother's hand, the hysterical girl who becomes a willing tool in the hands of the neurologist after gazing at a complicated mechanism of revolving mirrors, the idler lulled into dreams by the murmur of the wind through the leaves, all present various phases of the same condition. We consider that, literally as well etymologically, the hypnotic state is a sleepy state and that it differs from ordinary sleep only in the unusual time of its occurrence and in certain artificial restrictions commonly placed about it.

The hypnotic state, like true sleep, may be produced by the repeated and monotonous stimulation of any of the higher senses; notably by sight and to a slightly less degree, by hearing and by touch. The temperature sense is also obviously to be considered in this connection; apparently that of smell, but probably not that

of taste. Certain persons can not be hypnotized even with their own assistance, while others can not oppose the mesmeric influence. But this fact is no more remarkable than that some suffer from insomnia while others fall asleep in spite of efforts to keep awake.

But what of the state of catalepsy; of the almost miraculous results of suggestion; of the manifestations of cerebration of which the patient has no subsequent recollection? Even these phenomena, mysterious as they seem, are duplicated in ordinary sleep. Have you never been awakened by the telephone, perhaps even by the ringing bell, to a sense of the necessity of immediate action, and yet felt that every muscle was in a tonic spasm and that motion was impossible? Is there any reason to suppose that the muscular rigidity which the hypnotist, by seizing on just the right stage of manifestation on the part of the patient, presents as so striking a phenomenon essentially different from the similar condition which attends almost every awakening from normal slumber, and which one shakes off by "stretching?" At the time of President Garfield's death, we were awakened (apparently) to hear the tolling of the bells; we answered questions rationally and seemed to comprehend perfectly the significance of the occasion; yet, in the morning, we were surprised and dismayed to learn that the President had succumbed during the night, nor have we ever been able to recall the interval of apparent consciousness. We mention this not as a remarkable occurrence, but on the contrary as one that can be duplicated in the experience of many persons who display no particular tendency toward somnambulism in the wildest sense of the term. However, are the imitations of self-consciousness by hypnotic subjects any more remarkable, or do they show any difference in kind? In sleep, too, one yields implicitly to the most ridiculous vagaries of his dreams, and, when merely sleepy, one is easily influenced by arguments and requests that would not appeal to him if the mind were active.

We believe that the medical use of hypnotism is on a par with the practice of stupefying a patient with morphine, of deceiving him with false hopes, or gaining his acquiescence through direct misrepresentation. The end will stupify almost any means in some emergencies which the physician has to meet, and we would, therefore not go to the extent of condemning hypnotism altogether. But the fact remains that the neurologists who make a routine use of hypnotism and suggestion, are beginning to be looked upon by many of their confreres and, to a growing degree, by the laity, as verging on quackery.

Suppose that a patient presents himself to some neurologist, with a hysterical monoplegia, retention of urine, aphonia, or any functional trouble. He or she is put in a proper state for suggestion by means of some instrument, more or less elaborate, for producing visual fatigue, and the suggestion is made that, after such and such a time, a certain degree of improvement will be manifest. The patient returns for treatment, and at each visit the hypnotic suggestion is made of greater and greater improvement until a wonderful cure is effected. In this procedure, which we believe to be not an unusual one, three deceits are practiced. The patient recovers more than ever convinced of the genuineness of his disease, and, therefore, all the more apt to relapse into the same or some other hysterical manifestation. He and his friends are agreeably flattered by the mysterious nature of the cure. And, lastly, the neurologist is credited with power over disease far in excess of that warranted by the real nature of the case. We have heard a prominent clergyman, formerly a physician, refer publicly to an hysterical aphonia from which he suffered, as a malady that threatened his

life. On the other hand, the physicians who treated him referred to the case in a medical meeting as an example of the wonderful benefit of hypnotism. In our opinion, such a "cure" is by no means a proper one.

If a physician is called upon to treat a man suffering with the pain of pleurisy, he has not fulfilled his duty when he has quieted the pain with an opiate, although the patient may take that view in his gratitude. In an hysterical aphonia or other paralysis, which is the essential condition calling for treatment—the immediate symptom which we know to be in a sense imaginary, or the underlying psychical depravity that allows of such self-deception? The clergyman to whom we have alluded, although somewhat emotional is really a man of good judgement and common-sense, yet he has been deluded into the belief that his life has been endangered, and his genuine gratitude to God and to his physicians is a matter of more or less ill-natured ridicule to those who know the true history of his case.

We fail to appreciate a striking difference between such methods and those of the advertising quacks who make a little more open use of the testimonials of their patients and who allow the latter to think that their illness has been of the most alarming nature.

Perhaps our meaning may be made plainer by a comparison to a purely moral question. Suppose that a child has appropriated a sum of money and, without calling his attention to the fact that a wrong has been committed, or without urging confession and reparation, we suggest to him the advisability of returning the money for fear he may be detected. To be sure, we have restored the proper financial level, but we have done nothing to reform the underlying dishonesty, and we have fostered a tendency to future wrong-doing. The proper moral management of such a child will occur to every right-minded person. In the case of hysterical manifestations we believe that the conscientious physician will endeavor not only to restore a functional equilibrium, but more particularly to bring about a realization of the self-deception which is one of the underlying factors in hysteria, and to develop proper physical stamina. We do not mean to imply that at the first visit the physician should bluntly say to the patient, "Your paralysis is all nonsense; nothing ails you except you are hysterical." Such a course would be as unwise as to call a child a thief for his first misappropriation of another's property. But with tact, gentleness and consideration for the patient's self-respect, the real nature of the hysterical manifestation should be gradually disclosed; self-control should be urged as the essential factor in a cure; and, without omitting proper medication, whatever suggestion is practiced should be made to a thoroughly conscious and responsible being, and not to one who is half asleep and wholly subservient to the will of the physician.

The Treatment of Diphtheria.

For the present the beneficial effect of the antitoxine of Koch, Behring, Kitasato, Roux, or, latterly, the serum of Risso, of Genoa, must be held *sub judice*. Heretofore the treatment has been mixed; that is to say, sole reliance has not been placed upon the new serum. Until such time, therefore, as we can avail ourselves of reliable reports from original sources of clincal application we should not discard what has proved of some benefit heretofore. In this sense the following is worthy of extended trial:

Acidi lactici pur..... ʒ;

Sig. Apply liberally to the membrane twice or thrice daily.

When this disappears, apply to ulcerated surface dustings of either iodoform or aristol powder. Constitutional treatment consists of large quantities of iron and milk.

Ecthyma Syphilitica.

M. Sig. Apply locally.

SOCIETY REPORTS.

AMERICAN MEDICAL ASSOCIATION.

Forty-sixth Annual Meeting, held in Baltimore, May 7, 8, 9, and 10, 1895.

First Day.

The first session of the Forty-sixth Annual Meeting of the Association was held in the Music Hall, on Mount Royal Avenue. It was called to order by the President, Dr. Donald Maclean, of Detroit, at 10:45 A.M. The opening prayer was delivered by Rt. Rev. William Paret, the Episcopal Bishop of Maryland. Governor Brown was to have delivered an address of welcome to the State, but was unable to be present. The members were welcomed to the city by the Han. F. C. Latrobe, Mayor of Baltimore.

Dr. Samuel C. Chew, Chairman of the Reception Committee, delivered an address of welcome on behalf of the medical profession of Baltimore.

Dr. Osler, Vice-Chairman of the Committee of Arrangements, made several announcements, urging upon the members the duty of registering early and reading the programme for the day's entertainments. He said that the guide-book which was gotten up for the benefit of the members, had been hastily printed, and the proofs had not been submitted to all the members of the Committee; had it been, some advertisements which it contained would not have been admitted. He desired to express his own entire disapproval of certain of them.

Dr. Donald Maclean delivered the presidential address, taking for his theme, "A Few Living Issues Affecting the History of Medicine and What Came of Them."

A vote of thanks was offered upon the conclusion of the address, and it was requested that part of it which deals with the question of the establishment of a National Department of Public health be brought to the particular attention of the Government at Washington.

The report of the Judicial Council upon the question of advertisements in the *Journal* was then presented. The Council found that some objectionable advertisements had been admitted into the *Journal*, and they had called the attention of the Trustees and of the Editor to the fact.

It was then moved that the repost of the Trustees be made on Wednesday, and be at once referred to a committee which should make its report on the following day. This motion was vigorously opposed, and a substitute was proposed that a committee be appointed to confer with the Trustees before the latter should make their report. The motions were laid on the table.

It was moved that the Genito-Urinary and Dermatological Sections be united, and the question was referred to the respective Sections for consideration and action.

Dr. Millard, of St. Paul, introduced a resolution to present a memorial to the Senate Committee on Naval affairs praying that the officers of the medical corps of the navy may have the same rank, pay, and emoluments as are now enjoyed by officers of the medical corps of the army. It was moved and carried that this resolution be printed and that a copy be sent to the President of the United States, the Secretary of the Navy, and every member of the 54th Congress.

Dr. Deartus Connor, of Detroit moved that a committee be appointed to determine what proportion of the members of the Association are accustomed to use proprietary remedies in their practice, and that, if it should be found that a majority did prescribe these drugs, all objections to the printing of advertisements in the *Journal* be withdrawn.

This motion, like all the preceding which had touched upon the question, was at once laid upon the table.

Second Day.

The meeting was called to order by the

President at 10.40 A.M. It was announced that a delegation from the American Pharmaceutical Association was present and the courtesies of the American Medical Association were extended to it. The chairman of the delegation was invited to a seat on the platform. The Nominating Committee was then appointed.

DR. ALBERT L. GIHON, U. S. Navy, then presented the report of the Rush Monument Committee. He said that he had regretfully to report that the amount thus far collected for this most worthy object was only $3,094.39. It was a subject of reproach to the American Medical Association that the necessary amount for a monument to Rush could not be raised, while in a much shorter time the American Surgical Association had collected all that was needed for a monument to Gross. The speaker said that he could guarantee that the pedestal for the monument would be furnished free of cost to the Association, a beautiful and most commanding site was already selected, and all that was now needed was that the Association raise the money for the statue. A number of those present offered to give personally, or to be responsible for the raising of, sums varying from $50 to $500, and before the next business came before the Association, the funds of the Monument Committee had been increased by over $2000.

On motion, the thanks of the Association were extended to Dr. Gihon for his unremitting labors on the Rush Monument Committee, and the report of the Committee was accepted and ordered to be published.

The reports of the Secretary and of the Treasurer were read and accepted. The Committee on General Business reported adversely on the proposed establishment of a seperate section on orthopedic surgery.

The Secretary read a communication from the Section on State Medicine containing suggestions relative to the establishment of a National Health Department, and calling for the appropriation of a sum sufficient to meet the necessary expenses of bringing the matter before Congress. The communication was referred to the Trustees.

DR. WILSON, of Columbus, O., offered a resolution urging the Association of American Medical Colleges not to rescind the rule of a four years' course of study which was adopted at the last meeting, and deprecating efforts which were being made to reduce this limit of study to three years. The resolution was unanimously adopted.

The Malarial Disorders of Large Cities, with Especial Reference to Chicago, was the title of an address by William E. Quine, M.D., of Chicago, Ill.

THIRD DAY.

The meeting was called to order by the President at 10.30 A.M.

The report of the judical council was presented. The protests against the registration of certain gentlemen from Pennsylvania and Ohio were referred to the respective State Societies. The report of the trustees was then read. The report said that hereafter no advertisements of medical preparations would be accepted for the *Journal* unless the makers published at the same time the formulæ of such preparations. On motion the report was unanimously approved.

Dr. C. A. WHEATON, of St. Paul, then read the address on surgery.

A resolution to raise the dues to $6, the extra dollar to be applied to the formation of a building fund was referred to the Business Commiitee. No amendments were allowed. On motion all the pending amendments to the constitution and by-laws were indefinitely postponed. The proposed amendment to the Code of Ethics, striking out the clause forbidding the patenting of surgical instruments, was likewise indefinitely postponed. The report of the Committee on Department of Public Health was then presented.

The Nominating Committee recommended the following for election: *President*, Beverly Cole, of California; *Vice-presidents*, Dr. Chisholm, of Maryland, Lagrange, of Texas, Clarke, of Mississippi, and Satterwhite, of Virginia: *Secretary*, Dr. Woodbury, of Philadelphia, Pa.; *Treasurer*, Dr. H. P. Newman, of Chicago, Ill.; *Address on Medicine* by Dr. Osler, of Baltimore, Md.; *Address on Surgery* by Dr. Senn, of Chicago, Ill.; *Address on State Medicine* by Dr. Rohé, of Baltimore, Md.

The next meeting will be held at Atlanta, Ga., the first Tuesday in May, 1896.

FOURTH DAY.

On motion, the thanks of the Associa-

tion were tendered Dr. Holton for his address.

DR. OSLER, of Baltimore, offered a resolution urging the members to rally to the support of the "Index Medicus," the publication of which was about to cease owing to the lack of funds.

A report was read from the committee appointed to consider the feasibility of the establishment of a benevolent fund. The successful and beneficent working of relief societies in New York and elsewhere was referred to, and it was recommended that a benevolent fund be established in the Association. On motion, the report was accepted and the committee was continued, with instructions to lay before the Association at its next metting a feasible plan for the creation of the proposed fund.

DR. WOOLLEY, of California, introduced a resolution that Congress be petitioned to retire paper money of small denominations and to limit the circulating period of bills of large denominations.

Action was then taken on the report of the Nomininating Committee. It was moved that the report of the committee be accepted, save those sections of it relating to the Secretary and to the place of meeting. Carried. It was then moved that the recommendation of Dr. Woodbury for Secretary be not followed, and that Dr. Atkinson, the present incumbent, be continued in office. Carried. It was then moved that the next meeting be held in Washington, in accordance with a previous resolution designating that city as the place for the celebration of the Jenner Centennial on May 14, 1896. After considerable discussion the recommedation of the committee was sustained and Atlanta was named as the next place of meeting, Dr. W. S. Westmoreland, of Atlanta, being chosen Chairman of the Committee of Arrangements, and Dr. J. McFadden Gaston, jr., of Atlanta, Assistant Secretary.

A proposed amendment to the Constitution was submitted abolishing the office of Permanent Secretary and making the office an annual elective one.

The Association adopted a resolution which had been submitted by the Association of Acting Assistant Surgeons, memorializing Congress to pass a bill placing those who served during the Civil War on the same plane as first lieutenants in the regular army.

The following were named as delegates to the meetings of Foreign Medical Societies: Drs. W. H. Daly, of Pittsburg; J. H. Ouchterlony, of Louisville, Ky.; I. N. Love, of St. Louis, Mo.; C. G. Chaddock, of St. Louis, Mo.; L. N. Montgomery, of Chicago, Ill.; A. E. Rockey, of Portland, Ore.; I. N. Quimby, of Jersey City, and H. H. Biedler, of Baltimore, Md.

Dr. Beverly Cole, the President elect, was then introduced, and made a brief address of thanks for the honor conferred upon him.

The meeting of the Association was then adjourned.

MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.

Business Meeting.

Forty-fifth annual session was held at Chambersburg, May 21 to 24 inclusive, 1895.

The meeting was opened promptly at 9 o'clock by Dr. John B. Roberts of Philadelphia. The opening prayer was offered by the Rev. Dr. J. Agnew Crawford, and the address of welcome was given by the Hon. John Stewart.

Some remarks were made on the business methods of the society by Dr. Roberts, the President. He said:

"Concentration of authority and responsibility is greatly needed. The trustees who are in the eyes of the law the legal representatives, do nothing except decide ethical and judicial questions. Consequently, the details of the business are entirely in the hands of the President, Secretary, Treasurer and the various committees. . . . Business principles seem to demand that the by-laws be amended so that trustees shall really be trustees, and meet at least twice a year at

fixed dates to supervise and direct the work of the executive officers, who should make regular reports. . . . Under such supervision county medical societies who had forfeited by suspension their right to representation, would not be likely to appear in the "Transactions" as still in good standing; nor would new county medical societies be admitted to membership without complying with your organic law. The delegations to the American Medical Association and to other State medical societies would be larger and more enthusiastic. . . . Limited membership, lax discipline, inefficient work and expensive administration are the sure results of the present methods. Lower assessment, greater membership, more enthusiasm, better scientific work, and higher public respect will follow the application of a sound business policy."

The society voted that a committee of five with Dr. Roberts as chairman, be appointed to consider amendments to the by-laws in accordance with the suggestions of the President.

Dr. William B. Atkinson, the Secretary, reported that Bedford and Snyder county societies had been revived.

The Treasurer, Dr. G. B. Dunmire, reported a balance of $2,300.38 in the treasury. A committee consisting of Drs. Strickler of Waynesboro, Beatty of Philadelphia, and Free of Jefferson, were appointed to audit the Treasurer's report.

Twenty-seven hundred and fifty volumes of the transactions of the last meeting were reported as having been printed at a cost of $1,551. Dr. Jackson suggested sending the volume direct to members of the societies rather than to the secretaries. Referred to a committee.

The report of the Committee on Scientific Business, relating to the reception, arrangement and disposition of papers submitted, was presented by Dr. C. W. Dulles.

The report on Pharmacy was made by Dr. Adolph Kœnig, of Allegheny.

A resolution requesting chemists to omit directions for use from catalogues of medicines, and requesting the statement of ingredients of remedies, was read by Dr. LeMoyne of Pittsburg.

The report of the delegation from the State Society to the meeting of the American Medical Association was made by Dr. Edward Jackson, who also read Dr. Cohen's report of the meeting of the Association in Baltimore.

The report of the Committee on Increase of Membership was read by Dr. C. L. Stevens. He also suggested the establishment of a committee of three, whose work it should be to increase county societies, and arrange lectures before county societies. An appropriation of $50 each for three years, for this committee was asked for. Dr. August Ehler of Lancaster, moved the adoption of the resolution, which was carried. Subsequently Drs. C. L. Stevens, Thomas Davis, T. S. K. Morton, G. L. Hull and A. C. Wentz were appointed the committee.

The report on Medical Examiners was read by Dr. H. G. McCormick. The report, which carried with it an appropriation of $500 for the expenses of aiding the Board in enforcing the law, was adopted. It was ordered that the names of the men licensed to practice should be published. The fact that 12 per cent. had been rejected by the Medical Examiners Board, led to the recommendation of a preliminary examination to determine the fitness of the candidate to take the studies requisite to the medical course

The report of Dr. W. M. Weidman, of the committee on the Rush Monument, read by Dr. Atkinson, showed that the fund amounts to over $5000. $2000 had been added during the year. $15,000 or $20,000 is necessary for the erection of a suitable monument to Dr. Benjamin Rush. The committee was continued.

The report on Contagious Ophthalmia was given by Dr. Howard F. Hansell. A bill is now before the Legislature, prepared by the committee, to prevent the many cases of blindness resulting from purulent inflammation of the eyes of new-born infants, by imposing imprisonment for thirty days and a fine for the failure of midwives or persons in attendance to report such cases to a physician or to the Health Officer. Discussion resulted in the report being adopted and the bill endorsed.

The report of the Legislative Committee on the Care and Treatment of the Insane, was given by Dr. I. C. Gable of York. The report was adopted and the expenses of the committee directed to be paid. The committee was continued.

An amendment to limit papers to ten minutes and discussions to five, was offered but was laid on the table.

An amendment was adopted, delegating the arrangement of the programme to the Committee on Scientific Business.

WEDNESDAY.

The following officers, nominated by the Committee on Nominations, were elected:

President, W. S. Foster, Allegheny. Vice-Presidents, Drs. John Montgomery, Chambersburg; A. P. Hull, Lycoming; T. H. Sharpnack, Greene; A. B. Brumbaugh, Huntingdon. Secretary, William B. Atkinson, Philadelphia. Board of Trustees and Judicial Council, Drs. D. W. Bland, Schuylkill; T. P. Simpson, Beaver; Henry Beates, Jr., Philadelphia.

It was decided to hold the next meeting in Harrisburg.

Drs. W. F. Skinner, T. H. Weagley, H. G. Chritzman and I. N. Snively were appointed delegates to the American Medical Association Meeting to be held in Atlanta, May, 1896.

The following resolution was passed, on consideration of the subject of Dr. Benjamin Lee's paper, "The Necessity for a State System of Registration of Vital Statistics in Pennsylvania; and submitted to the Legislature at Harrisburg," namely:

Resolved, That the Medical Society of the State of Pennsylvania considers the registration of births, marriages and deaths, at the Central Bureau of Vital Statistics at the Capitol of the State, a matter of the utmost importance in the interest of medical science, of public health and of protection to human life; and, therefore,

Resolved, That the Society respectfully memorializes the honorable, the Senate and the House of Representatives of the State of Pennsylvania, in favor of the passage of the bills introduced at the present session, to authorize the State Board of Health to employ a clerk for the registration of vital statistics; to confer the powers of a Board of Health on the school board of each township; and so to increase the appropriation to the State Board of Health as to enable it to efficiently discharge this important duty as assigned to it by law.

Resolved, That copies of the preceding resolutions, signed by the President and Secretary, be at once transmitted to the Hon. C. Wesley Thomas, President *pro tem.* of the Senate, and the Hon. Henry F. Walton, Speaker of the House of Representatives at Harrisburg.

On Wednesday evening, in Wilson College, was given the address of the President, Dr. John B. Roberts, on "The Present Attitude of Physicians and Modern Medicine towards Homœopathy."

This address presented in a semi-popular manner the differences between modern or rational medicine, and homœopathy, quoting the definitions given by standard dictionaries. Homœopathy as advocated by Hahnemann was described as a *school* of medicine, while non-sectarian medicine was designated as a *science*, since it is in no way founded on a theory or hypothesis but is the result of investigation of chemical, physiological and physical facts. The reasons were given which prevent physicians who subscribe to no dogma, accepting the doctrine of Hahnemann. The statement was made that many physicians who are called homœopathists by the public and who accept membership in homœopathic societies, are not believers in all of Hahnemann's theories. Long quotations were made from Hahnemann's "Organon" and recent homœopathic writers. These quotations showed that there are still some homœopathic physicians who believe in the increase of drug-power by diminishing the dose, and in the efficacy as a means of treatment of the so-called universal and infallible law of "similars." The attitude of physicians who accept no sectarian name was said to be a dual one. Some hold that homœopathists who do not believe in the universality of Hahnemann's law, should make a formal statement before being admitted to the right of consultation with members of non-sectarian medical organizations. Others believe that the profession and the public would be benefited if a gradute of a homœopathic college, or a member of a homœopathic society who simply indicates his willingness to treat patients by all means, should be admitted to the right of consultation.

The author did not indicate to which of these classes he belonged. The paper was not written in a controversial spirit, but seemed to indicate that the author desired to permit the hearer to draw his own conclusions as to the relative merits of the case.

THURSDAY.

Dr. H. S. Anders of Philadelphia, of-

fered a resolution to endorse the adoption of the individual communion cup. Laid on the table.

Dr. H. B. Guyer offered a series of resolutions requesting the Committee on Pharmacy to obtain from the Pennsylvania Pharmaceutical Society the formulæ of combinations found in the National Formulary and Pharmacopœia which are identical with, or similar to, the various trademarked preparations.

The society adjourned on Friday morning, after a short meeting, during which a resolution urging the State Board of Health to inspect vaccine farms was offered by Dr. I. C. Gable, of York.

TENNESSEE STATE MEDICAL SOCIETY.

Dr. G. B. Gillespie, M.D., of Covington, read a paper entitled

ANTISEPTICS IN OBSTETRIC PRACTICE.

(See page 732.)

DISCUSSION.

DR. J. BUNYON STEPHENS, Nashville: There has been a wonderful and aluable change made in the obstetrical ne during the last few years. I am satfied but very few of us follow the modern lan. I have found but very few that do. In order to practice obstetrics successlly, we ought to learn the alphabet of it. I consider the terms obstetrics and midifery are not synonymous; midwifery ing the art based upon a science, while stetrics includes both the art and the ience. In order to be successful obstetcians we have to be anatomists, physiolots, therapeutists and surgeons. The orough obstetrician is not only an anatnist, a surgeon and a therapeutist, but so a gynæcologist, understanding not only e diseases and accidents of pregnancy d of the puerperal state, but all the seases and accidents, with the treatment, new-born children. Unless versed in these points, one cannot be a successful stetrician; one can rise no higher than e level of midwifery.

Frequently we examine patients and do t have in view the points proper at the ne. For instance, we make an examinion and find, perhaps, the head of the ild presenting. We consider, and genally tell our patient all is right, sit down our dignity and leave the work to ture.

I believe doctors ought to advise their trons to call the physician early in obtrical cases. He ought to be called o, three, four, five or six weeks beforehand, and prepare the patient for parturition. In that way we could get rid of much of the puerperal troubles we have. Besides, there is time to rectify any misplacements of the uterus or child. I have said before, no man ever turned a chunk of wood floating in water easier than he can turn the child when well surrounded by the liquor amnii, and entirely by external manipulation, without even introducing the finger in the vagina. I say without hesitation it can be done, although not in every case, for sometimes the abdominal walls are too thick. Perhaps more than two-thirds of this audience would deny this, but don't deny it until you have tried it. Keep up the manipulations for a while, until you get the abdominal walls in good condition. As we learned in school, "if at first you don't succeed, try, try again." You will succeed in most instances where the abdominal walls are thin and the different parts of the foetus can be felt and it is easily movable. This is one important reason why we should be called early.

When called I would say it is best to take modern antiseptic precautions in every case. First of all, use a vaginal irrigation—not with the 1.4000 bichloride of mercury, especially when we irrigate the uterus, for with this solution there is danger of mercurial poisoning. The creolin solution I prefer to any other. This done just at the beginning of labor no more irrigation, in my opinion, is needed in a case.

Not only should we make digital examinations, but we should also make external manipulations. The digital examination is principally to diagnose the position of the child. Frequently we don't do even that. We should observe several points: the size of the pelvis; the condi-

tion of the soft parts of the genital tract; and what effect the pains are having upon the uterus. While doing this we should also settle the question whether or not the woman is pregnant. We have been called to the case, supposing she is. I have known doctors to wait all night and all day, until the old gray horse had almost eaten the top rail off the fence, and then discover the patient is not pregnant. We must take into consideration all the symptoms of pregnancy and of labor. Are the pains true or false? Then we look for the position of the foetus; and we should determine whether the position is all right, knowing how the six different steps of the mechanism of labor progress. We will not interfere if nature is doing the work all right, but if going wrong we must interfere. If acquainted with the function of the parts concerned and the different steps, then and then only is it possible for us to practice modern obstetrics.

As to the delivery of the after-birth. Simply wait until the uterus is ready to remove it. Someone said here to-day it is no credit to a doctor to have cases of puerperal eclampsia, the idea being it indicates lack of skill to have such cases. The speaker, I believe, limited that rule to the cases one had an opportunity to see before labor, and I agree with him. In the same way I say it is no credit for a man to have a case of post-partum hemorrhage, or of hour-glass contraction. We ought to have no case of post-partum hemorrhage—unless in one of those 'flooders,' of hemorrhagic diathesis, who would bleed to death if we only pulled a tooth. If we follow modern directions we will escape cases of post-partum hemorrhage. Now, unless we are cautious in the removal of the after-birth, we will have cases of post-partum hemorrhage to treat. All things being eqnal, it is best to use the Crede method of expression after the uterus begins its contraction, if you have no time limit. If post-partum hemorrhage is threatened, we should remove the after-birth as quickly as possible. Under ordinary circumstances we should wait five, ten, fifteen or twenty minutes; and then remove the after-birth, not by taking hold of the cord and pulling, but by squeezing it out as you would a seed out of a plum.

What then?

The essayest said that there is no need for continued irrigation, and the use of the antiseptic solutions and all that has a routine practice. I think such things only worry the women, as well as the doctor, and accomplish no good whatever. If there is nothing abnormal in the lochial discharge, I think we ought not be in such a hurry to follow out the routine plans we find in some of our books. The books may be correct, but there never was a successful doctor who was a book-worm only.

Dr. Menees, Nashville, delivered an address on some questions of obstetric emergencies. In obstetrics, emergency means as much as it does in surgery or elsewhere, and what has science done towards modifying and mastering them. There are emergencies of that character which o'er-leaps the boundaries of science, and demand originality. Who of you whose heads have been whitened by the frosts of the same number of winters as has mine, and been fanned by the storms of time, have not seen emergencies which could not be controlled by the slow and cold routine of modern obstetric science? I am going to relate some cases of emergency which I have encountered in the last few years. And while I claim to have some little reputation for veracity, I would not dare to risk that reputation in the statement of these cases without giving the names of living witnesses, who are, I trust, in the hall.

Some twelve or eighteen months ago, I was called by Dr. W. G. Ewing, in a case of gestation advanced about six or seven months. The condition was one of extreme exhaustion, and death looked inevitable, and that, too, in a very few hours. There was extreme nausea, utter nervous prostration, the stomach retentive of nothing, and not a labor pain nor the sign of labor pain. The patient was pale, lips blue, cheek pallid almost as death, pulse faint and feeble, scarcely discernible at the wrist; the eyes even growing dim in the hazy twilight of another existence. We agreed that she must be delivered, and that she must be delivered *at once*. Artificial labor must be brought on or she dies. Then the question arose as to how to bring on artificial labor. Had we ruptured the membranes and waited, she would have been dead a dozen times before labor came on. Had we introduced the bougie and sponge tent, she would not

have lived one-fourth of the time necessary for response of the uterus. What were we to do? A human life trembled in the balance of the answering of the question. I told you the patient was almost dead, relapsed, exhausted; and, although there was no uterine contraction, the relaxation of death being on her, the os, of course, was patulous, and easily and rapidly dilatable. It was decided that (after a very modern practice, which was suggested in a very recent work upon obstetric surgery, but which work I had not seen at the time, and do not believe it had seen the press, I proceed passing the finger into the os, succeeded with another finger and then another, etc., giving time for dilatation. It is a physiological fact that there is no muscle which will not yield to time and tension. I got the uterus dilated. And allow me to say anæsthetics should be used here if you can use them at all; and in these extremes always I prefer sulphuric ether. Don't use chloroform. After dilating, I was to proceed to deliver by forceps or by version, as the particular indication seemed to demand. In this case the delivery was accomplished fifty-four minutes after the beginning of dilatation.

But you may say that was resorting to the hated accouchement force of the French. Well, there is a great deal more bugbear in that name than there is in the operation in the hands of a man who has brains and knows how to manage it. You have all got brains: you can all manage it. One thing you should always be certain about, however, in emptying the uterus thus hurriedly, and that is the precaution to give ergotin before beginning to provide against post-partum hemorrhage.

Another case. Sometime in the last six or eight months I was called by Dr. J. S. Maddin, Jr., to a primipara, where repeated hemorrhages had already occurred. We were very apprehensive about adopting the tete-a-tete policy, but we did adopt it. The thing went on for a few weeks, when I was hastily summoned by Dr. Maddin, who had arrived in advance of me. A frightful hemorrhage had come on in advance of both of us, and the patient was very much exhausted from the loss of blood. Fortunately, before my arrival it was temporarily controlled. Only temporarily, however. Dr. Maddin and I agreed it would not do to leave the case or the next thing would be a fearful, frightful, it may be fatal, hemorrhage in our absence, and she would be dead before we could come. While we were talking the nurse said she was flooding again. There was no labor, no dilatation; the patient was about eight months pregnant. But in these cases of hemorrhage you will almost always find a relaxed condition of the uterus, the os more or less under your control and manageable. Dr. Maddin and I agreed the only safety to the patient was to empty the uterus at once. How? By bougie and sponge? She would be dead before she had time to respond to that. There is no use of talking about that kind of fox-fire or moonshine in this kind of a storm. Then, what? Deliver *at once*. And what does deliver at once mean? I will tell you what it means. I introduced Barnes' bag into that uterus. Dr. Maddin inflated it. It served most efficiently and expertly. Under the relaxation of the uterus there was no pain. I gave her ergot to bring on uterine contraction against the time delivery would have occurred. We left the first bag until it dilated to its full extent, and then put in a larger bag. I watched its effect, Dr. Maddin dilating it at intervals, until I thought I had the door open by which that patient's life might be saved. I ruptured the membranes and delivered the child, and the patient was saved. If we had tried any of tomfoolery, there would have been two funerals.

DR. W. K. SHEDDEN, Williamsport: Antiseptic precautions were referred to. I wish to say, that the gentlemen may not be mistaken, that at the Preston Retreat, Dr. Price did not use antisepsis with the idea of preventing disease of the mother, but simply to protect the child's eyes. He does not attribute the results in the retreat to the chemical antisepsis, but to asepsis and cleanliness and to the location of the hospital. He had a consecutive run of over thirteen hundred cases without a death from any cause. He did not have a case of puerperal sepsis during his entire service at the retreat. He condemns in every particular the use of chemical germicides under almost any and all circumstances.

Another thing I wish to mention is the treatment of puerperal infectious troubles. First, each of the writers have recommended intra-uterine irrigations. I be-

lieve, as has been remarked by Dr. Price, it does not make so much difference what you take out of the abdomen as what you put in there. I would fear more trouble from the injections than from anything else. The curette, in my opinion, is one of the most dangerous instruments that can fall into unskilled hands, or even, I will say, into professedly skilled hands. I had the opportunity of seeing Dr. Price make two operations for puerperal peritonitis, from the use of curette. He says it is of frequent occurrence in Philadelphia. If this is true, the intra-uterine use of the curette in the puerperal uterus certainly merits condemnation.

Again, gauze packing was in the papers. What can be hoped to be obtained by the gauze packing in these cases. If it is used for drainage, it will absorb until it is saturated but it will not allow any accumulated material to escape. You would have to remove and repack constantly if you did it for drainage. I have seen the pelvic cavity opened and abscesses laid open, and a regular duck's nest introduced, through which no drainage could be obtained. Further, it has been said that the glass drainage is not a surgical drainage. That view was presented by a gentleman for whose opinion I have very little regard, in this respect as in many others. One reason for that disregard of his opinions is due to the fact that recently, while performing an operation for pelvic suppuration in the German Hospital of New York, he opened the abdomen, found what he believed to be a pus-tube, laid it open, and lo! and behold, it was a pregnant uterus at three months.

Dr. G. A. Baxter, Chattanooga: I did not hear the papers but I heard Dr. Sheddan's remarks, to which I wish especially to reply. A reply by experience perhaps is best of all. Three days before leaving Chattanooga I saw an operation for perityphlitis, the omentum being diseased, gangrenous, and the abdomen was opened with the discherge of perhaps a handful of loose pus. That portion of the abdomen, after separation of the adherent intestine, was filled with gauze and cotton placed on it. The doctor said that gauze is not a drainage. That dressing had to be changed in twenty-four hours. That did not come through simple absorption, but through the gauze upon the outside dressing. Consequently there must have been a capillary attraction. It must act as a drainage.

One experience is worth a world of theory. When we speak of puerperal sepsis, we must remember there are two classes of poisons here. One is a simple intoxication, the result of the absorption of the ptomaines alone, without the presence in the system of a single germ. In a few hours after birth the temperature rises to 105 1-20 perhaps. You immediately look for the cause and the first place you look is your wound, in this case the womb. You use your blunt curette. Nothing may come away but a shred of membrane, an organized clot or piece of placenta, and yet in a few hours the temperature may drop down to entirely normal. In such a case the poisoning is from the germs in the womb, and your curette has done good, and flushings will do good. A scraping does no good, but a simple loosening of those detached pieces of membrane or decomposing putrifying pieces of placenta does good. Afterward your curette will do no good. The matter poisoning your patient is germinating now and the germs are being absorbed into the system. After they are absorbed the cause is already in the economy, and consequently all the scraping you can do will do no good. Here curetting would be an actual harm. We must draw this kind of a line between ptomaine intoxication and septicaemia. I believe no man can lay down absolute rules for every case of obstetrics. There is no reason why in certain classes of cases we cannot say it is possible to obtain puerperal asepsis and so you need no chemicals, because here is a case yon can protect from all external contamination. But first you must know that vagina contains no germs.

Dr. W. K. Sheddan, Williamsport: I believe my discussion was misunderstood. Dr. Baxter refers to experience. The reason I made the assertion I did was the fact of my obsevation. Having watched gauze packing and gauze drainage and having seen the results I detailed, was the reason I said what I did. But as far as septicaemia is concerned, I believe we can accomplish with the clean finger all that can done with any kind of a curette and without as much danger. The finger can be made cleaner than a curette, and much cleaner than most curettes used. Therefore I would do the cleaning with the

finger, an intelligent agent. You are not going to perforate the uterine walls with the finger, but this has been done with the curette.

As to the class of cases he refers to, I saw two cases of acute septicaemia, or what I call acute purulent peritonitis. The tubes were filled with pus. There were general adhesions, pus free in the peritoneal cavity, temperature below normal, pulse 170, and the abdomen greatly distended. There was also constant regurgitation, which could hardly be called vomiting. After a thorough washing out of the abdominal cavity, the freeing of all abdominal adhesions, trimming off from the mesentery flakes of lymph as large as my two fingers, I irrigated again with hot Schuylkill water, unfiltered but hot. After irrigating with some ten or fifteen gallons of that water, and the use of a glass drainage, the patient made an uneventful recovery, leaving the hospital five weeks afterward in perfect condition. In such cases nothing short of complete and thorough work offers the least chance.

DR. BAXTER: Why, if the peritoneum can be douched with unfiltered Schuylkill water, cannot the uterus be douched with unfiltered water?

DR. SHEDDAN: It can in some hands. But I wish to raise my voice against the curettment of every supposed case of puerperal infection. Dr. Price, during my stay with him last summer, with a record of more than 9,000 labor cases, says he never used a curette. He uses his finger. In hospitals I saw cases curetted, and the death rate was high. Dr. Price attributed it to the thermal heat. He gave the patients only a little saline, and no deaths followed.

With reference to symphyseotomy, its applicability, and so on, I wish the speaker had been a little more full in his description in this regard, and also as to whether craniotomy is ever justificable on the livng child. I do not believe it is. Also, I would have liked to hear him discuss the advisability of the Porro operation and Cæsarean section.

DR. MURFREE, Nurfreesboro, I believe the time comes when the placenta should be delivered. If by the natural process it is not thrown off, an interference is demanded. It is not right for us to sit by the woman's side and see the placenta remain 15 or 20 minutes or two hours. So long as it remains after delivery, it is a foreign body and likely to be a source of irritation and danger. It is right we should wait a proper time, until the uterus has time to contract and the placenta separate from the uterine surface. But we should not wait an hour and a half or two hours. We institute the Crede method; if it is not thrown off in due time, it is the modern obstetric procedure to introduce the hand and take it out. It is not necessary in such cases to wait long for nature to throw it off.

In reference to Dr. Menees' remarks I have but little to say. His accouchement force was referred to in the paper.

I would only criticise him for relying upon ergot or ergotin to relieve the post-partum hemorrhage. I have but little faith in it. I have infinitely more confidence with one hand on the inside and the other on the outside to produce contraction in post-partum hemorrhage, than upon all the ergot that could be injected. The irritation of the hand will produce a contraction of the muscles of the uterus.

In primapara Dr. Stephens spoke of accouchement force. There comes a question that is debatable. Is that the best plan to pursue? Or, it is better to rupture the membranes and tampon? In the accouchement force there is a forcible dilatation, and unless the emergency is very great we can better afford to rupture the membranes, and then by the vaginal tampon the hemorrhage can be arrested and the contracttion will take place and the fostus be expelled. That is done with much less damage to the woman's parts than with the accouchment forcé.

In reference to intra-uterine irrigation. I think there is danger of carrying poisons into the uterus; but, it is not necessary until a septic focus has formed, and that must be removed. Then we must hunt for the lesion, wherever it may exist, and remove it. It may be, possibly, in the vagina, and then the vaginal douche will wash it out. But is that fails we have no alternative but to go into the uterus.

The docter speaks of using his finger better than a curette. Well, some people may; and again, some might use the curette all right. But we should remove the microörganisms from the uterus, it matters not whether with the finger or

with the curette. The curette, it is true, has done harm, but that is no objection to the intelligent use of the curette.

How many times has the brain been impinged upon by the trephfs in unskillful hands? Does that condemn the trephine? No more do these cases condemn the curette. But be that as it may, the grand principle is to clean out the uterus and get rid of all septic fori and remove all irritation. The douche will not no it, because the microörgrnisns have burried themselves.

Dr. G. B. Gillespie, Covington (closing the discussion): I agree with what Dr. Murfree has just said, but I do not agree with Dr. Sheddan. I do not believe harm was ever done with the curette in the hands of a skilled surgeon, but I believe any harm that may result occurs in the hands of an unskilled surgeon. I pack with gauze, which I believe is a good drainage and the best we can use, and do not agree with Dr. Sheddan when he says it is not a drainage. Very seldom will you, in the treatment of these cases, have to deal with pus-tubes. Of course, if they occur, curetting will not remove them. I have operated a number of times and flushed the cavity with sterilized water without any harm to the patient. I have operated on a number of cases and never lost one. I have packed many times, but never needed to repack. The patient always made a rapid recovery.

As to removing the placenta, I believe in waiting only a short time, five to ten minutes. It is unnecessary and probably do harm to wait longer.

"Hygiene of Circumcision."

Read by W. Frank Glenn, M.D., Nashville.

(See page 733.)

DISCUSSION.

Dr. C. R. Atchison, Nashville: I am an inveterate enemy of the prepuce. Why it should still cling to us I am unable to state. In olden times, when men relied upon the fig leaf for their protection, and chased game through the underbrush, and perhaps, through the briars, this leather pouch was, perhaps, a good protection. But now, since we have become civilized and wear clothes, we certainly could do without it. The Hebrews have practiced circumcision from their beginning as a race. As a result you find few inmates of asylumns and few drunkards among them. The reflex neuroses which can come from it certainly are many. It increases the sexual appetite. It is the cause of many diseases. The prepuce should be taken off. Not in all cases, for nature partly attends to it in an abnormally small one; but, wherever it is pendulous, I believe it should be removed.

Dr. T. J. Happel, Trenton: The operation I have often performed, not in the child but in the adult. Had it been done in the child, it would not have been necessary in the adult, because the disease which rendered it necessary would not have existed. In every family every male child should be circumcised. It is a truth which cannot be controverted, that you don't find Jews in work-houses, jails, or asylums. This must be accounted for by some pecularities of the race, and there is nothing more strongly marked in the Jewish race than the practice of circumcision. In this way they are protected thoroughly from disease. A nasty, long prepuce acts as a suction to draw in gonorrhœal fluid, loaded you say with microbes—with poisons. Many boys, for this reason, contract diseases which otherwise they would not contract.

Dr. W. I. Scott Dixon: I see the profession is in favor of severing as many as possible of the parts of the body. They said at Memphis, the vermiform appendix is unnecessary; now they say the prepuce is unnecessary. We don't know, yet, how far the Lord erred in making man.

Dr. J. B. Gowan, Tullahoma: I want to ask Dr. Glenn a question. Is it not a fact that in every instance where there is a prepuce which cannot be withdrawn over the glans, we have a masturbator? Does not the irritation produced by the long prepuce and the failure to retract, act as a factor in causing masturbation?

Dr. Glenn: I have not statistics as to every case, but I believe it has a tendency in that direction.

Dr. Cowan: I heard Dr. Glenn read a paper before, on a similar subject and I have always considered him an authority on it. and have for many years advocated circumcision in boys, every time and at an early age. The longer we defer it, the greater the danger. The neuroses from the irritation of the long prepuce, were

referred to a while ago. We have a work on that subject, *Psycopathic Sexualis*, but in it the fact is missed that where they have not the power to retract the prepuce we always have the conditions that have been described. I am glad that Dr. Glenn said what he did about the operation being done in the lying-in room. I believe it should be done there, and if he neglects it and anything occurs afterwards, the physician should be held accountable for it. I have never in my life seen a boy that couldn't retract the prepuce, but what was a masturbator.

DR. GLENN: Did you ever find any boy that was not a masturbator?

DR. COWAN: Well, I think I have. I will qualify that remark. I think I have found boys who were not masturbators; I mean excessive masturbators, of course. One of the saddest cases I have ever known was in a very bright boy. He conceived trouble, and by a mere accident it was discovered. The prepuce was removed and he obtained sufficient mastery of himself to control himself. I believe we commit a sin by not examining all cases.

DR. N. C. NEWMAN, Normandy: I am in favor of circumcision for the reasons stated by the essayist. We don't see the Jews in our workhouses, jails and county asylums, and you want to lay that now to the fact they were circumcised. But I don't lay it to that. God said the Jews were His peculiar people. He said again, salvation was of the Jews. We have a book called the Bible, not a word of which but was written by a man inspired, not a Jew. When God had said the Jews were His peculiar people on the earth, and they were being destroyed by the armies and nations around them, He said to the Jews, "I will make an end of the nations that destroy thee, but I will make an end of you." The nations around them were destroyed. The Roman armies are of the past. There is not a drop of Medo-Persian blood on the earth. According to that prophecy, to-day we find Jews, hundreds and thousands of them, whose blood is as pure as that which flowed in the veins of Abraham. Now, gentlemen, don't attribute all this to the fact they have not the foreskin. Remember the hand of God has guided them. They have the record, to-day, of an unbroken lineage.

DR. ROBERTS: I will not go so far as Dr. Cowan, but I will say this, conscientiously and honestly, that I have never yet been consulted in a practice of more than a third of a century, by any one for the effects or results of masturbation but I found an elongated prepuce. So far as my memory will go, in proportion to the number of Jews who have consulted me, I have found among them less of the communicable specific diseases than I have in other races. As regards the terrible vice which so often makes a wreck of a young man's life and makes him worse than the inmate of a tomb, in no instance have I been consulted but I found circumcision was necessary.

DR. SHEDDAN: I would like to ask a question. The necessity of doing the operation in the lying-in room has been suggested. I would like to know whether it is possible to deliver a woman in the country or not. I suppose it is necessary to have an ophthalmologist to prevent or remove this appendage; and, I suppose, an abdominal surgeon to remove the vermiform appendix.

DR. GLENN, (Closing the discussion): I have studied this question a number of years, but I am afraid some of the members do not see it as I do. I think the damages done between the ages of twelve and eighteen years by excessive masturbation are little appreciated by ninty-nine out of a hundred people. It has become so common. The nervous weakness, the neuroses, the mental weakness, the premature old age, which can be attributed to sapping the individual when he needs his strength the most, I think is not fully appreciated. I firmly believe and freely say we should not stand by and say, "Of course, every boy must masturbate; of course every boy has gonorrhœa; and of course every boy has intercourse; that is all right. We should say, "It is wrong. It is wrong for your health; it is wrong for your mind; it will make more criminals, and therefore they should not have an emission, as physical men, until they are grown." The nervous system should be nurtured and the habits regular until the man is grown, until nature has made him ready to perform the functions of a man; and then he remains a man with the nature of a man, and is able to put passion under him and is not to be guided by his passion. I know of an instance in which a man was a raiser of thoroughbred horses

and had a number of stallions. He would allow no stallion to cover more than two mares in twenty-four hours; one in the forenoon and the other in the afternoon; and yet that same man would go to a house of prostitution and would have intercourse six or seven times in a night. He came to me with weakening. He said, "I used to have intercourse six or seven times in a night; now I can only have it three times." I said, "Do you know what I would recommend?" He said, "No." I said, "Castration. You will not allow your horses to have intercourse more than twice a day, and yet you have intercourse several times in that time."

We do not appreciate the injury to the race that the subversion of the sexual function as a slave to passion, is. I regard the sexual devolpment as the height of creation, from a highly hygienic standpoint, not as a degraded passion. I think God stamps His wisdom in the regenerative function. Sap the sexual function and you sap the individual's life. However fat and well he may look, he knows he is not the man he was; he is not the man he should have been. We should look to the removal of the prepuce as the remedy in many cases. An unknown trouble, as when a little boy is unruly and restless and nervous and his mother cannot control him, may be due to an irritating prepuce. I have known, as you have, after circumcision in such cases, a thin child will become a big, fat, bouncing fellow and healthy. Whether God made a mistake or not, I do not know. Whether Moses was an inspired man or not, he said he was, and God said he was; and Moses said the boy should be circumcised.

I failed to do it in the case of my own boys when they were born, but I will do it now in one of them when school is out. I use the plainest talk to them about gonorrhœa and syphilis. Then I teach them to come to me if anything occurs wrong, as the one to trust implicitly. I believe many boys get into the habit through ignorance, and continue it through ignorance. The first fire they have often is engendered through the quack circulars circulated around the country. I have had them come to me with that statement. I believe the chief object in Moses recommending it was to prevent this habit. It also prevents, largely the contraction of syphilis. Also, if syphilis or gonorrhœa is contracted, it enables the surgeon to treat it much more easily.

I do not want to be considered a radical crank, but I do not believe there is any one thing could be done that would exercise as great influence on the race as the circumcision in infancy of every male child that is born. This wetting of bed, in boys, is often dependent upon a long, irritating prepuce, and they get well as soon as you circumcise them.

Chordee.

In a paper on "Local Anesthesia," Dr. Wm. P. Carr, of Washington, D. C., writes, *Med. Bulletin:* "In this connection I may mention a fact well worth knowing, and I think not generally known, that chordee may be entirely and promptly relieved by putting on a condom containing two or three drachms of a two per cent. solution of carbolic acid, and that any pain in the penile portion of the urethra or pendulous penis may be controlled in this way."

Diet in Diabetes.

Dr. Charles H. Ralfe gives (*Clin. Jour.*) the following:

Pure Gluten flour..... (Or instead wheat flour)....	12 oz
Animal food (fish, meat, poultry).....	16 oz
Green vegetables.....	14 oz
Fatty matter (butter, cream, bacon).....	12 oz
Miscellaneous (eggs, cheese, Iceland moss, etc.).....	14 oz

About liquids the safe rule as Dr. Ralfe recommends, is to allow ingestion to exceed excretion by about twenty ounces.

Neurasthenia.

The following was a favorite prescription of Sir Andrew Clark for various kinds of neurasthenic debility:

Acid phosphate.....	ʒj
Ext. cocæ liquid.....	ʒss
Ext. damian. liquid.....	ʒss
Tr. nucis vomic.....	mx
Syrup. zinglb.....	ʒj
Aquae, ad.....	ʒss

Ft. dosis.
Sig. To be taken in water at 11 A.M. and 6 P.M.

PERISCOPE.

IN CHARGE OF WM. E. PARKE, A.M., M.D.

MEDICINE.

Absorptive Power of the Vagina.

Coen and Levi have recently made some observations on the absorptive power of the vagina under various conditions of health and disease. Iodide of potassium is easily absorded. If a tampon soaked with a 20 per cent. solution be introduced into the vagina, iodine can be found in the urine in an hour. The excretion reaches its maximum in twenty hours. Fever and pregnancy increase the absorption. Hysterectomy makes no difference. Iodoform is absorbed slowly and in very small quantities, but more if fresh than if old. Salicylic acid is absorbed quickly, appearing in the urine in one hour and disappearing in twenty four hours. Salol is very readily absorbed. Antipyrine is execreted in an hour and a-half and is found for forty-eight hours, but its antipyretic action is feeble as compared with administration by the stomach. In brief, the vagina has undoubted absorptive power, and this is increased in pregnancy, in the puerperal state and pyrexia.—*North American Practitioner.*

Artificial Respiration in Cerebral Compression.

Horsley has shown that death, in cases of compression of the brain, whether from cerebral hemorrhage, fracture, and depression of the skull, or tumor of the brain, is due to failure of respiration. While permanent relief can be obtained only by a surgical operation in these cases, temporary relief, by which a patient may be kept alive, may be obtained by means of artificial respiration, which should be employed even in the most desperate cases. Hot fomentations should also be applied to the head, or hot water may be poured upon the head. Mr. Horsley is utterly opposed to the application of ice to the head.—*Mod. Med.*

Vinegar Inhalations to Relieve Vomiting after Chloroform Anæsthesia.

The inhalation of vinegar by means of a compress wet with ordinary vinegar placed over the face of a patient, is in use in McEnrode's clinic at Berlin, as a means of relieving the vomiting after chloroform anæsthesia. It is also successfully used in other continental clinics. The favorable effects of the vinegar are claimed to be due to the stimulating action of acetic acid on the respiratory organs, and the combination of the acetic acid with the chlorine exhaled from the lungs as the result of the decomposition of the chloroform, whereby it acts as an antidote. The inhalation should be continued until the nausea disappears.—*Mod. Med.*

Accidental Swallowing of a Stomach-Tube.

Landstrom describes such a case (*Hygeia*) the patient being a seamstress who was performing lavage of the stomach for round ulcer, and who swallowed a portion of the tube, forty-eight centimetres long and eleven centimetres wide, solid and somewhat inelastic. She fainted, and for some days after suffered from severe, bloody vomiting, nausea, and intense pain at the pit of the stomach and in the bowels. She was unable to take any nourishment. Eight days later Landstrom detected the foreign body, doubled on itself, in the iliac fossa, immediately above the centre Poupart's ligament. Laparotomy was performed by Ekehorn, and the tube was found in the ascending colon, the torn end being clearly seen through the intestinal wall. A longitudinal incision of three centimetres was made in the bowel, the tube extracted, and the incision sutured with fine silk threads, two rows being placed throug the muscular and serous coats, and another row through the abdominal wall. An aseptic bandage was applied and the patient recovered from the operation without incident.

The Absorption of Pleuritic Effusions After Hypodermic Puncture.

Dr. F. Jordan (*Allg. med. Central-zeitung*) draws attention to a new procedure, which on account of its simplicity and harmlessness, deserves to be better known and studied. Jordan, in investigating the therapeutic effect of various surgical measures on pleuri-effusions, noticed that the quantity of urine increased very considerably after having made an exploratory puncture with a hypodermic syringe. This observation he made in the first instance on four patients, and not being able to account for the increased flow of urine in any other way except as the result of the exploratory puncture, he repeated the process on fifteen other pleuritic cases, with the same result. The quantity of urine, which before the operation had amounted to 200-800 c.cms., increased after it to 2,000, or even 5,000 c.cms. This diuretic effect showed itself about two or three days after puncture, but sometimes not until the eighth or ninth day, and continued until the whole of the effusion had disappeared. Twelve of the cases were chronic, with serous effusion, and three acute (two serous and one hemorrhagic). The amount of the effusion was in all cases "more than mediumly large," and in two it reached to the second and third ribs respectively. The diuresis was accompanied by an abatement of the temperature. It took on the average about two months to complete recovery. In one of the acute cases with large effusion, five weeks after the operation only traces of the effusion could be

discovered. Jordan does not give any satisfactory explanation of the *modus operandi* of the procedure.

Milk Diet in Typhoid Overdone.

Da Costa thinks the exclusive milk diet is a source of mischief rather than good, and recommends three parts of milk alternated with one broth. He, however, evidently does not recognize the fact that the latter has scarcely any food value, the little extract of meat it contains acting solely as a stimulant, and, moreover, with a great tendency to cause flatulence. It has on several occasions been pointed out that whenever curd can be seen in the motions, too much milk is being given, and it may even indicate that it is not being digested at all. It is best replaced by white of egg beaten up and largely diluted with water; in this way can be introduced any requisite amount of real food, and in the blandest and most readily digestible form; it leaves no solid residue, and can cause neither diarrhœa nor gaseous distention.

For Obesity.

Take no water or other fluid at any time, except one cup of any desired hot drink, just before rising from the table. Use no liquids while eating. Avoid sugar, nuts and pastry. Eat nothing between meals. Confine the diet to lean beef, mutton, chicken, turkey, fish, eggs, oysters, with one slice of stale bread well dipped, the bulk of the meal being of tomatoes, celery, spinach, turnips, cabbage leaf, but not the fleshy mid rib, and fresh or dried fruits, cooked without sugar, such as apples, peaches, plums, prunes, prunellas. A little cheese is permissible; coffee, tea, skimmed milk or buttermilk after eating as stated. Exercise should be taken, running being most effectual, before breakfast or before going to bed.

A Rare Form of Total Cystic Degeneration of the Liver.

Z. Dmochowski and W. Janowski (*Beitr. z. Pathol. Anat. u. Allg. Pathol.*) describe an enormously enlarged liver, measuring 40 by 33 by 18 centimeters, and weighing 10,850 grammes, composed entirely of a collection of cysts, so that almost no normal liver tissue was to be seen. The kidneys were similarly affected. The liver cysts varied in size from a pin's head to a small cocoanut; they were filled throughout with a clear fluid containing plates of cholesterin, some of them colored by the bile. Microscopic investigation revealed an enormous increase in the connective-tissue of the liver. The cells lining the gall-ducts were intact. Many of the cysts, both large and small, had thick connective-tissue walls; in the larger ones the epithelium could not be seen: in no case were broken-down partitions found. The liver cells in the neighborhood of the cysts were much distorted by pressure.

According to the authors, this is a case of primary atrophic liver cirrhosis, with secondary cystic fibro-adenoma, which began in the bile-ducts.

NEWS AND MISCELLANY.

The semi-centennial of the Ohio State Medical Society was held in Columbus, May 15th, 16th and 17th. The meeting was the largest in the history of the society, there being about five hundred in attendance. Also, there were more new members received than at any previous meeting, one hundred and four being added to the list.

The election of officers resulted as follows:

President, Dan Milliken, M.D., Hamilton; Vice-Presidents, J. H. Goss, M.D., Lancaster, William H. Humiston, M.D., Cleveland, John W. Murphy, M.D., Cincinnati, B. M. Ricketts, M.D., Cincinnati; Secretary, Thomas Hubbard, M.D., Toledo; Assistant Secretary, H. M. W. Moore, M.D., Columbus; Treasurer and Librarian, Jas. A. Duncan, M.D., Toledo.

STANDING COMMITTEES.

Finance, J. G. F. Holston, M.D, Zanesville; Ethics, J. C. Reeve, Sr., Dayton; Publication, R. Harvey Reed, M.D., Columbus; Legislation, Geo. A. Collamore, M.D., Toledo; Admissions, A. B. Richardson, M.D., Columbus.

Deer Park on the Crest of the Alleghenies.

To those contemplating a trip to the mountains in search of health and pleasure, Deer Park, on the crest of the Allegheny mountains, 3,000 feet above the sea level, offers such varied attractions as a delightful atmosphere during both day and night, pure water, smooth, winding roads through the mountains and valleys, and the most picturesque scenery in the Allegheny range. The hotel is equipped with all adjuncts conducive to the entertainment, pleasure and comfort of its guests.

The surrounding grounds, as well as the hotel, are lighted with electricity. Six miles distant, on the same mountain summit, is Oakland, the twin resort of Deer Park, and equally as well equipped for the entertainment and accommodations of its patrons. Both hotels are upon the main line of the Baltimore and Ohio Railroad, have the advantages of its splendid Vestibuled Limited Express trains between the East and West. Season excursion tickets, good for return passage until October 31, will be placed on sale at greatly reduced rates at all principal ticket offices throughout the country. One-way tickets, reading from St. Louis, Louisville Cincinnati, Columbus, Chicago, and any point on the B. & O. system to Washington, Baltimore, Philadelphia or New York, or vice versa, are good to stop off at either Deer Park, Mountain Lake Park or Oakland, and the time limit will be extended by agents at either resort upon application, to recover the period of the holder's visit.

The season at these popular resorts commences June 22d.

For full information as to hotel rates, rooms, etc., address George D. DeShields, Manager, Deer Park, or Oakland, Garrett County, Md.

FURTHER OBSERVATIONS ON THE OPERATION OF EXCISION OF THE MEMBRANA TYMPANI AND OF THE OSSICLES IN NON-SUPPURATIVE (CATARRHAL) INFLAMMATION OF THE MIDDLE EAR.

LAURENCE TURNBULL, M.D., PH.G.,* PHILADELPHIA, PA.

In our former papers † we, perhaps, did not dwell sufficiently, upon the subject of drainage but as we are dealing with the first form dry, non-suppurative, mainly, the great importance of drainage need not interest us so much as when we come to the suppurative from of middle-ear inflammation. We have never had a persistent discharge to follow our operations, but we have had it so stated where it occurred in the hands of others.

In advising this operation it is well to explain in detail how little may sometimes be gained. Yet how important that little of hearing may be, is shown by the entire relief from vertigo, prolonged pain and tinnitus, or by its sudden loss. Again where deafness is progressive, *i.e.*, to judge from cases already observed, the progress of chronic inflammation may cease after the mucous membrane of the drum undergoes dermic transformation.

We have been forced to the conclusion that on the removal of the drum head malleus and incus, sound enters the labyrinth through either or both windows, since we have witnessed great improvement from an opening made in the drum head without separation of the incus from the stapes. But no way is at present known of ascertaining beforehand absolutely, except those before given in our paper, whether fixation of the stapes exists in any given case.

The writer's experience in operating for the relief of subjective symptoms only is limited. It has been found, however, that where there existed vertigo and noises in the head, they have been alleviated or cured entirely by excision. Where very great relaxation of the transmitting mechanism exists, giving rise to severe autophonia, noises, vertigo, etc., the operation would seem to be indicated. As a rule it is probable that the earlier in life, as well as earlier in the disease itself, the operation is done the more successful it will be.

The author has found that the chorda tympani nerve is usually not disturbed by this operation, especially where it is possible remove the incus first. If, however, it happens to be drawn down into view a section of it may be removed, the result-

† Vide MEDICAL AND SURGICAL REPORTER., current vol.

ing disturbance in taste being of short duration. Where the incus cannot readily be found, protracted search should be avoided, since its retention could not be productive of so much harm as are rude attempts at removal. Experience, moreover, shows that the removal of the incus is not absolutely necessary to a favorable result of the operation.

The parts should be carefully cleaned with absorbent (iodoform) cotton after the operation, or packed with iodoform gauze. There is but little if any pain experienced by the patient on coming out of the narcosis, and a drop or two of a 10 per cent. solution of cocaine is sometimes sufficient to allay any discomfort. Syringing is not advisable, as a rule. It is necessary to practice antiseptic precautions in this operation, as in all operations on the ear, either internal or external. In and about the ear the parts should be well washed with green antiseptic soap, after which with a solution of bichloride of mercury (1-2000), then with ether in which soap has been dissolved. The hands, and especially the nails, should receive close attention. All the instruments should be dipped in hot 1 per cent. solution of carbolic acid and soda before using. When operating this solution should be kept hot by a spirit lamp.

In five or six days, any tissues left partially detached during the operation and which has become necrotic, if not discharged, should be removed. The quantity is usually very small, consisting only of shreds of tissue. Chiselling away a portion of the sulcus tympanicus is quite unnecessary, indeed the procedure is, from the irritation caused, likely to favor reproductive action.

As result from exposure in very inclement weather decided suppuration may go on. This has to be promptly treated with equal parts of powdered anti febrin and boracic acid.

Extreme care should be taken in all cases to prevent suppuration, and irritation of the parts in any way prevented. Some cases need not be even wiped out, the slight discharge being allowed to become inspissated. Crusts are thus formed in the end of the canal and over the margin of the remaining rim of the drum head; the fundus gives the appearance of having been closed in by reproduction. On finally detaching these crusts, sometimes a large opening will be found. After healing has taken place the mucous membrane undergoes dermoid transformation, its sensitive mucous surface having disappeared.

Dr. Sexton* found operation was more successful, as regards maintaining an opening in the drumhead, in persons of light build and in those who were not given to the use of stimulants or the consumption of a large amount of meat.

Referring to the recent work of Dench, in this operation, or any intra-tympanic operation, I find that he considers it always necessary to use a general anæsthetic except for the division of adhesions, and in his cases even where no discharge is present he advises a douche of a solution of bichloride of mercury 1—5000 several hours before operating.

We, usually, have operated on a couch, bed, or ordinary reclining chair, with the patient on the side, the head elevated on a pillow, while the operator seats himself on a level with the ear to be operated on. The anæsthetic is given in this position and the patient kept quiet, and disturbed as little as possible. Our author considers the position as a matter of no little importance, as effecting the result of the procedure. As the operative field is extremely limited, the surgeon should avail himself of every means in his power to have the head in such position that he can easily see all parts of the tympanic cavity and conduct his manipulations without the necessity of assuming an uncomfortable position. To this end he "now operates with the head and shoulders well elevated, the head being supported upon a rest which admits of motion in all directions. The patient is anæsthetized in the recumbent position annd after thorough etherization is raised to the desired posture upon the German head-rest. Elevation of the head and shoulders also diminishes the hemorrhage, and the blood instead of flowing into the upper and posterior portion of the fundus of the canal in the region of the incudo-stapedial joint, is directed to the floor of the canal, and hence does not obscure that portion of the operative field which demands our closest attention."

"Straps passed under each arm prevent the body from falling downward during the operation." [I am always afraid of

* Report of the New York Ear and Eye Infirmary; also in his recent work on the ear.

this position in the use of general anæsthetics.]

Some writers, notably Sexton, remove the incus before the malleus, and if the long process of the ossicle can be easily grasped after the incision of the membrana has been completed, there is no objection to this being done. Of late, however, Dench has stated that he has almost invariably extracted the malleus first (as we have here recommended,) and he finds the procedure less difficult than the other. If the incus has passed beyond the line of vision it can usually be brought into view by means of the incus hook. "These hooks are curved in opposite directions for the right and left ear, and are to be inserted into the handle in such a way that the hollow looks anteriorly; this hook is inserted into the posterior portion of the tympanum and being carried behind the ring, is then swept cautiously forward through the fornix, very little force being used. In executing this manipulation the hook should be kept in contact with the tympanic ring by gentle traction outward. In this manner it is usually possible to bring the long arm of the incus into view, presenting it close to the margin of the ring and being easily recognized; the difficulty in finding the incus frequently arises from the fact that we are inclined to search for it too high up, and too deeply in the cavity; the previous removal of the malleus usually loosens the attachments of the incus and allows the ossicles to fall somewhat backward and downward; it moreover, usually hugs the margin of the ring closely, and often at first seems to belong to this structure, but a touch with the probe or hook will push it further into view and reveal its true nature."

Our author is of the received opinion that it is better to avoid the removal of the bony ring, if possible, when the stapes is concealed behind the margin of the ring. If found rigid, incisions should be made around its base, then by gentle pressure with the cotton-tipped probe, applied at first below and later at its outer border, so as to render it more movable. This procedure has been carried out by Boucheron, Miot and others, when he considers it advisable to remove the stapes, and this we consider very rare, it can be extracted either with the forceps, or better by means of a blunt hook passed between the dura after dividing the attachments about the foot plate. He packs the ear with antiseptic gauze, but in a few hours this is removed and the ear syringed with a weak antiseptic solution, a saturated solution of boric acid or a bichloride solution, 1–5000 being used, and the gauze is replaced. Upon the following day the gauze is dispensed with and the patient is ordered to douche the ear with the antiseptic solution, twice or three times daily according to the amount of the discharge. Too much douching is highly objectionable, the purpose being only to keep the parts cleansed.

We most strongly object to this douche, as it prevents the prompt healing of the wound and tends to produce a moist condition and discharge. For this later free discharge he has to resort to another agent, a solution of boric acid in alcohol being dropped into the ear after each douching. He is not afraid of a 10 per cent. solution of cocaine, which he employs, as do we, in excising the new membrane, which he keeps in contact with the membrane for a few minutes. In making this section, which he does several times if necessary, he differs in his methods as follows:—The section of the extra membrane is made first with a sharp pointed knife and completed with a blunt one. When half of the circumference has been divided, the relaxation of the membrane makes the completion of the section difficult. This he states may be overcome by making a second puncture close to the original starting point, and completing the section by carrying the knife in the opposite direction. The fragment is then held at two points only and is easily detached with the forceps.

In plethoric patients he considers it necessary that the diet should be restricted for a few weeks before and after the removal of such a membrane, and he thinks this aids very much in preventing complete closure of the artificial opening. In conclusion he states:

"In the technique of the operation I am aware that I have differed somewhat from other writers. In the division of the incudo-stapedial articulation, I prefer to press the shaft of the knife closely upon the antero-internal aspect of the long process of the incus and cut downward, completing the division if necessary by cutting from below upward with the point

of the instrument, rather than pressing the knife against the posterior aspect of the long process of the incus, as is often advised. My reason for this is that the field of operation is in much better view in the former case than in the latter.

In removing the incus, the method described is the reverse of that advocated by Kretschmann (*Archiv für Ohrenheilkunde*, vol. xxv., p. 192), who was the first to formulate this procedure. This surgeon devised an incus hook with a double curve, the distal extremity being cup-shaped. To remove the incus, the bent part of the instrument was carried into the fornix, the distal extremity looking backward. Rotation of the instrument backward upon the axis of the shaft, carried the cup-shaped end of the hook over the short process of the incus, thus bringing the ossicle into view. In my hands, this method has not succeeded as well as using the simple hook already mentioned, and carrying it in the opposite direction. It certainly would seem that backward rotation would be more likely to dislocate the ossicle into the mastoid antrum, than manipulation in the opposite direction."

TRIONAL: ITS RANGE OF APPLICABILITY.

SAMUEL WOLFE A.M., M.D.,* PA.

In casting about for an hypnotic we have the ideal in view. We look for a substance which while easily administered, will promptly produce sleep in all respects like the normal and for about the normal period, and which will make no deleterious impression upon the system in any way.

So perfect a drug would imply, so to speak, a perfect pathology of the symptom, insomnia. That this is more true in an abstract sense than is generally admitted, I am inclined to believe. Whenever that portion of the nervous system involved in the maintenance of consciousness is active when in the normal course it should be inactive, the immediate cause, if the physiological theory of sleep is correct, is the continuance of too active and too voluminous a blood supply to the tissues concerned.

A drug that will regulate this disturbance will prove a true hypnotic. That its power to do so will depend largely on the given cause of the hyperæmia, is a foregone conclusion. Where fever and pain are absent or trifling in degree, Trional and other drugs of the same class seem either to reach the cause or in some other way abolish the symptom. That they do it by overcoming the hyperæmic condition rather than by directly stupefying the cortical cells is, from the observation of the normal quality and quantity of the sleep produced, a rational conclusion.

The superiority of Trional in promptness, ease of administration, and absence of bad or disagreeable after-effects, over most, if not all, other hypnotics, seems fairly well established.

When a dose of fifteen grains is given, sleep usually ensues within a half hour, if at all, and this result seems but little altered whether the drug be administered in a warm vehicle (it does not readily dissolve), or given as a dry powder, or in capsules. It is indeed often so prompt that the patient sleeps within a very few minutes after injection. The dose in some cases must be larger than fifteen grains, although I should not advise more in any case unless the susceptibility of the patient had been first ascertained and in many cases I believe ten grains would prove efficient. It may be safely repeated at least once in a night, and in an hour if necessary.

As to disagreeable after-effects, some of my patients have complained of a feeling which they are hardly able to describe, but while it may be an approach to vertigo, I gather it is rather more closely akin to the sensation which is experienced when we are obliged, though intensely sleepy, to keep awake for some reason not very forcible or agreeably stimulating. It has usually oc-

* Physician to the Philadelphia Hospital, Neurologist to the Samaritan Hospital.

curred when proper composure and disposition of the body has not been attained in time to yield freely to the effects of the drug. A feeling of drowsiness during the following day has in a few instances out of quite a large number of observations, been noted. This again is very much like the feeling which normally follows an ordinary good night's rest after a number of previous nights have been sacrificed.

In the following cases the dose was in each instance fifteen grains—unless otherwise specified and was always given at bedtime.

Mrs. O., aged forty-two, since her husband's death some weeks before, had lost her appetite and suffered from globus and sleeplessness. There was no cardiac murmur but the first sound was decidedly weak. In this case, as in several others, the dizziness alluded to, occured. She slept well after each dose.

Mrs. S., aged twenty-nine, who had had an ovariatomy performed a year ago and eight weeks since another gynecological operation of which I did not learn the nature, was dominated by some imperative ideas which caused her to dread going alone into the front room of her house, and to tremble with fear at the sight of a funeral procession. She had a tender abdomen, obstinate constipation, and slept only two or three hours in a night. A few nightly doses with the use of cod liver oil and tonics and proper attention to the bowels, started her at once on the road to improvement.

Mrs. R., widow, aged forty, with three noisy and ill-behaved children, suffering with a neuritis the result of a fall, gained the rest which had long failed her with the first dose.

Mrs.——, aged sixty-three, widow, had an aortic murmur, dilatation of the stomach, some pulmonary œdema, and partial suppression of urine. Sleep had been poor for weeks but came promptly with the use of Trional.

Mrs. McK., aged twenty-three, had slept poorly during the last weeks of her gestation and continued to do so after labor. The first dose failed but the second, on the following night, succeeded.

Mrs. L., widow, aged forty-seven, with cardiac hypertrophy, chronic pericarditis, loud mitral murmur, bed-ridden for several months, slept well on Trional. Bromides, stimulants, and antispasmodics had been used before with indifferent success. Trional was administered only every other night. After some three or four doses had been used in this way, she experienced a severe attack of cardiac depression (she had before had a number of milder attacks.) Trional, however, had not been taken on the night immediately previous to this attack, but the possible influence of it as a causative factor would nevertheless seem to point to caution in its administration in a case of so extensive heart lesion.

Mrs. E., aged thirty-two, always a poor sleeper, was suffering from very violent headache, which had been preceded by an acute coryza and was accompanied by neuralgic pains in the sciatic nerve, from which she often suffered. She took during the night Trional, and during the day:

Potass bromid.....	ʒ iij
Tr. cannab ind.....	f. ʒ iij
Rxt. ergot. fid.....	f. ʒ ij
Syr. acac.....	f. ʒ ij
Aquae, q.s. ad.....	f. ʒ vj

M. Sig. One tablespoonful every three hours.

She was completely relieved in forty-eight hours.

Miss E. F., aged forty-seven, had been for some months under treatment for vague nervous symptoms, including a girdle sensation and various paræsthesias of the lower limbs. Her sleep was poor. She described the feeling just prior to going to sleep as "very queer." and was drowsy all next day.

Miss A., aged forty, a neurasthenic with frequent neuralgic and migrainous attacks, had some wheals of urticaria which she feared would result in another severe attack such as she had a year previous and which had proved extremely rebellious to treatment. She took Trional for two nights in succession, with three grains sodii salicylas, three times a day, and promptly aborted the attack.

J. C., male, aged thirty-two, in an advanced stage of pulmonary tuberculosis with a neuritic palsy of the serratus magnus muscle, had just passed through several slight hemorrhages. He slept very soundly under use of Trional, but was very drowsy all next day.

Miss D., aged twenty-three, always a poor sleeper, was suffering from the depression of influenza. She slept soundly on Trional.

G. S., male, aged forty, was in the period of delirium and hallucinations of sight of his first attack of delirium tremens. He was extremely tremulous and his urine was loaded with albumen. His appetite had been very poor for months before the attack, which resulted from steady hard drinking rather than from occasional debauches. His sleep too had been extremely poor. The Trional failed entirely, though repeated within an hour, and later in the night one-quarter grain of morphia was used hypodermically and succeeded in producing sleep. A few nights later, when the delirium had almost entirely subsided but the sleep had not yet become established, twenty grains of Trional succeeded admirably and no further medication was required in this direction.

Mrs. D., aged thirty-nine, of an hysterical diathesis and suffering great nervousness and depression from anxiety about a very sick daughter, slept fairly well on taking fifteen grains of Trional.

Trional was also given in a variety of conditions in smaller doses with a view of ascertaining what other properties besides those of an hypnotic, it might possess.

In a number of the milder cases of la grippe that presented, where the main symptoms were a decided nasal and pharyngeal catarrh, doses of one to three grains every two or three hours when used alone, seemed to speedily dissipate the symptoms, but when combined as in the following formula, acted still more efficiently especially in such cases as had subsided into a subacute form, or where a chronic catarrhal affection had been exaggerated by the epidemic influenza.

Quin. Sulphat.....
Trional.....
Salol.....
Camphora..... } āā gr.x.

M. et. in capsul. no. X div.
Sig. One capsule four times a day.

It will be seen that the quinine and salol were given in too small a dose to have much efficacy alone; while it must be admitted that camphor is usually a very excellent medicament in the more acute cases of this kind in the dose used. I am, however, inclined to think that the combination is more useful than is any one of the drugs singly, and this too with a full experience in the use of the older ones.

In a case of severe chorea, which the mother said had existed since infancy the boy being seven years of age, quite remarkable results were achieved by the administration of four grains t.i.d., for two weeks. Fowler's solution had been tried for the same length of time without any appreciable result. The patient being a dispensary case, has not returned, so that the further result remains in doubt. In another case of chorea, a girl of four, three grains, four times a day, failed utterly to do good.

A woman of sixty, with a heart murmur, had also been for some months afflicted with a brachial neuritis, which periodically became intensely painful and required occasionally the use of opiates. She was very promptly relieved in her last attack, and apparently more permanently than previously by:

Quin. sulph..... grs xx
Trional..... grs xxx
M. in caps. no x div. Sig. One every three hours.

It should be stated that quinine, phenacetine, acetanilid, salol, and other analgesics, had been freely used in former attacks.

I think myself fully warranted in coming to these conclusions:

1. That Trional deserves a high rank amongst hypnotics.
2. That it has a useful range of application in catarrhal inflammations.
3. That it deserves trial in neuralgic and myalgic affections.
4 That it may be found useful in chorea and other neuroses.

DIFFERENTIAL DIAGNOSIS OF ROTHELN, ROSEOLA, MEASLES, AND SCARLATINA.*

H. J. WARMUTH. M.D., SMYRNA, TENN.

Nothing in the whole domain of pædiatrics has produced so much perplexity or worry to the mind of the medical man, as the difficulty often experienced in forming a correct and satisfactory diagnosis between rötheln and the other eruptive fevers in question; not so much on account of the treatment, which in either case cannot be of any possible harm to the patient, but on account of a forced and needless isolation, which necessarily must entail loss of time and money upon the parents of the patient or upon the patients themselves.

Rötheln has been frequently mistaken for roseola, and various writers have given a very correct description of the latter under the false synonyms of "Rose-rash" and "Roseola epidemica." When we consider the fact that roseola is a non-contagious dermatitis while rötheln belongs to the class of eruptive fevers which are more or less contagious, we cannot understand how some writers can advance the theory that roseola will, under certain conditions, assume an epidemic character, become contagious, and acquire the power of self-propagation.

Rötheln—rubeola, or "German measles," or "false measles,"—has been known and accurately described in the United States as far back as 1845. This malady seems to have its appearance first in Boston, then in New York, and from that city it has spread all over the country.

It is a hybrid, an intermediate between measles and scarlatina, and yet distinct from either in that it does not confer immunity against either of these diseases. In some epidemics it partakes of the character of measles, while in others it resembles scarlet fever, and in yet other instances it stimulates both, rendering a diagnosis extremely difficult.

In very mild cases the prodromata are wanting, or so mild as scarcely to attract attention. In some epidemics, however, nausea and vomiting, slight catarrh, sore throat, and especially an enlargement of the glands of the neck back of the sterno-cleido-mastoideus, which is characteristic of rötheln, form the initial symptoms. In from six to twelve hours, with an increase of fever (which scarcely ever exceeds 101° or 102° F), a rash appears upon the forehead, around the ears and along the neck, and, traveling downwards, soon spreads over the rest of the body.

The eruption is characterized by numerous small points thickly set, or circular spots or blotches, of a color intermediate between the scarlet of scarlatina and the dusky red of measles, while between the borders of the rash the skin presents a normal appearance. In exceptional instances the intervening spaces assume an erythematous redness, resembling the efflorescence of scarlet fever. With the exception of the scalp, the plantar and palmar surfaces, the exanthem will appear upon any part of the body and is always accompanied by incessant itching. The rash disappears by the fourth day; in warm weather it remains longer. When mild or idiopathic, it leaves a brown spot; when simulating measles, desquamation is followed by a branny exfoliation of the epidermis; and in the scarlet fever variety, desquamation consists of small scales but never of shreds or flakes.

The attack terminates within a week and complete recovery takes place within twelve or fourteen days. Complications are not frequently met with. As a rule there are no sequelæ, although I, Lewis Smith and other writers, mention chronic bronchitis, enlargement of submaxillary glands, albuminuria, and dropsy.

From roseola it can best be distinguished by the simultaneous appearance of fever and rash in this affection; the absence of catarrhal symptoms and of glandular enlargement.

The diagnosis of rötheln from measles or scarlatina for the first two or three days

* Read before the Tennessee State Medical Society, April, 1895.

is often difficult, sometimes impossible. The croupy cough appearing three days before the rash, the severe catarrhal symptoms, the very red conjunctiva with marked photophobia, are characteristic of measles. The short duration of prodromic symptoms, the shivering, the excessive headache, and especially the vomiting and sore throat before the appearance of the eruption, distinguish scarlatina from rötheln, whose premonitory symptoms are either very mild or wanting.

The temperature in measles ranges as high as 104° F, with an accelerated pulse, which is in proportion to the temperature; in scarlatina it reaches sometimes 106°

DIFFERENTIAL DIAGNOSIS.

	RÖTHELN.	ROSEOLA.	MEASLES.	SCARLATINA.
Prodromata.	Wanting or very mild. Sometimes slight catarrh; sore throat; enlarged glands; nausea and vomiting.	None. Rash and fever appear simultaneously.	Malaise; severe catarrh; watery eyes; photophobia.	Shivering; headache; hot skin; vomiting; sore throat.
Period of incubation.	9-21 days.	None.	10-14 days.	4-10 days.
Occurrence of eruption.	6-12 hours.	Fever and rash appear together.	3-4 days from onset of fever.	2-3 days from fever.
Character of eruption.	Small, dark, rose-colored points, sometimes like measles, but lighter; at other times like scarlatina; with normal skin between margins. Appears first behind the ears, forehead, face, etc, and travels downward.	Small rose-colored papules slightly elevated. Scattered over chest, neck, face, abdomen, and sometimes over the rest of the body.	Papular in character, like flea-bites. Of brick red color. First on forehead, ears, face and gradually extending over the whole body.	Bright scarlet dots, which coalesce without leaving normal skin between borders. First on chest, neck and face, and gradually invading the rest of the body.
Pulse and temperature.	In proportion to temperature, which ranges from 100-102 degrees.	Quickened. Normal; seldom 102 degrees.	Quick, but bears a ratio to temperature, which ranges from 101-104 degrees.	Very fast, and out of proportion to the temperature, which often reaches 105-106 degrees.
Eyes.	Pinkish red.	Not affected.	Red, watery. Photophobia.	Very red
Tongue.	Furred.	Slightly furred.	Furred, but not coated.	Strawberry tongue.
Fauces.	Red.	Little injected.	Dark-red and swollen.	Dusky-red. Very much swollen.
Condition of bowels.	Normal.	Normal.	Diarrhœa.	Normal; occasionally constipation.
Kidneys.	Rarely affected.	Not affected.	Not affected.	Nephritis and albuminuria frequent.
Glands.	Affected from beginning.	Not affected.	Bronchial glands always enlarged.	Enlargement after a few days of fever.
Desquamation.	Brown spot; when like measles it consists of a branny exfoliation, and when simulating scarlatina it consists of small scales.	Leaves a distinct discoloration; seldom followed by desquamation.	Furfuraceous exfoliation of epidermis.	Peels off in flakes or shreds.
Contagiousness and Duration of same.	Feebly contagious. 10-14 days.	Not at all. 24 hrs.-3 days	Contagious and infectious. 14-21 days.	Very contagious and infectious, and Lasts as long as desquamation, and longer.
Sequelæ.	None.	None.	Ophthalmia. Affection of organs of respiration, Diarrhœa.	Nephritis, endocarditis, suppuration of glands, etc.
Termination.	Recovery.	Recovery.	Recovery, but sometimes followed by bad health.	Recovery; frequently retarded by sequelæ.

F, with a pulse greatly quickened but out of proportion to the height of the fever; in rötheln the temperature rarely reaches 101° or 102° F, and the pulse bears a ratio to the temperature.

In measles the bronchial glands are enlarged; in scarlatina an enlargement of the glands of the neck takes place after the first few days of fever; and in rötheln it is present from the very beginning of the attack, especially back of the sterno-cleido-mastoideus.

The eruption in measles is more of a brick-red color, papular in character, like flea-bites, and appears on the third or fourth day of the fever. In scarlatina the skin is swollen and unusually hot to the touch; the rash consists of small points of a bright scarlet color, more intense at the center and gradually fading from center to circumference; it becomes confluent by its borders, without leaving any skin of normal appearance between, and appears on the second day of fever. In rötheln the dark-red, rose-colored points may coalesce into patches, but the skin between the margins presents a normal appearance.

In measles and in rötheln the tongue is slightly furred, but in scarlatina we find the characteristic strawberry-tongue which is formed by the projection of the enlarged red papillæ through a thick, white fur.

The fauces in measles are very red and swollen; in scarlet fever they are dark-red, very much swollen and frequently covered with a white tenacious mucus, and this throat affection is always in proportion to the eruption; but in rötheln, though the fauces are red and slightly swollen, they are dry.

While diarrhœa is characteristic of measles, the kidneys are not affected; in scarlatina there is no diarrhœa, but albuminuria and dropsy; and in rötheln the bowels are not disturbed, but the kidneys may become, though rarely, slightly affected.

In measles desquamation begins on the seventh day of fever and consists of a furfuraceous exfoliation of the epidermis; in scarlet fever a peeling of the scarf skin in large flakes or shreds begins on the fifth day; and in rötheln desquamation consists of small bran-like scales.

Measles and scarlatina are both contagious and infectious, while rötheln is feebly contagious.

The duration of infectiousness in measles lasts from fourteen to twenty-one days; in scarlatina as long as desquamation lasts and even longer; and in rötheln from ten to fourteen days.

The sequalæ in measles are ophthalmia, chronic diarrhœa, and various affections of the organs of respirations; in scarlet fever, otitis, nephritic troubles, endocarditis and suppuration of glands; and in rötheln practically there are none.

The termination of all three exanthematous fevers is towards recovery, and only in severe cases of measles and scarlatina does death intervene, or an attack is followed by bad health.

Typhoid Fever in Infants.

1. Typhoid fever occurs more frequently in children than is generally supposed.
2. The fact that ulceration and hemorrhage is much less frequent would explain the absence of pronounced abdominal symptoms.
3. The erratic, undeveloped and hypersensitive nerve centers in early child life explain why the toxic secretions of the Eberth bacillus should make cerebral symptoms very pronounced.
4 Given a child of any age with or without intestinal disturbance, with a continued elevated temperature, with or without marked evidence of cerebral disturbance, the possibility of the presence of the Eberth bacillus of typhoid fever should be constantly kept in mind.—*Journ. Am. Med. Assoc.*

Bacteriological Examination of the Vaginal Secretion During Pregnancy.

With a view to determine the presence or absence of germs in the genital tract of the pregnant patient, where no possibility existed of contagion, Krong (*Deutsch. Med. Woch.*) has made a series of examinations in the Leipzig clinic. He had forty-eight cases, and his results show that the natural resisting power of the tissues is the same to both spores and cocci. Sreptococci were killed in a very short time. Two days is the longest time in which germs introduced within the body remained alive. The genital tract is aseptic in healthy women when from forty to seventy-two hours have elapsed since the last examination.—*Am. J. M. Sci.*

DIFFERENTIAL DIAGNOSIS OF THE ERUPTIVE FEVERS, WITH SOME OBSERVATIONS ON EPIDEMIC AND ENDEMIC INFLUENCE IN THEIR PREVALENCE.*

J. S. NOWLIN, M.D., SHELBYVILLE, TENN.

They are similar in that each has a period of incubation, a period for the fever, and other symptoms prior to the eruption, and a time for the eruption and decline.

Variola or small-pox is the most virulent of the contagious diseases when the people are not protected by vaccination. I believe that vaccination of the greater number, together with modern sanitation, modifies it greatly among those who have not been vaccinated. The incubation is from seven to twelve days but has been known to reach twenty. Intense frontal headache, intense lumbar pains, and aching limbs are peculiar to small-pox. They are more excruciating in this than any of the eruptive fevers. Frequently there is persistent vomiting. On the first day the temperature rises rapidly to 104° or 105° F. The face is flushed; the eyes bright and clear. There may, or may not be delirium, which is dependent on temperament and brain sympathy. Convulsions are not uncommon with children. In a few cases, on second or third day, certain rashes appear which are well calculated to lead the attendant astray as to measles or scarlatina. The throat is oftentimes quite sore. Cough may be present, but is not a prominent symptom.

The eruption appears from the third to fourth day of the initial fever. It is a red spot with a shot-like feeling. It shows first on the forehead near the hair, and also on the wrists. Within twenty-four to thirty-six hours it may be seen on the chest and limbs. The red spot develops into a vesicle, which soon becomes umbilicated and ends in a pustule.

As the eruption comes out the fever cools and the pulse and temperature become normal for one or two days, but when the papules vesicate, the fever rises the second time.

Rubeola or measles also has an incubation of ten or twelve days. Fever runs four to five days before the eruption appears. It is not so high as in small-pox. It does not cool with the eruption, but continues until convalescence. Patient feels chilly, has head-ache, back-ache and pain in limbs, not so severe, however, as in small-pox. There is sneezing, cough, free nasal discharge and copious lachrymation. Conjunctiva red, some redness in throat, huskiness of voice, and soreness in chest.

The rash appears on the cheek or forehead about the fourth day, sometimes later. It is a small red papule which may coalesce with others. The cuticle of the face is thickened. The eruption passes from the face to the body, thence to the limbs, occupying three or four days; disappearing on the face as it comes out on the feet.

Let us compare the semiology of small-pox and measles.

SMALL-POX.	MEASLES.
Fever cools on eruption and returns again.	Fever never cools until convalescence.
Eyes clear and bright.	Eyes red, suffused and watery.
Excruciating pain in head, back and limbs.	Pains not so severe.
The mucusa of eyes, throat and lungs not much involved.	Mucosa of eyes, throat and chest all catarrhal.
Papules shot-like; change to vesicles and then pustules.	Papules only thickening of the skin, no vesicle, no pustule.

In scarlatina the incubation is variable from three to ten days. Peculiar to childhood under ten years, though adults may have it. No special marked symptoms or prodromata.

The throat usually has a scarlet blush before the eruption, and the papillæ stand out prominently as red points dotted over a white coated tongue.

The fever does not precede the eruption more than two days, and frequently only one. It is intense, reaching a temperature of 104 or 105 degrees, with a pulse-rate of 120 to 150. The fact that it attacks children, the throat complication without catarrhal symptoms, together with the rash, which is a scarlet blush developed from little red points apparently under

*Read before the Tennessee State Medical Society, April, 1895.

the skin, reminding one of goose-flesh, and the paling of surface on gentle pressure with the finger, gradually returning from the outer margin to the center when the finger is removed, are sufficiently characteristic to differentiate it from the other exanthemata.

Varicella or chicken pox, is a disease of child-hood but grown people have it. It is not a dangerous disease and becomes important only from its similarity to small-pox. It has an incubation of ten or twelve days; fever only twenty-four hours, when slight papules form on chest and may then appear on different parts of the body. After three or four days these dry into a small black scab without pustulation, or umbilication as in small-pox.

Rubeola, or rötheln, has many marked similarities to measles, and it is even now a question with many as to whether it is entitled to a distinct name. Some competent observers believe that it is a hybrid of measles or scarlatina.

The stage of incubation is placed by different observers at from five days to three weeks. The eruption frequently appears without premonition. It differs from the ordinary type of measles by beginning on the face and spreading rapidly over the whole body. Patterson claims that it makes its appearance simultaneously over the whole surface. The eruption is sometimes scant. Griffith saw it in circular bands above the knee. It disappears in twenty-four to thirty-six hours.

It differs from scarlatina and measles in the light character of the fever. The sore throat and facial catarrh are always present, but very mild. It differs from measles in the involvement of the lymphatic glands. The cervical, occipital, submaxillary and sublingual glands are affected in more than fifty per cent. of the cases. Sometimes the axillary and inguinal glands are swollen.

The light rose color of the eruption, its early disappearance in from one to two days, and the more extensive affection of the glandular system, with the fact that the symptoms gradually subside from the appearance of the eruption, distinguishes it from scarlet fever.

I notice that these diseases now and then prevail as epidemics. This is not only true with regard to the exanthemata by which one attack renders the subject immune for life, but it is also true of cholera and la grippe, the two latter not bringing immunity from a second attack. I notice further that there is oftentimes an interim of five to ten years in which the people seem to be immune from any given one of these diseases. I claim that the great mass of the people are immune for the period of this interregnum, because I take it as an accepted fact that they do not originate *de novo*, let the cause be what it may.

I have observed further, that when one of these epidemic diseases has had its day, it is rapidly succeeded by each of the others until all have passed in review.

It is also a fact that when one of these maladies is prevailing, whether as an endemic (which I think is now accepted to mean only a more limited number of cases or to compass a smaller territory), or whether as an epidemic, the others all subside. That is to say the prevalence of one of these diseases renders immunity, for the time, from the others.

I know that cases have been seen, where two diseases were incubating in the same person, at the same time, and that the one became latent until the first had its course, and then became active. This seems only to prove that the causes of the two could not coalesce, but that both retained their identity and the more potent one ran its course first, holding the weaker in abeyance for the time being.

This does not disprove my proposition that there is such a factor as an epidemic influence which becomes wide-spread and prevails over states, continents and hemispheres at the same time.

Such were the facts two years ago, when small-pox prevailed as an epidemic in thirteen of the States of this Union, and at the same time was in England, France and Russia. Just preceding that, la grippe was gripping the people all over the United States and Europe. Since that time, as small-pox is yielding the field, scarlet fever is frightening the mothers of this country.

It cannot become so extensive because its class of subjects is limited by age.

One of the theories for natural immunity is the phagocytic, as set forth by Metchnikoff. It has been claimed to have a wider applicability than any other solution of this question.

The phagocyte is a white corpuscle which has the power of absorbing and

destroying bacteria. When the system would be infected with the particular bacillus or micro-organism having the power to produce one of these specific diseases, the amocloid cells, or white cells, absorb and destroy them either by digestion or a chemical process in the interior of the cell or corpuscle. Thus the leucocytes or white corpuscles of the blood, become, according to this theory, the defenders of the body against the myriads of bacteria..

We have also the humoral theories of immunity, which attribute germicidal force to the blood and fluids of the body.

Nuttall demonstrated the power of the blood to destroy bacteria. It seems to be established that the greater germicidal power of these fluids is in the serum of the blood. It is further claimed that this bower is stronger in the serum of some animals than of others. Upon these supposed facts the blood serum therapy is now being tried. Without accepting or rejecting, I will say that I have no doubt much good will be developed from these investigations.

While it may or may not be true that the microbic theory of the etiology of diseases, is correct, I am sure that the cause for these epidemic diseases, whatever it may be, is existing continuously. I think power for resisting these diseases or the susceptibility to them cannot be found within, either in the blood or other vital forces of the body.

There must be certain external influences or environments which render the system susceptible.

This may be illustrated by gathering a regiment of a thousand men from the walks of civil life and putting them into camp. Measles and small-pox will soon appear among them and become epidemic. Not only so, but they will be subject to nearly all the epidemic diseases.

This is an endemic influence begotten of their changed habits and surroundings. While it is true a case now and then will be found among the people outside the encampment, yet it never becomes epidemic outside the camp, or if it should, it would not be from the nidus of the camping ground.

From these observations I conclude that there are long periods of time when the people are immune naturally, from one and all of the zymotic diseases. Also that this natural immunity from one is at the same time an immunity from all; which, if true, may be taken as proof of the unity in kind of the etiology of them all.

DIGITALIS.*

J. NEWTON HUNSBERGER, M.D., SKIPPACK, PA.

If human existence is ever prolonged by the use of a drug—and the question, to say the least, is debatable—digitalis stands at the head of the list. But there is not a therapeutist living who can point out a drug, or a combination of drugs, that can *at all times*, be relied on to fight disease to a successful issue. We have nothing in medicine that we dare pin our faith to, unless we are riding a hobby, and hobby horses notoriously are uncertain animals.

Looking over the whole category of acute diseases, it is absurd to say you can abort any of them by the use of drugs, or that we have any known remedy which acts directly on the exciting cause, whatever that may be. All we can hope to do is to second our patients with bottle and sponge, clear the ring and give nature a fair fight—never forgetting that depressing measures, except in a very few cases, will impose a handicap on our patient that may cause the fight to be lost.

In chronic heart disease, whether affecting the heart muscle itself or the valves, digitalis and rest in the recumbent position are about the only remedies worth mentioning.

A cardiac murmur, whether loud or soft, unaccompanied by any other symptoms of a deranged organism, demands no treatment whatever, unless it be some advice regarding over-exertion or violent exercise. It is only when signs of failing

*Read before the Montgomery County Medical Society, May 1, 1895.

compensation occur that active treatment is needed. I recall vividly when in my early college days as I listened in awe to the learned dissertations of my instructors on little weak, scrawny murmurs, I stood in such fear of abnormal sounds that I could always hear the creaking of the graveyard gates as I auscultated the hearts of the poor unfortunates. It is not the murmur so much as the force of the cardiac impulse which should put us on our guard. To say that digitalis should be used not at all or very carefully in some forms of heart disease, applies to any drug that is capable of affecting the system so powerfully.

But I wish particularly to speak of the use of digitalis in acute disorders—principally diphtheria, typhoid fever and pneumonia. Let us glance at the physiological action of digitalis upon the circulation. The first effect noticed is a decided decrease in the number of heart-beats, due to an increased period of diastole. The systole is increased in force so that the ventricles become pale or white as the blood is squeezed out of them. This complete systole drives out all the venous blood from the heart muscle. The coronary arteries arise at about right angles to the aorta, and as the latter fills during systole the blood passes into the aorta in an unbroken stream, and probably little blood enters the coronary arteries at this time. But when the reflex wave causes the aortiic valves to close, the blood rushes into the coronary arteries with all the force of the increased arterial pressure, filling to their utmost capacity the cardiac arterioles supplying the life-giving oxygen to the hardest worked muscle in the body, feeding the nerve centers existing in the heart, and taking out the carbon di-oxide and debris of combustion.

In disease, the feeble heart is unable to free its walls of venous blood during systole; the systemic arteries are not filled sufficiently to produce a reflex wave strong enough to fill the coronary arteries, and the weakened muscle becomes still weaker from starvation. More than this, the lack of properly oxygenized blood to the muscle-wall tends to paralyze the peripheral inhibitory centers and allows the accelerator fibres of the sympathetic to drive the heart to its death.

I quote H. C. Wood: "Digitalis in moderate doses stimulates the musculomotor portion of the heart, probably its contained ganglia, increases the activity of the inhibitory apparatus and causes contraction of the arterioles, probably by an action on the vaso-motor centers in the cord, and also upon the walls of the arterioles.

"In consequence of the first action the cardiac beat becomes much stronger, as the result there is narrowing of the blood paths, and to the passage of the vital fluid an increased resistance, which acting on the already excited inhibitory system tends to slow the pulse."

I might also speak of digitalis as a mild antipyretic, and I am convinced that it has such an action even though it is feeble. But antipyretic drugs should have no place in the treatment of acute disorders. What can not be accomplished by the use of external cold cannot be safely accomplished by internal medication.

I suppose it would be considered rank heresy to leave out antitoxine in considering the treatment of diphtheria. And yet it savors strongly of quackery to imagine that a dram or two of serum in one or two thousand times that amount of blood will effect a cure. Before the Ides of March of another year shall come and go, the immunized horses of to-day will be relegated to the garbage carts.

A large percentage of the deaths from diphtheria are due to paralysis of the heart; heart-clot the result of cardiac failure; pulmonary congestion, the result of a weakened heart; and pneumonia. All are conditions indicating the use of digitalis. The heart beats may be excessively slow, as in paralysis, extremely rapid, or intermittent.

In all of these conditions, cardiac stimulation is demanded. Alcohol is probably of the most service when there is profound shock due to systemic poisoning—strychine, when there are any symptoms of paralysis. But each of these drugs should be combined with digitalis. In the first place it steadies the heart, allows the blood time to become thoroughly oxygenized in the lung, and as oxygen is of the greatest value in all adynamic conditions, the necessity of ridding the blood of its carbon-dioxide is evident. In the second place, the heart increases its own supply of blood through the coronary arteries and thus puts itself in better condition to

fight the coming weakness. And last but not least, it is a stimulant to the pneumogastric nerve. This action undoubtedly has a tendency to prevent the paralyses that so often follow attacks of diphtheria. After vomiting has been controlled, in all except the mildest cases, small doses of digitalis should be given, twice or three times a day. If any indications of cardiac weakness occur or cyanosis comes on, even if due to mechanical obstruction, among other remedies, increase the dose of digitalis. The drug should be continued in small doses until the end of convalescence.

In typhoid fever I have found digitalis of the greatest service, not so much in the first and second weeks, as later in the disease. In the earlier stages of the disease, with a fair ratio between temperature and pulse-rate, the heart acting regularly with a good first sound, stimulants of any kind will do more harm than good. But if the heart is irregular in its action, pulse out of all proportion to temperature, with a weak first sound, than digitalis is indicated. This condition, I believe is due, partly at least, to a poisoning of the inhibitory centers of the brain which allows the accelerator nerve to drive the heart so rapidly. You will often find in this condition a general nervous unrest, twitching of the muscles, of the face and of the limbs, inability to bear noises, and sleeplessness. I have seen digitalis act with the happiest results in such conditions—usually given alone, sometimes combined with the bromides. This quieting action of digitalis is due to an increased blood supply and of a better quality to the nerve centers, and also to a stimulation of the pneumogastric nerve.

We have the same action shown in the quieting effects of the drug when given in large doses in delirium tremens. Later on in the disease, say after the fifteenth day, 75 per cent. of all cases are benefited by digitalis—given probably once, twice or three times in the twenty-four hours. The tincture should always be used, given in from two to twenty drops, as often as indicated. The dose should always be regulated by its action on the heart. If the heart is rebounding strongly against the chest wall, lessen the dose or discontinue the drug entirely for a day or two. Harm may be done by an excessive action. The aim should be to attempt to keep the heart acting in proportion to the action of the rest of the sick body. Do not expect a weak heart in a body emaciated perhaps to the last degree, to act as strongly as in health. But keep up a gentle, stimulating, tonic effect on the heart muscle and inhibitory centers.

You may be assured that you will always have a resultant action from the use of digitalis, and whether that effect does good or harm depends entirely on the skill with which you administer it. It is true that in typhoid fever the heart as well as the muscular system generally, may undergo degeneration changes. But you rarely find a general fatty degeneration of a waxy character in the heart muscle. It is usually granular, affecting small patches alongside of which are healthy fibers that have undergone no degenerative changes whatever. Instead of digitalis being contra-indicated in this condition, it may be of the greatest service. For there is no doubt but that a longer diastole, which means a longer sleep for the tired heart, with its stronger systole and concomitant better blood supply, will tend to lessen the area of fatty degeneration. More than this, the better oxygenated blood circulating throughout the system will improve the general tone of all the organs.

There is, probably, no one disease which has been treated with such a variety of methods as pneumonia. Each method, of course, followed by a large proportion of recoveries. It is, I think, generally recognized at the present time that pneumonia demands no special treatment, but that each case must be treated on the symptoms which it presents.

In a strong, robust man or women, with a hard, rapid pulse, depressant measures, bleeding included, may be of the greatest value. But the great majority of cases the average practitioner sees are the pneumonias of children and not overly robust men and women—often those of low vitality. These are the cases that demand plenty of easily assimilable food, tonics and stimulants, of which digitalis is easily the most important.

It has not been proven that we can prevent the progress of pneumonia by any known method, or hasten a cure by any drug. There is also no doubt but that many *active* measures designed for the relief of the congested lung and to limit the area affected, do but sap the vitality of the patient and handicap nature in her

heroic efforts to heal. We should never forget that the vital elements which constitute life are always, even in health such civilization gives us, struggling for existence. They never pull down, they are ever striving to build up.

The treatment of the second stage of pneumonia is essentially one of stimulation. Digitalis is the drug that meets these indications and meets them more efficiently than any drug or combination of drugs in the pharmacopœia. It tends to prevent overdistention and paralysis of the muscular fibers of the right heart. It empties the ventricles and itself of all its blood by a complete systole; steadies the heart muscle by the action on the heart itself, but mainly by its stimulation of the pneumogastric nerve. This nerve supplies motor fibers to the muscular coats of the entire bronchial system, including lobules and air cells; an important action in equalizing air pressure and preventing overdistention of healthy vesicles.

It must be apparent that digitalis, by its stimulation of this nerve, plays a most important *rôle* in respiration. The vagus also regulates the rhythm, keeping it working regularly. As is shown by section of both pneumogastrics in the neck, which diminishes the number of respirations to four or six a minute, until death finally occurs in five to seven days, we have from digitalis practically the same action on the respiration as on the heart. The breathing becomes fuller, steadier, stronger, the blood becomes more completely oxygenized, and the nerve centers, rallying with their fresh supply of oxygen, again take up the fight.

ETIOLOGY OF DIPHTHERIA.

P. J. FARNSWORTH, A.M., M.D., Clinton, Iowa.

Spontaneous generation has long been disapproved. Bacteriology arose in its place. For a time it was thought that bacilli might be protean in form, and capable of transformation. It is now generally conceded that each reproduces its own kind, and causes its own disease. In some doubtful cases there may be similarity in appearance which has led to mistakes. Cultivation and inoculation tests decide the difference.

In this light, what is the immediate cause of infectious disease? The answer is ready, of course. The introduction and growth of a peculiar bacterium: variola from the germ of variola; scarletina from the infection of scarletina; and diphtheria from the introduction of the Klebs-Loffler bacillus. In the latter disease, as in the Parable of the Sower, many seeds fall by the wayside and are devoured by the phagocytes; others fall on stony ground and do not spring up; a few, unfortunately, fall on ground suitable to produce disaster.

It is not our purpose to describe the progress of the disease, but its beginning. Diphtheria starts in a hamlet or city, and prevails seemingly until the soil is exhausted. It sometimes remains in one locality for several years perchance, invades only certain streets. It finds its way to isolated farm-houses and is confined there, or it may spread to the neighborhood. It does not arise spontaneously in either case, nor does some harmless germ suddenly develop malignancy. The genuine bacillus has been carried there and found a soil in which to propagate.

In many cases, heretofore, it has been impossible to account for its coming; in some instances the manner is patent.

With our present knowledge we may know our enemy and put ourselves on our guard against him. These are facts for our consideration:

"Under favorable circumstances in culture tubes, the bacilli have been found alive *after seven months;* and on bits of membrane kept in cloth, still alive after six months."

Dr. Fischer, of New York, found true diphtheria bacilli in the sinks and traps of houses where diphtheria had prevailed.

In mild cases the bacilli are found in the nasal secretions and in the throat where little disease seems to exist, and after the disease has disappeared, as sup-

posed. This is particularly the case among members of a family that seem to be immune.

These facts cannot be too widely known and acted upon to prevent the spread of the disease. When the disease breaks out do not look for its origin in the sewer or the well—such is only the soil on which it is planted, the seed has come from some other source. It may be carried in clothing and on the person for several months. Disinfectants may be used in the most thorough manner, everything be destroyed that has come in contact with the disease, yet the bacilli may remain in the nostrils or throat, or about the person of those that have had the disease or have been in attendance, and thus be "mysteriously" transported.

It is a noted fact in this city, that as soon as cold weather sets in and winter clothing is taken out, we have cases of scarlet fever. The germs have been packed away in the spring in spite of disinfection, and are ready to spread themselves when unpacked.

Some years ago, we had after cold weather set in, an epidemic of diphtheria. It began at the bottom of one of the highest, dryest streets of the city. The disease went zigzag from one side to the other, missing some houses and striking others with violence, taking one or more wherever it went. It traveled to the bluff, a mile from where it started; forty out of a hundred died. This happened fifteen years ago, when few precautions were taken to prevent its spread. It appeared in only two or three cases off the one street; though the soil would seem to have been better in many other localities. There is only one fact that offered any explanation—it followed the route of a certain milkman.

A more recent outbreak observed was in a farm house a mile from any neighbor. Sanitary surroundings were much better than on the ordinary farm. A sister of the farmer, living in the center of the State, had lost two children with diphtheria; a third child did not have it. Disinfection had been thorough. No clothing, nor anything in the rooms had been saved. A month in another house had elapsed when she came to visit her brother. Here were four children. The little girl of the sister slept with the two older girls of the brother. In less than a week these were attacked with diphtheria and died. The other two children had the disease in a milder form and survived. Every precaution was taken, but in four or five months it appeared in another farmhouse—a relative. It stopped there.

The cause was supposed to have been a foul well!

REDUCTION OF LUXATION OF KNEE JOINT BY FORCIBLE EXTENSION.

A. O. STIMPSON, M.D., THOMPSON, PA.

D. J. S., an intelligent young farmer of this town, while prying up a large stone in the field with a crow-bar, injured his knee so that he could neither straighten it out nor even bear his weight upon it in an attempt to walk. When the accident occurred on May 17th 1886, he, thinking that his leg was broken, was brought to my office by a neighbor's horse and carriage in order to be treated forthe injury.

Learning the history of the accident and noticing that the pain was greatly aggravated on attempting to rotate the bones at the knee joint, I had come to the conclusion that the trouble was caused by a dislocation of one of the loose cartilages of the joint and that this had got pinched between the head of the tibia and the femur. I got my patient seated in an office chair allowing his injured limb to assume as easy a position as possible and then made an examination of the joint. I found it as immovable as if chronically anchylosed; but I soon discovered that a loose cartilage had been pinched and permanently confined between the head of the tibia and the extremity of the femur.

Rotation of the limb and heroic manipu-

lation did not alter the condition of affairs. I now placed his limb (which had continued to remain in a semiflexed condition) on another chair with his heel resting on the edge of it, then by diverting his attention from what I intended to do I suddenly pressed on this knee with my two hands, leaning my whole weight upon them. A loud snap (like a pistol shot) was heard, and subsequently the fellow could walk around the room as well as ever.

I must not, however, omit to mention that there was also a partial dislocation of the tibia forward, hence the rigid condition.

The cause of this peculiar surgical deformity is easily understood when it is known that this man used his leg (twisted around the crowbar) as an aid in his efforts to move the large stone, thereby materially increasing the leverage power.

ACUTE NEPHRITIS IN THE PNEUMONIA OF CHILDREN.

Dr. Popoff reported four cases recently under his care in which acute nephritis occured in the course of pheumonia. The first patient, a girl of twelve years, had previously had pneumonia at the age of four, but there had then been no trace of of albumin in the urine. She was brought to the hospital suffering from fever, cough and a painful point on the side. Her illness had begun eight days previously with vomiting, delirium and fever, and all the physical signs of pneumonia, which ended in crisis on the ninth or tenth day, with profuse perspiration. The urine was examined upon the day following her entrance to the hospital, and found to be scanty, cloudy, and full of albumin. Microscopical examination showed hyaline and hæmatin casts and leucocytes. These disappeared in a few days, but the urine continued to show a heavy precipitate of albumin. There was no œdema nor symptoms of uræmia. The general condition of the appetite remained excellent. Treatment with methylene-blue was without effect.

The second patient was a boy five years of age, without any previous history of disease. He was brought to the hospital for fever, dyspnœa, and generalized œdema, the latter symptom having appeared on the second day of the disease. All the physical signs of pneumonia, with albumin in the urine, were present. At the end of fifteen days the child left the hospital completely cured. The third case, a girl of six years, with pneumonia, passed urine containing blood-cells and hæmatin casts and 1 per cent. of albumin. She died ten hours after her entrance into the hospital, and the post-mortem examination revealed the presence of pleuro-pneumonia, acute epithelial nephritis, and tumefaction of the spleen. The fourth case was that of a boy twelve years old, with pneumonia and urine rich in albumin. Autopsy showed adhesive pleurisy, double pneumonia, hypertrophy of the spleen, and parenchymatous degeneration of the liver and kidneys.

From these four cases Dr. Popoff concludes that nephritis generally appears on the fourth or fifth day of the pneumonia, the most common symptom being bloody and scanty urine. Anuria or uræmia may supervene, but the casts and hæmatins generally disappear rapidly. The duration of the neperitis may vary from eight to seventy days, though the average duration is from fifteen to thirty days.—*La Médecine Moderne.*

The Effects of Chloroform on the Organism, Especially on the Kidneys.

Allessandra (*Il Policlinic*), draws attention to the fact that in most cases the effects of chloroform on the kidneys are practically *nil.* In patients with renal affections, however, this condition of perfect safety cannot be said to exist, and the author urges very strongly the necessity of carefully observing the urinary secretions for one or two days after the administration of chloroform. When renal lesions are actually in existence chloroform should either be avoided, or at least given with the greatest caution, and prolonged or repeated anesthesias inadmissible.

THE MEDICAL AND SURGICAL REPORTER

ISSUED EVERY SATURDAY

Address all communications to P. O. Box 843, Philadelphia, Pa.

HAROLD H. KYNETT, A.M., M.D.
Editor.

RODERIC C. PENFIELD
Publisher.

Editorial Offices, 1026 Arch Street, Philadelphia, Pa.

Entered as second-class matter at Asbury Park, N. J.

TERMS:—Three Dollars a year in advance. Sent four months on trial for $1.00.

REMITTANCES should be made payable to the Publisher only, and should be made by Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We invite contributions of value to the profession, and if published originally in THE REPORTER such will be paid for at liberal rates, or a limited number of copies of THE REPORTER will be supplied, as the author may elect. Hereafter where reprints are desired writers are requested to make a note of that fact on the first page of the MS., but must order reprints directly from the publisher, who will supply the same at cost rates. Contributors should inclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, JUNE 8, 1895.

EDITORIAL.

"ACCIPE HOC."

By the time he has abraded old wooden benches and has been burnished by the process sufficiently to convince Alma Mater of his fitness for a binding "in full sheep," the medical student is generally in a condition, mental and physical, to interpret the formal words conferring his diploma as a benediction on himself and on humanity at large. He feels that he has finished an irksome task and henceforth is to enjoy the fruits of his labors. Moreover he has an hieroglyphic which certifies to all men that he is qualified and has received the Doctorate degree in Medicine. This talismanic parchment bears the seal and superscription of the faculty, and surely must bring him fame and fortune. He is now one of the initiated. Didactic lectures have revealed to him the mysteries of disease; clinical demonstrations have discovered how to recognize and treat it; in fact he has seen for himself how easy and simple to the initiate is the whole subject which to the novitiate was a dark and bloody secret. He is stuffed and fairly suffocating with the latest improved scientific medicine. Modesty alone deters him from expressing the confidence he feels that he is amply qualified to fill any vacancy which might occur in the faculty of medicine.

We welcome the new recruit to our professional ranks and cordially extend our best wishes for the realization of his highest ambition. We do not wish to obtrude any advice, nor do we expect any individual graduate to apply to himself what we have to say; but the public have some rights which must be respected even by the infant doctor, and to the medical graduate in general we address a few hints gleaned from experience.

What you do not know about medicine would fill so many books that we doubt that even the world itself could contain them. What you have heard and read during your college education is a huge mass of undigested and indigestible ma-

terial which contains a few elements of intrinsic value. Dogmatic assertions, windfallen theories, professorial predilections, demonstrators' hobbies, quiz-masters' "pointers," clinicians' vagaries, and lecturers' platitudes have been so intimately mixed with some truths that are really of value, and the conglomerate has been so constantly and recklessly hurled at your devoted head, that only bitter experience can teach you how much that has been learned must be unlearned to bring some degree of order and co-ordination out of the uncorrelated fragments of truth which will remain. The first lesson, the one hardest to accept although the easiest to comprehend, and the lesson which must be mastered before experience will undertake to instruct at all, is the apprehension of the fact that you know—nothing. The sooner this fact is fully realized the better are your chances for achieving the greatness of your ambition. Probably no other one thing has limited the possibilities inherent to a vast number of medical practitioners, more than the failure to grasp this same primary truth, or else to learn it soon enough.

When we say you have so much to unlearn we are not reflecting upon the teachers who instructed you, nor upon the writers of the books you may have read. A physician, great as a teacher, greater as a writer in general literature, but greatest as a man who, understanding his fellow men, could give expression to his sympathy; a man whom the world delighted to honor; Dr. Oliver Wendel Holmes, speaking of the existing methods of medical teaching, said:

"The reason why we teach so much that is not practical and in itself useful, is because we find *that* the easiest way of teaching what *is* practical. If we could in any way eliminate all that would help a man to deal successfully with disease and teach it by itself, so that it should be tenaciously rooted in the memory, as easily summoned when wanted, as fertile in suggestion of related facts, as satisfactory to the peremptory demands of the intelligence as if taught in scientific connections, I think it would be our duty so to teach the momentous truths of medicine, and to regard all useless additions as intrusions on the time which should be otherwise occupied. But we cannot successfully eliminate and teach by itself that which is purely practical. The easiest and surest way of acquiring facts is to learn them in groups, in systems, and systematized knowledge is science. You can very often carry two facts fastened together more easily than one by itself, as a housemaid can carry two pails of water with a hoop more easily than one without it. You can remember a man's face made up of many features, better than you can his nose, or his mouth, or his brow. Scores of proverbs show you that you can remember two lines that rhyme better than one without the jingle."

Neither is your task now accomplished so that you may cease from your labor and enjoy the fruits of your work. You have been emancipated, perhaps, from old lectures and from benches which are coëval, but you have not been emancipated from work. On the contrary, experience will be sure to teach you that what you have thus far regarded as work is in truth recreation compared to the ceaseless toil and unremitting care and labor inevitable to the practice of medicine. You are not leaving school to work as a craftsman in some trade, nor to take part in the traffic of commerce, nor to supervise machinery in shops, but to practical work in the art of all science, most difficult and responsible for its every day application deals with the interests and lives of human beings. You will be subjected to and harassed by the physical strains incident to incomplete knowledge and incapacity to deal with the material side of your profession. In spite of the

utmost and sincerest efforts and the most incessant study of your profession, the realization of your ignorance will grow with your experience. And your soul will be made sick by the revelations of human weakness and iniquity you must receive and bury in silence, and will be wearied by the burdens of responsibility which will be thrust upon you, and which you must bear without comfort from any human source, for you may not violate any confidence reposed in you—the physician.

Truly your labor has just begun. You must sort and re-sort and pick over again from the chips and junk you have accumulated, and therewith build and build better than has yet been done. You will have to secure new materials also. Very much of the old literature of medicine, very many of the dogmas of the old authorities must die out of the memory of the profession—in fact should never have had a place in it.

To become great in the medical profession requires the exercise of the highest intellectual powers, analytical and synthetical; the staunchest moral principles and courage, and indefatigable labor.

Whether or not the words, "Accipe Hoc," introduces to yourself and the world a new blessing or another disaster, will depend entirely upon a factor hitherto ignored, henceforth of the greatest importance—the personal equation.

ABSTRACTS.

ADMINISTRATION OF NITROUS OXIDE PRELIMINARY TO ETHER ANÆSTHESIA.

M. H. Rogers, Physician and Pathologist to the Bristol England Hospital for Sick Children and Women, writes (*Bristol Med-chir. Jour.*)

As long ago as 1876, Clover described how before ether anæsthesia it was advisable to administer nitrous oxide; so that were it not for the neglect of this valuable suggestion, I should feel that an apology was required for bringing up such a hackneyed question. All the unpleasant sensations experienced during the early stages of ether anæsthesia may be avoided by giving a small quantity of nitrous oxide first.

First of all, I wish to express my regret that chloroform is still so largely used, when we have a far safer and an equally satisfactory anesthetic in ether. As far as I can judge, the causes for its almost universal use—certainly in country practice—are, that its administration requires no expensive, more or less complicated apparatus, and that its use is far more economical. But when we bear in mind the not inconsiderable risk attendant on all cases of chlorform anesthesia, I am convinced that its use should be restricted to those cases in which ether for some particular reason, is to be discarded. There must be, in all cases of anesthesia sufficiently profound for surgical operations, a certain amount of risk; but we may always feel when administering ether that when once sufficiently deep narcosis has been produced, timely warning will be given of any dangerous condition; whereas with chloroform, patients not infrequently pass to a more or less dangerous stage with great and unexpected suddenness. Whether or not we hold, with the Hyderabad Commission, that cardiac failure in chloroform anesthesia is only secondary to respiratory failure matters little in comparing the relative safety of ether and chloroform, for there appears to be no serious risk of either when ether is given.

Without wishing to raise the whole question of the choice of anesthetics, the best methods of administering them, and their relative safety or danger, I must say I believe that a large number of the fatalities from anesthetics are due to inexperience, or perhaps primary want of knowledge, on the part of the anesthetist; or want of attention during the operation to the patient's condition. Experience should be gained during the time of student life, and should not, as is the usual custom,

be postponed till the qualifications to practice are obtained. Plenty of opportunities are given at the hospitals attached to medical schools for students to learn how to give anesthetics, but they are much too often neglected for the superior attractions of the operation. Theoretical knowledge of administration, though not so useful, is of no mean value; but few of our medical schools include a course of instruction in anesthetics in their syllabus, and I have never heard of a question on the subject being asked in any examination. The anesthetist should be wholly engaged in giving the anesthetic, and should pay no more attention to the operation and doings of the surgeon than to see that his patient is sufficiently under to render the operation possible without movement or pain.

Now to the point to which I wish specially to call attention. Those who have had the misfortune to have taken ether will know that the inhalation of the vapour is not altogether pleasing. The odor is pungent, and the taste burning and most unpleasant; and it is impossible, even when given by the most skilled hands, to avoid these disagreeable sensations. When, however, nitrous oxide is given in the manner I shall presently mention, all this unpleasantness is lost; further, there is neither struggling nor cough; in fact, the patient passes from the far from unpleasant sensations of nitrous oxide anesthesia to ether narcosis quite insensibly and quietly. I have had nitrous oxide administered to me more than once, and can assure those who have never experienced it that, beyond a peculiar sweet taste and a tendency to take deeper respirations than usual, the sensation is on the whole pleasurable. In administering gas before ether, only sufficient of the former anesthetic is given to render the patient partially insensible—only till the sensation of lightness of the head is induced; and though I am not prepared to say that any anesthesia of the air passages is produced, practical experience teaches that after a few—six or eight—respirations the irritating effect of the ether on the mucous membrane of the respiratory tract is not observed. On the last occasion on which I took nitrous oxide I attempted to count the number of respirations I took before I became insensible, and on recovery found I only remembered taking twelve. No doubt I should have felt the pain of the tooth extraction if it had taken place then; but this shows how soon loss of consciousness comes on.

The apparatus I use is Hewitt's modification of Clover's ether inhaler: others are in use, but I find this answers its purpose well, and I shall continue to use it till one evidently superior is introduced. The gas-bag, previously filled with nitrous oxide, is fitted on to the dome which has been warmed and supplied with ether. All the fittings of the apparatus should be so accurately made that there is no leakage of gas or ether; so that when the gas is turned on no taste of ether vapor is noticed. The valves are so arranged that respiration of air alone is allowed at first, by which the patient gets accustomed to the face-piece and can be induced to breathe properly—a thing often not done at first—and the anesthetist can hear that the valves are working properly. After a few respirations the gas is turned on, and is drawn from the bag to the patient's lungs and expired through the valves. About six respirations in this way are permitted, when the valve arrangement is turned off, so that respirations now pass from and to the bag, and at the same time a small turn is given to the ether dome. In a short time signs of slight nitrous oxide narcosis are noticed, but should not be allowed to proceed too far. There should not be much lividity, but should it become marked, a single breath of air causes it to disappear. Meanwhile the ether has been turned on till now it is nearly at full, and in a short time the patient is ready. The great difficulty to avoid is, allowing the patient to come round between the gas and ether narcosis—a thing very easily done if too much air is admitted. Only experience can teach the anesthetist how much, and when air should be given. Deep nitrous oxide anesthesia is not desired or required. It will be found that two gallons of gas is about the amount required; but each patient has a personal equation both for nitrous oxide and for ether, and the anesthetist has to find it out by careful and cautious observation. I believe by this method of administration after-vomiting is less frequent. But much, too, depends on keeping the patient equably under the anesthetic at the time of the operation. There should be deep anes-

thesia at first, especially if the operation is on a sensitive part, but much lighter anesthesia is sufficient subsequently; but it must be maintained equably, or as equably as is possible.

To those who have no experience of this method, I can confidently recommend it as by far the simplest, both for the patient and the administrator; and if comfort is concerned, I can unhesitatingly say that it is the best yet devised.

SOCIETY REPORTS.

THE MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA. ABSTRACTS OF SOME PAPERS READ.

PRESENT STATUS OF THE SANITARY MOVEMENT FOR THE ADOPTION OF THE INDIVIDUAL COMMUNION CUP.

Dr. H. S. Anders, Philadelphia.

Attention is directed to the established facts and principles of hygiene which underlie the sanitary argument in favor of the abolition of the common and the substitution of the individual communion cup. Ministers and Biblical scholars of broad and progressive views are rapidly recognizing the disease dangers of the ordinary cup as passed to communicants in turn, among any one of whom incipient or hidden communicable disease may contaminate the mouth secretion and thus be passed to many who are innocent and in good health to jeopardize them. The individual communion cup is presented as the only sanitary, reliable, practicable and practical solution of this problem of danger to the public health in a Christian community. There are no valid scriptural, historical or ecclesiastical objections to the change, according to the majority of protestant denominational authorities.

The individual communion cup has been in use with perfect satisfaction and success, sanitary and reverential, for one year, since its use first by the North Baptist Church of Rochester, New York. Twenty churches, including some of the Methodist Episcopal and Presbyterian denominations, in that city have adopted, or voted for the innovation. The congregations number from 500 to 2,000 communicants.

The distribution of communion wine by individual cups is rendered more expeditious and harmonious, and is no less spiritually impressive.

Four churches in Philadelphia have made the change, the Fourth Baptist, the Bethlehem Presbyterian, the Eighteenth Street Methodist Episcopal and the Heidelberg Reformed. The movement is receiving favorable and intelligent, calm and general consideration in numerous churches throughout the land. New York, Pennsylvania, New Hampshire, Massachusetts, Georgia, Virginia, Ohio, Illinois, Missouri, California, have all to my knowledge received the good seeds of the sanitary reform in proper spirit, and the fruitage is becoming evident in large measure.

ADDRESS IN HYGIENE.

Hildegarde H. Longsdorf, M. D., of Carlisle.

The science of hygiene is under a great onward impulse through the discoveries and researches in bacteriology. The theories based upon these researches have seemed to make the health problem an easy one to solve, but in spite of these tangible results the retrospect and outlook are not re-assuring.

Many questions on sanitary lines remain unsettled; there is a growing fear that the race product is on a lower average than formerly, and that the vigor and manhood which constitute the real wealth of the nation is declining.

The causes for this must be looked for in the increase of the "dissolute and effective" classes, and the want of restraint upon their disease-developing power.

Hygiene in its ultimate meaning is *race development*, and from this standpoint it must be considered among the many

humanitarian and sociological questions that perplex the thinker and threaten the integrity of the body politic.

If prevention is the keynote of the medical thought of the day, it is the height of wisdom to pay heed to the sources of moral contamination. Overcrowding in cities, child-labor, unnatural and unremitting toil by the mothers, are some of the most potential of these causes, and they appeal to the hygienist and to the legislator on the basis of race deterioration and loss to the State.

The absolutely dissolute should be isolated and their labor made productive; first, to prevent the transmission of their pernicious qualities; secondly, to relieve the State of the burden of their maintenance in asylums and reformatories.

MENTAL INFLUENCE IN THE TREATMENT OF DISEASE.

Theodore Diller, M.D., of Pittsburg.

The paper was a plea for the study of mental influences which detrimentally or beneficially influence persons. Attention was called to the fact that little or no effort was taken to protect the public from organized movements like faith-healing, christian science, etc., which exert baneful psychical influence over large numbers.

Physicians can do much to correct evils arising from the influences of christian science, etc., by studying and recognizing the kernel of truth contained in each, using it, and showing, when necessity arises, the evil which proceeds from the ignorant and unauthorized use.

The quack and charletan effect many of their so-called "cures" by first creating or greatly magnifying in the minds of their victims the disease they essay to cure.

In each individual case of any kind, it should be the effort of the physician to remove all baneful mental influences which may surround the patient and create about him a healthful mental atmosphere. Intelligent and kindly consideration, with confident suggestions within careful limits, can generally do all that hypnotic sleep can do, and without the suspicion and mysticism which attaches to the latter.

Above all it is essential to him who uses these mental influences for therapeutic purposes, to be honorable and to possess in himself a character from which shall radiate healthful mental suggestions.

NECESSITY FOR THE ADVERTISEMENT AND ISOLATION OF CERTAIN CONTAGIOUS AND INFECTIOUS DISEASES.

F. LeMoyne, M. D., of Pittsburg.

The object of this paper was to call attention to the importance of advertising and isolating cases of contagious and infectious diseases, particularly of scarlatina and diphtheria. Such affections are conspicuous causes of suffering and mortality, and by proper precautions they are to a great extent preventable.

Existing laws in this State commit the strange inconsistency of exacting precautions and enforcing restrictions in regard to small-pox, which is to a great extent under control by vaccination, while scarlatina and diphtheria, to which a much larger proportion of the population are susceptible, have every opportunity for dissemination and are not subject to proper legal regulations.

The members of the medical profession are the natural and acknowledged guardians of the health of the people and it is incumbent upon them to lead the public mind safely in that direction by emphasizing the fact that every case of scarlatina or diphtheria not carefully isolated and plainly placarded is a shameful menace to the surrounding population.

REPORT OF A SERIES OF CASES OF LARYNGEAL DIPHTHERIA TREATED BY ANTITOXIN, WITH AND WITHOUT INTUBATION.

Edwin Rosenthal, M.D., of Philadelphia.

After brief mention of the historical discoveries in bacteriology leading to the latest method of treatment, he gave a summary of his work. He divided the cases into two groups; one upon whom the operation of intubation was performed, and the other where the operation was not a necessity.

Those cases, ten in number, treated without intubation recovered.

Of those cases, twelve in number, treated with intubation, two died and ten re-

covered; a mortality of sixteen per cent. Combined statistics, before the advent of antitoxin, in cases treated by intubation showed a mortality of seventy-two per cent.—that is twenty-eight recoveries in a hundred. Dr. Rosenthal's own statistics, in a former paper, showed a mortality of sixty-two per cent.—38 recoveries in a hundred. In juxtaposition to this the combined statistics of antitoxin treatment have shown a marvelous reduction in the death rates.

Dr. Rosenthal's work was done mostly with Behring's antitoxin, though he has used Aronson's, Gibier's and McFarland's antitoxin. Almost all his cases recovering, makes their value equal; the German antitoxin, however, brought quicker reaction than the domestic, and for that reason was superior.

Dr. Rosenthal's conclusions are:—Antitoxin is a specific in diphtheria. In early cases, those seen in one or two days after injection, no death rate should be recorded.

In laryngeal diphtheria, the so-called membranous croup, antitoxin is especially indicated. It should be used in every stage or at any date of the disease no matter how late we see the case; its influence can be proven, for cases of laryngeal diphtheria perish from suffocation long before any toxic symptoms could be manifested; for that reason he strongly urges the necessity of prompt intubation when indicated, even if before the injection of the antitoxin. Regarding the use of antitoxin:—Do not delay or hesitate in this disease because the case is not so bad, or because it might get well without it; but use it at once—the earlier its use the more certain its success.

RATIONAL TREATMENT OF FRACTURE OF THE FEMUR NEAR THE HIP-JOINT IN AGED PERSONS

E. V. Swing, M.D., Coatesville, Pa.

The paper recites briefly the history of eighteen cases of what is commonly called "intra-capsular" fracture of femur, and advocates, in all cases of fracture near the hip-joint, in aged persons (seventy and upwards), rest in bed on a good mattress without extension or counter-extension, as giving the best promise of *life* and the most *comfort* while living.

A CLINICAL CONTRIBUTION TO THE STUDY OF THE RELATION OF CONVERGENCE TO ACCOMMODATION.

Howard F. Hansell, M.D., of Philadelphia.

Read by title.

Report of a case of divergent strabismus of many years standing in which binocular fixation was possible only at the expense of clearness of distant vision. Each eye was nearly emmetropic and had no organic defect, and either could be used in fixation. There was no assignable cause for the anomaly.

The interest in the case lies in the transient power of binocular fixation accomplished only by conscious effort and with the simultaneous contraction of the ciliary muscle by which myopia of 3.5 D. was invariably acquired to disappear immediately when the divergence of the optic axes was restored. The association of the function of accommodation with that of convergence where the primary stimulus is directed to the interni instead of to the ciliary muscle, is thus demonstrated, just as reversely normal contraction of the accommodation induces normal convergence, and pathological contraction pathological convergence; instances of which are exceedingly common and indisputable.

RECENT EXPERIENCE IN THE ELECTRICAL TREATMENT OF FIBROID TUMORS AND CATARRHAL AFFECTIONS OF THE UTERINE TRACT.

G. Betton Massey, M.D., of Philadelphia.

In the treatment of two classes of fibroid tumors there is no conflict between the claims of electricity and the knife. There are cases in which electricity in expert hands can give a hundred per cent. of practical cures; not necessarily cosmetic cures, but completely satisfactory in the comfort and well-being of the patient. There are also cases in which electricity can only do harm, and in which ablative surgery is not only wise but imperative.

In a third class true conflict occurs, and I may specify this class as made up of large tumors causing much deformity, and which by reason of their situation or constitution require prolonged efforts for electrical absorption. If the deformity is great it becomes a question for the patient

to decide whether the dangers of an operation should not be faced. Operations are too frequently performed on small tumors in which a complete and permanent cure can be assured from the electrical treatment. Hemorrhagic tumors of all sizes should be placed under this treatment; the author claims never to have had a failure in curing the hemorrhage and pain and in reducing the size. Of non-hemorrhagic large tumors reduction or disappearance is most certain in instances of symmetrically developed interstitial growths.

The class in which electricity is not indicated embraces degenerating tumors in which malignancy may be suspected, and all tumors associated with purulent inflammations of the appendages.

One of the most important services of electro-therapeutics to gynecology is the prevention and cure of tubo-ovarian disease. This affection is dependent upon a uterine catarrh; hence the cure of an endometritis is in many cases the prevention of the former. The positive pole is indicated within the uterus and the negative pole within the vagina at different applications. A large number of young girls have thus been restored to full womanly health, in spite of the fact that some of them had been advised to submit to an unsexing operation.

THE TENNESSEE STATE MEDICAL SOCIETY.

April, 1895.

Dr. J. H. Warmuth, M.D., Smyrna, read a paper entitled

DIFFERENTIAL DIAGNOSIS BETWEEN ROSEOLA, MEASLES, ROTHELN AND SCARLET FEVER.

(See page 803.)

J. S. Nowlin, M.D., Shelbyville, read a paper entitled

DIFFERENTIAL DIAGNOSIS IN THE ERUPTIVE FEVERS, AND SOME THOUGHTS ON ENDEMIC AND EPIDEMIC INFLUENCE.

(See page 806.)

DISCUSSION.

DR. N. G. TUCKER, Nashville: In these exanthematous affections we should exercise great care in making a diagnosis. My experience in the last three years, as Health Officer of Nashville, has led me to believe our physicians are exceedingly careless in this respect. No doubt there is great similarity in these affections, but they have a natural history, which, if properly studied and properly understood, and if we took the care we should take in making a diagnosis, would prevent so many mistakes in diagnosis and treatment. I may mention a case in point. Only a few years ago, a case of small-pox occurred in Hot Springs, Arkansas. A diagnosis was not made until the patient was dead, transported across the country, and other cases developed from it. I believe it is claimed about 175 cases have occurred in Hot Springs, and there are probably twenty-five or thirty localities in this country of ours affected by the disease. It has come into our own State. Several cases have occurred in Covington. If proper care had been used in the first case, it might have been controlled at once. No doubt some of these cases have been pronounced rötheln or German measles. It is true that we have not been entirely clear of it here in ten years. I don't know how many years before that since there was a time when the city was free from it. It has not prevailed the entire year, but sometime during the year a case would pop up. A case called rötheln, chicken pox, or something of that kind, would prove to be a case of scarlet fever. And I will say to the profession and to the people of Nashville, so long as this is true the disease will simply have to wear itself out; it will continue from day to day for the Lord knows how long. Physicians should study these infections. They have their periods of incubation and their periods of eruption; everything is as marked as a crop of corn or of oats, and if you give

more attention, there will be less trouble in the care of these cases.

DR. J. M. COYLE, Nashville: How would you make your diagnosis of scarlte fever in the negro before desquamation?

DR. TUCKER: The eruption will occur in twenty-four hours from the beginning of the attack; in measles, seventy-two hours; and in small-pox seventy-two hours. Among the negroes, where it rarely occurs, the rash appears in twenty-four hours.

DR. COYLE: In the negro the eruption often cannot be discovered. They are not white; they are black, yellow; they are all colors. In the black race scarlet fever may occur and the eruption not be discovered because it may not show itself plain enough for us to see it. We may guess at it but I don't see how we can arrive at a positive diagnosis. And it is from this source the great number of cases are carried to Nashville. I have investigated a number of cases of scarlet fever in the negro, and until desquamation occurs there is little ability to diagnose it.

DR. J. B. NEIL, Nashville: Did you ever see a case of scarlet fever without sore throat?

DR. COYLE: No, but I have seen many other conditions with sore throat.

DR. W. F. GLENN, Nashville: A thought as to how cases become epidemic. Take what the doctors themselves do. We have our office hour, and before the office time we go out, wearing perhaps a woolly overcoat, to see one patient where there may be scarlet fever, and, without even washing our hands, from there we go to another place to treat children, and thus make a number of calls before returning to our office. Let the gentlemen who treat scarlet fever, attend scarlet fever cases only; where the patients can pay the charge, let them pay it, and where they cannot let the city pay the expenses. I am sure I have carried scarlet fever, and I am sure other physicians in this city have carried scarlet fever, to their sorrow.

DR. W. A. H. COOP, Nashville: The diagnosis of scarlet fever in the early stages is not always possible. For instance, a woman attended the birth of a child in a neighborhood apart from where I was then practicing, and returning home she developed a violent sore throat. I considered it only a very bad case of tonsillitis. I made no effort at isolation. What was the consequence? The entire family became affected; the disease lasted from midwinter to July or August, and many infants died from it.

DR. J. B. COWAN, Tullahoma: The question of scarlet fever is especially interesting. Probably, of all the exanthemata, we have no disease so contagious as scarlet fever; and no other disease where the contagion will remain in the room so long. It has been said you have had scarlet fever in Nashville for ten years. Have your rooms been thoroughly disinfected? And have you observed the rules for stamping out that poison in your rooms? What method have you used in doing it? I have known scarlet fever to occur when there was not another case in the city, in a room where there had been scarlet fever seven years before. That room had been repainted and repapered. I have known it, in other cases, to occur after two or three years. I have known erysipelas to occur after two years.

Nashville is not the cleanest place in the world by a good deal. I doubt if you have accomplished much in this respect, and so I think you have the germs here now. Somebody said something about the ignorance of the people in the country letting it come to the city. Why, we have never had an epidemic, and we have had only five invasions in the town I came from, and these came from Nashville; were sent there by the doctors. Every single case was sent from the city of Nashville. Ignorance does not allow it to come only from the country into Nashville, you see. When we undertake to stamp out scarlet fever, we usually accomplish a good deal by the patient dying and being put in the ground; but then we should go to the house and burn everything we can—I don't know whether boiling will do or not. (Question: Burn the house?) I suppose that would be a good idea.

As to the different diagnosis. I believe you can differentiate between measles and scarlet fever, and small-pox and scarlet fever. But I wish to say that I have never seen an epidemic of diphtheria or of scarlet fever but I have found cases which I do not believe anybody, even with a microscope, could differentiate. I have seen cases in the same family which I could not, and I do not believe any man could, differentiate.

DR. HOLSTROM: In 1888 I moved into a house, and fifteen days thereafter my children were taken down with scarlet fever. I had moved to the country. I had not been anywhere, and they had not been anywhere to come in contact with it. My first case was an attack of scarlet fever sore throat. The next, a little girl, had quite a high temperature and then an eruption. About three years previous a child had died in the same house of what was called membranous croup. In the last year, 1894, there were six cases of scarlet fever in the same house. These occurred after a family had come in and repapered and fixed the house. I believe it would be necessary to burn everything and destroy the house. We have had scarlet fever here for seven years. One family moved out of this house and another moved in, and I do not believe we have disinfected it. After a case of scarlet fever is over, the doctor leaves the card up, and an officer goes to the room and disinfects it. I am satisfied the case that occurred in the house I referred to, which was reported to be membranous croup, was scarlet fever. As Dr. Tucker, who, of course, was called in, will know, the first two cases appeared to be diphtheria, but four of the children had scarlatina. We put up a diphtheria card. I believe the germs were there for six years.

DR. BRADLEY: I would like Dr. Glenn to explain the position he takes regarding physicians scattering this disease. I am satisfied we all do that. I am satisfied I did, and then I know I lied like a puppy to my patrons when I said I had not and that it was conveyed through the air. But Dr. Glenn, I believe, takes the position that there should be two or three physicians in every city to attend to these cases of contagious disease. I would like Dr. Glenn to explain to us how we may know whether we have a case of scarlet fever if we do not make at least one call. Suppose he has a dozen cases to see to-morrow in the city. He calls and sees one, and turns it over to another doctor, and then goes on to see his other eleven cases. The next day he will probably find another case to turn over to the other doctor. In the country there is only one physician within five or six miles, and you will get a "right nice cussing" if you call a neighboring physician to treat a case of scarlet fever. I am opposed to scattering the disease. I have not half enough clothes to change every time I see a case, but I, for one, will wear a different suit while treating these cases.

DR. G. A. BAXTOR, Chattanooga: I dislike to hear or to feel that we have no power over these epidemic forms of disease. For one, I am thoroughly convinced of our power of choking them out of existence, provided we can once know them sufficiently to get our fingers on their throats. It is the letting up too soon; it is the failure to watch the patient until desquamation is complete; the failure to personally disinfect the patient after desquamation is complete; not the two or three days before a certain diagnosis can be made that permits the spread of these diseases. Oftentimes it is due to letting the patient out of the room with the clothing on, and then disinfecting the room when the ram has jumped the fence and the flock has followed and you cannot stop them. We have to control them from the first, and throughout, and constantly, and not leave it to the Health Officer or anybody else. That part of the work belongs to us as much as treating the child for the safety of the child's life.

I know scarlet fever cannot always be diagnosticated. Certainly there are many cases which cannot be diagnosticated at all at first, but none of us see a case of sore throat, especially during an epidemic, without scarlet fever occurring to our mind, and diphtheria and tonsillitis, and three or four of those things, and we are on our guard until our diagnosis is absolutely complete.

The idea to me is a repugnant one, that infection cannot be destroyed in a house. I know to the contrary. Boiling, at 212° F. will kill any germ in the world, if the boiling is continued long enough. Again, we have germicides that need not be mentioned. If you properly close the room and properly sulphur it, you have absolute safety. I would as soon take my children into a room a week after a case of scarlet fever, if I can go over the room, as I would after any other septic trouble. Boiling for half an hour will kill any germ. If you wash the paint and walls, if necessary, with corrosive sublimate, and sulphur it properly while the walls are damp, you will render it safe. But if you do not do that, infection may remain, not only one year but a dozen.

DR. ROBERTS: There are two features in connection with scarlet fever that to a certain extent cause both practitioners and people to be somewhat negligent. So many cases occur that are very mild; and people are loathe to take heroic preventive measures. As to the measures spoken of by Dr. Cowan, the objection is, that so often we see one case in a family with three, half a dozen, or more children all housed up together for twenty or twenty-five days, and not another case develops. How often does that occur! At least half a dozen times in my experience during the last winter. In a family of six, ranging from an infant at the breast to children thirteen or fourteen years of age, a typical case of scarlet fever occurred. The house was quarantined, and the family kept in the same room, even on the same bed; the case passed through all the stages; and yet not a single other case has occurred there, although that was in 1894. You cannot get the people to take heroic measures in these cases. Isolation is very different from thoroughly stamping out the infection. It will modify it and lessen it to some extent.

The vitality of the germ varies remarkably. Besides, it is so portable. In my country practice, I have seen an isolated case occurring with no other case for miles around. One case occurred in a newly built house, with no other case I knew of within ten miles, and the child had not been off the place for a long time. Some other member of the household must have brought it there. In the adjoining county of Sumner, I was called to see a family living in a new house. After some eight months' residence in the house, one of the children, some seventeen or eighteen years of age, contracted the disease. She was before apparently in good health and had not been off the place for a long time. I noticed a pair of shoes in the family, which were evidently new. I found they had obtained them from a certain store. I happened to have been in that store a short time before and asked the keeper how he was, and he replied, all very well except one child had scarlet fever. The result, I think, was the development of a case in a place at quite a distance.

DR. KELLY: I think the remarks concerning the stamping out of scarlet fever will scarcely be very generally accepted. Still, that none may be confused with the idea that the germs of any of these diseases may be destroyed by fifteen or twenty minutes or half an hour or two hours' boiling, it is only necessary to refer to the experiments, which show the germs may be destroyed, but the spores will not be destroyed. This experiment can be tried by any of you at the office, and you will find after a few days the germs present again. Boiling does not destroy the spores, but does destroy the vital germs. The curious fact that some people can occupy a bed where a scarlet fever patient has died and will not contract the infection, is often a stumbling block to the stamping out of the disease. The people become careless. Why physicians do not carry the disease oftener than they do we cannot explain. The fact that it is transferred from one place to another is in favor of nothing, but the specific germ is heavy, and tends to sink on the carpet and clothing; the physician carries it only on the lower part of his clothing, gets into his buggy, and it gets in the rug and is carried about in that way. In my opinion, a bath and scrub and shave are altogether unnecessary, especially if the clothing, and particularly that of the lower part of the body, be changed.

DR. J. B. MURFREE: In my experience the contagiousness of scarlet fever is not greater than that of other infectious diseases. It is a fact that the area of infection is limited to within a few feet of the patient. It is less portable than the contagion of any other disease. It is susceptible of being destroyed by fumigation and disinfection. One case comes to my mind at this time. It was a well marked case of scarlet fever in a family of six young children, and a family where other children were coming and going. After the child recovered the room was disinfected, and there has not been a case of scarlet fever among the other children nor in the neighborhood. Another case. In the country a number of children were gathered together in a small room. The disease had been brought to the home, and a little child died in forty-eight hours, yet in that family there were three other chiidren in the same room that the little girl died in, and not one had the disease. It is a question whether or not it is atmospheric borne. I have seen cases of scarlet fever, time and again, where I

could not trace it; and I have seen cases, with other children in the room, without the disease affecting these other children. The idea of scarlet fever remaining in the room ten years and then causing the disease is incredible. Why not consider it as a fresh infection? Surely the poison is not so virulent as the gentlemen would have it.

DR. T. H. MARABLE, Clarksville: I was impressed with Dr. Glenn's idea of conveying scarlet fever. I had never thought of it in that way. I have heard Professor Loomis, in lecturing upon scarlet fever, say that he carried his own child with him, had no hesitancy in going to see a case, coming out and getting in the vehicle with the child. I don't believe that I, nor any other physician, ever carried the contagion in the clothing. We had a marked epidemic of scarlet fever, according to the statement of the health officer, and it devolved upon me, while the health officer was away recuperating, to look after the epidemic. I found the most effectual means of spreading the disease was through the physician: not, however, by carrying the disease in his clothes, but by letting the people intermingle before the desquamation had passed off. I remember one case in which there was a very violent sore throat with only a small patch of eruption on he back of the hand. It was one of the first cases I saw at that time, and I didn't know it was scarlet fever until desquamation occurred, and the hands and the soles of the feet desquamated almost solidly. There was a very fine desquamation of the entire skin, but on the soles of the feet and the hands, desquamation was almost perfect. In that epidemic we had some cases with so very little sore throat that your attention would not be attracted to it. They were not kept in bed, and in a few days desquamation set in and they went through the regular course. I have seen cases there where the temperature did not go above 101°, 102° or 103°.

DR. J. S. NOWLIN, (Closing the discussion): The discussion was rather confined to scarlet fever. My paper was merely on the eruptive fevers, with remarks on epidemic and endemic influence. It seems to be a question whether it is an easy matter to make a differential diagnosis between scarlet fever and diphtheria, without the aid of the microscope. Of course, general practitioners must be governed very largely by clinical features. The paper I read I thought set forth pretty clearly the distinctive symptoms between the two. You will notice, in scarlet fever, the fever runs up rapidly, becoming high quickly. As was said by Dr. Tucker, it is these symptoms which must be kept constantly in the diagnostic eye of the medical man. In scarlet fever the fever runs up rapidly. This is not true with the initiatory symptoms in diphtheria. Whether or not you find an eruption or ulceration upon the skin in scarlatina, you will always find a scarlet blush in the throat. I don't believe I have ever seen a case of scarlet fever in which I could not discover this. You can see the evidence of it in the throat, on the fauces and on the cheek. Diphtheria presents itself as a disease of the tonsils, sometimes involving the uvula and the surrounding tissue; but this symptom involves the whole surface visible when you open the mouth, although not marked in some instances. How often we hear it said that the strawberry tongue is peculiar to scarlet fever. As I understand it, in a strawberry tongue there is a white coat, through which the red papilla are seen protruding. As an almost universal rule it is a black coat. In diphtheria I never saw a white coated tongue.

DR. O. C. OMOHUNDRO, Nashville: This is the first subject before this Society at any time where there has not been a word said about treatment. The idea seemed to be to disinfect the room and give attention to the inmates of the house, but not the treatment of the patient. As to disinfection, I think that rooms can be thoroughly disinfected by using two ounces of sulphur to each hundred cubic feet in the room. One mistake with many gentlemen is that when they go into a sick room they remove all unnecessary objects and the whole paraphernalia of the room, which is already infected, and then, after the patient is convalescent, they disinfect the room. Now, I would suggest that we should move everything out of the room, not forgetting books because numerous instances of books having propagated the disease have been reported, and disinfect them thoroughly at the very first visit we make to the room. Then take charge of the patient, and let the treatment be on

general principles. For six weeks afterwards the patient should be confined to the room because we knew the infecting material is given off by the patient for six weeks. I think it should be taught that patients, before they go out, should be thoroughly washed with the carbolized oil. There should be a disinfecting fluid in the room, in which the physician can wash his hands. The disease is propagated by close proximity. I would especially impress you with the importance of treating the inmates of the house as suspects. Isolate the one infected, from the children in the house but treat the latter with disinfectant washes or gargles for the mouth, and, if any be in poor health, with constitutional treatment. We must attribute to the condition of the patient the difference in the disease in different families. If we use disinfectants in the throat, it will render the poison less noxious. With this treatment, I have had very little of serious throat complications.

DR. TUCKER: There is an idea prevalent among the people, that there is a difference between scarlatina and scarlet fever, and as a consequence cases of scarlatina are regarded as trivial, of little danger, although it can, we know, cause scarlet fever in the most malignant form. If we could impress the people that these names are synonymous, it would help us much in caring for this condition.

MANAGEMENT OF TYPHOID FEVER.

Professor F. C. Shattuck of Boston, has for the past two years given to typhoid patients, who seem able to bear them, raw and very soft boiled eggs, custards, animal broths, strained gruels, ice-cream, junket, blanc-mange, and even scraped or very finely minced meat, in addition to their milk, watching the stools, of course, for the apearance of undigested food. He believes in giving as much and as wide a range of food as each individual patient can digest, and as will not prove irritating to the ulcerated intestine, with plenty of water internally to promote the elimination of soluble poisons. He does not regard with much favor the use of the so-called intestinal antiseptics, and prefers small doses of the salicylate or subgallate of bismuth, the astringent properties of these compounds being naturally taken into account in their administration. He often gives a preliminary dose of calomel, especially in cases seen early and without pronounced diarrhœa. He resorts to enemata of water every second day when there is constipation, and to morphia to mild narcotism where there is intestinal hemorrhage. He does not approve of controlling the fever by means of drugs, and only now and then gives an occasional antipyretic dose in cases in which the headache or pyrexia produces such discomfort as to warrant it. Phenacetin he believes to be the safest of these remedies.

He has used the Brand method in hospital practice, and of 236 cases treated expectantly and with cold spongings 23 died—a mortality of 10 per cent. For some years past the cold spongings have been made much more efficient in the Massachusetts Hospital by rolling up the rubber sheet placed immediately under the patient at the sides so as to form a trough. Water at 60° F. (15.6° C.) is used, sometimes water with a little ice in it to make up for the heat absorbed from the body. One attendant can use cold water in this way, while two are almost indispensible for the tub-bath, with affusion to the head and friction to the body. A temperature of 102.5° F. (39.2°C.) is regarded as an indication for cold water.—*Boston Medical and Surgical Journal.*

CURRENT LITERATURE REVIEWED.

IN CHARGE OF ELLISON J. MORRIS, M.D., AND SAMUEL M. WILSON, M.D.

THE AMERICAN JOURNAL OF OBSTETRICS.

Dr. Bache Emmet writes of

Injured Ureters in Abdominal Surgery.

The author had recently to deal with a ureter injured in the removal of a tumor and occasionally in the removal of a calculus it is necessary to open the ureter, usually by a longitudinal incision. When high in the ureter it is better to try to press it upward into the pelvis and extract through a lumbar incision or, if below the pelvic brim to push it into the bladder and remove it through that organ. When distant from these ends a stone may be safely removed by peritoneal incision. The following cases reported by other men are used as illustrations.

A boy eight years of age, suffered from hæmaturia with abdominal pain for sixteen months. Failing to make a satisfactory diagnosis an exploratory incision was made in the left linea semilunaris and a calculus found in the right ureter two inches from the bladder. The wound was closed and healed. Three weeks later an incision as for ligature of the common iliac artery was made and the stone extracted with forceps through a longitudinal incision. The ureter was stitched with fine silk; a drainage tube introduced to the bottom of the wound and the boy made a perfect recovery. Contrary to the opinion of others, the author thinks a stone may be safely removed by trans-peritoneal incision and the ureteral edges united by continuous suture and the peritoneum sutured over it, or a through and through ureteral incision may be made after the abdomen has been opened for any reason. This method has been twice reported. In one case the patient recovered; in the other the suturing was successful but the patient died of peritonitis. This illustrated a prominent obstacle to the use of this method. There is rarely an obstructed ureter without an infected kidney, and this is apt to infect the wound and cause peritonitis. The second case, reported by Fenger, is plainly extra peritoneal—not trans-peritoneal.

When the trans-peritoneal method is used we should use chromicized gut or fine silk continuous or else Glover's stitch suture and then stitch the peritoneum over all, if necessary insuring coaptation by careful trimming of the ureteral edges.

Should a partial transverse incision be accidentally made during an operation a very slight cut may be closed by a stitch or two and covered by peritoneum, but if gaping much the transverse must be changed into a longitudinal cut, to prevent a stricture. To accomplish this two methods are employed: The cut may be doubled on itself and stitched or the ureter may be completely severed and an anastomosis formed, or the proximal end may be implanted in the bladder. Two centimeters of ureter has been excised for stricture near the kidney and the end successfully implanted in the pelvis. Implanting the proximal end in the abdominal wound, the loin, rectum or intestine has usually been very unsatisfactory. Some operators favor implanting the proximal end in the bladder, but the author opposes this on various grounds, particularly if there has been much shortening, and thinks that obliteration by ligature might be preferable. Cushing succeeded by direct suture in one case, but more usually stenosis results.

Experiments made on dogs have shown that the ureter may be dilated and the normal proximal end be slipped into the dilated distal one and fixed there by one or two sutures as has been done by Kelly. The author was forced to dilate a normal distal end enough to receive a dilated proximal one. He then used three puckering sutures, fixed the ends in place with them, completed the closure by sutures at the margin of the slit, and the operation proved a complete success.

Dr. Alexander Hugh Ferguson discusses the

Operative Treatment of Vesico and Recto-vaginal Fistulæ

and after describing various methods which have been in vogue, gives one which has been devised by himself.

The knife is entered an eighth of an inch from the margin of the fistula and a cut made parallel to this around the opening and extending to the vesical mucous membrane, care being taken not to injure the latter. The ring marked out is now carefully separated from the mucous membrane until it can be turned over, when the opening is closed by carefully suturing the fresh edges.

This being done other sutures are entered in the untouched tissue surrounding the part denuded, care being again taken to avoid piercing the vesical mucous membrane. Tightening these sutures forces the flap previously described into the bladder as a ridge, and this seems to insure success.

Other papers in this issue are Remarks on Etiology and Treatment of Pelvic Inflammation, by Dr. R. Stransbury Sutton; Emmet's Operation for Laceration of the Cervix Uteri, by Dr. J. Johnston; The Relation of Chorea and Rheumatism in Children, by Dr. G. Wythe Cook; Abdominal Surgery in China, by Dr. Elizabeth Reifsnyder; Fatal Postpartum Hemorrhage Eighteen Days After Labor, by Dr. E L. Tompkins.

EDINBURG MEDICAL JOURNAL.

Dr. Alexander Bruce reports a case of

Rupture of an Aortic Aneurism into the Superior Vena Cava.

A stone mason, fifty-seven years of age, married, was seen complaining of dyspnœa, and appearing very cyanotic. For five or six years he had had a bad cough which became worse during the last few months. A few days before being seen by the writer he thought he caught cold, as his breathing was interfered with, but he was somewhat relieved by venesection. He had been a moderate drinker, and had a history of an old attack of syphilis. No history of an unusual exertion preceding this attack of dyspnœa. The skin of the face, neck, thorax and arms was cyanotic and œdematous, the abdomen and lower portions of the body normal. There was an elastic swelling above both clavicles, the external jugulars projected as purple cords, but without pulsation and could be emptied by pressure. Over the base of the heart auscultation showed a peculiar murmur. "This was continuous, somewhat like a venous bruit, very loud, having an almost musical swishing sound. The sound was most intense during ventricular systole, almost dying away during diastole."

The point of maximum intensity lay on the sternum at the level of the third costal cartilage. It was propagated toward the right, and it diminished suddenly at the left sternal border, except opposite the fifth cartilage where it could be well heard an inch to the left of the sternum. No albuminuria at first, but it developed later.

Postmortem examination showed an aortic aneurism about half the size of a man's fist extending from the valves to the origin of the innominate artery. It had pushed the superior vena cava backward and there were two ulcerations into it—one about one-quarter and the other about three-sixteenths of an inch in diameter. The large veins in the neighborhood were greatly dilated, and the trachea and bloodvessels were surrounded by a dense fibrous mass in which was found a node supposed to be a gumma.

The attending physicians had noticed that the point of greatest intensity of the murmur had suddenly risen from the third to the second cartilage. This was explained postmortem by finding the two ulcers into the vena cava, the upper being of more recent formation.

BROOKLYN MEDICAL JOURNAL.

At the Brooklyn Surgical Society, a case was reported of injury to the posterior interosseus nerve in reducing a dislocation and fracture at the elbow. The subsequent paralysis disappeared without operation.

Tuberculosis of the head of the humerus was mentioned as a comparative rarity in adults, and a case was reported in which excision gave a useful arm. In children continuous extension is easily maintained by slinging the wrist to the neck but results of course in anchylosis.

In the *Physician and Surgeon.* Dr. J. R. Dodge writes of

The Rectal Tube.

Two cases are recorded; in one of which a diagnosis of malignant stricture of the colon was made and could be confirmed in no other way until the autopsy. In the other case a man had intussusception of the colon and, positively refusing operation, was finally relieved by a forcible injection through a long rectal tube. The report is very interesting on account of the heroic treatment used.

Dr. C. H. Hughes gives a psycopathical apology for Cain's fratricide—inspired by Mark Twain's lament for Adam.

NEW ORLEANS MEDICAL AND SURGICAL JOURNAL.

Dr. Thomas Y. Aby writes of

Continued Fever.

The disease referred to seems to the author to be displacing the severe malarial fevers formerly seen in his neighborhood, and he gives the chief characteristics as follows: Males are much more frequently attacked than females, nursing infants never, and elderly men rarely if ever, Africans though rarely attacked have the disease severely and lasting for a long time when attacked; rich and poor suffer equally, and although formerly seen during the summer and fall months, it now appears throughout the year.

Personal observation led the writer to believe this disease due to faulty excretion of tissue waste (not to a specific germ) but recent port-mortem investigations by other men seem to show it to be an atypical typhoid.

The poison seems incapable of elimination through the skin, liver, kidneys, etc., and the duty seems to fall on the mucous membrane of the small intestine. The author's reason for holding this view being that while the liver, kidneys, etc., are acting normally, and there is usually no tenderness anywhere, the stools will be found with an unusal amount of mucus, indicating an engorgement and unusual secretion in the intestinal coat, and this he believes to be the means adopted for the excretion of the poison.

The course of a typical case is as follows: Usually after a varying period of malaise the patient goes to bed and is seen with a pulse beating between ninety and one hundred and twenty and not varying with the temperature; which is usually between 100° and 102° in the morning and slowly rising from one and one-half to three degrees toward night, the tongue is usually pale, clean, and moist in the morning and may get harsher toward night. The appetite is poor; but the other symptoms common to most fevers, flushed features and thirst are much less marked. There is apt to be some constipation, and the abdomen soft and flat except for some rigidity of one of the recti. Nausea, vomiting, and pain of any kind, even headache, and de-

lirium of any degree even with continuous high temperature are usually absent.

The author can recall no exception to the rule of absence of delirium. Without showing any effect from treatment this condition goes on for probably from ten to thirty days, and then begins slowly to abate. After disappearance of fever, recovery is rapid and as after yellow fever better health is usually enjoyed than before the sickness.

The absence of headache in a case of fever particularly if any tension of the recti could be discovered would suggest this fever, for there are no pathognomonic symptoms.

In regard to treatment—after making use of all the recognized remedies for similar conditions the author has learned to depend on opium—a teaspoonful of camphorated tincture or fifteen or twenty drops of laudanum to an adult every six or eight hours by the rectum. In defence of his use of this drug the author states that he does not think that it stops secretion in these doses, but allays irritation and therefore may appear to do so. Other drugs may be used if symptoms calling for them seem prominent.

Where the patient cares for it butter milk seems the most satisfactory food, and is given to the extent of about a quart daily. If averse to butter-milk, soups, broth, beef essence, etc., may be used, but never solid food, nor, the author says, sweet milk. Lemonade, soda water, etc., are allowed as desired.

Food is given every three hours from 6 A.M. to 9 P.M., at which time the fever is usually at its height, and a tepid bath being given the patient is not again disturbed until morning.

PERISCOPE.

IN CHARGE OF WM. E. PARKE, A.M., M.D.

SURGERY.

Hypertrophy of the Mammary Glands.

The diffuse form of hypertrophy of the mammary gland is known to be extremely rare. According to Roger Williams, out of 2,422 cases of mammary neoplasms which were consecutively under treatment in four London hospitals during a period of from 16 to 21 years, only six cases of diffuse hypertrophy were seen. In this connection, then, a case just recorded in the *Journal of the American Medical Association* by Dr. J. B. Hamilton is of more than ordinary interest (*Med. Press*). The patient was thirty-two years of age, and had been married eighteen years when she came under treatment for enormous hypertrophy of the breasts. The right breast measured 30 inches in circumference at the nipple and the left 39. The right breast also measured 30 inches around the pedicle and the left 27. Again, from the nipple to the pedicle the right measured 14 inches and the left 13½. The patient was unable to walk without assistance owing to the great weight and bulk of the organs. The first step in the operation for the removal of the right breast was that of passing two long pins through the pedicle, and tying the pedicle tightly between the pins and the chest. The breast was then removed by cutting two flaps of skin from the tumor, reflecting them respectively upwards and downwards, and enucleating the glands; the vessels were secured without difficulty. The hemorrhage was considerable, but it was almost entirely from the blood remaining in the gland. After removal the gland was found to weigh 27½ pounds. The wound healed by the first intention, and the patient did well. About three weeks after the first operation the left breast was similarly removed, and the combined weight of the two glands amounted to no less than 50 pounds. The patient made a good recovery after the second operation.

Dry Surgery in Germany.

The American practitioners and student of medicine who have been trained to look upon irrigation as essential to the aseptic handling of wounds in their after-treatment, are always quite astonished at the apparent diregard the German surgeon seems to have for this method of securing good results. While in Gottingen, I was present every dayat the surgical polyclinic held daily by Professor Rosenbach, and I do not believe I saw a drop of water or other irrigation fluid used during the whole time. The patient is brought in, the dressing removed, the wound examined, squeezed lightly, oozing pus is wiped off and dressings, dry or wet as may be necessary, are reapplied. Even in the treatment of deep abscesses, or where neurotic processes are going on, irrigation is never resorted to, the surgeon seeming to have all faith in his drainage tubes, without resorting to the stream of bichloride water as used by our American surgeons. They probably get just as good results here in Germany as we do in the United States, but their methods of wound-handling are certainly not so cleanly as those used in the latter country.

Simple Treatment of Ganglion.

Duplay (quoted by *Lyon Medical*) describes a simple, safe, and invariably successful treatment for this troublesome affection. This consists in the injection of a few drops of iodine into the cyst. Such injections must, of course, be practised under antiseptic precautions, the needle being driven in

at the point where the cyst is most prominent, the skin having first been drawn aside so that a valvular opening is made. The cyst is not previously evacuated, but the iodine is driven directly in. A small antiseptic dressing is applied with a bandage. Cure is accomplished in five or six six days. Sometimes in large cysts a second injection is necessary.

The Influence of Fatigue on the Auditory Functions

The New York *Medical Journal* says that in order to study this question, the author made examinations of twenty-four bicycle-riders after they had ridden thirty two miles in two hours and a quarter. Two of the men complained of subjective noises only, while in nearly all of them the perception of sounds by ærial conduction was less marked than in the normal condition, and Rinne's experiment showed negative results. In the riders who were subjected to an examination with tuning-forks a slight diminution in the perception of loud sounds was ascertained. The only lesion noticed was a slight hyperemia of the drum membrane.

The competitors were again examined after a rest of from two to seven hours, and in six of them the auditory power was found to be the same; in two it was not so good, and in the sixteen others it was better, the ærial perception having increased from a few centimetres to a meter and a half, and Rinne's experiments gave positive results. The men in whom the amelioration was the most marked, in whom, consequently, the hearing had undergone the greatest change, were whose who had had little experience or training.

Physicial fatigue, says the writer, evidently causes a temporary weakening of the auditory power. This fact demonstrates, besides, he says, that the effects produced by great physical exercise are not shown by muscular fatigue only, but they remotely affect the entire organism and especially the nervous system, and the special senses, on account of the delicacy of their functions, are more likely to reveal the effects. The enervation shown by birds of passage after a long flight is a phenomenon of the same nature as that observed by the author in the examinations referred to.

The Treatment of Floating Kidney.

Riedel (Reineboth in *Cent. f. Chirur.*) performed nephrorrhaphy in eight patients. As a result of this experience it was found that sutures made to include the renal structure and surrounding adipose tissue were insufficient for the purpose, and suture of the fibrous capsule alone by means of a catgut was subsequently substituted. This, however, only permits of fastening of the lower half of the organ, or that portion which projects below the twelfth rib, and fixation of the upper half must be accomplished by some other method. This is done by splitting the fibrous capsule for its entire length at the posterior edge of the kidney, loosening it from its attachments to the latter as far as possible, and tamponing the space thus formed by means of a strip of iodoform gauze. The gauze is pushed as high up as possible between the exposed renal surface and the diaphragm. The remainder of the wound is allowed to remain for several weeks, and upon its removal two broad granulating surfaces are to be found lying opposite to each other. These become attached in the future progress of the healing, and the kidney thus becomes secured along its whole posterior border. The results thus far obtained are sufficiently encouraging to warrant further trial of the method.

The Differential Diagnosis of Infantile Scurvy.

Dr. J.H. Fruitnight (*Archives of Pediatrics*) summarizes our knowledge of scorbulus as follows:

It is the result of a faulty nutrition which leads to a deviation from the normal chemical composition of the blood, probably a deficiency of its alkalinity.

The disease is characterized by a blood dyscrasia accompanied by structural changes in the coats of the blood-vessel.

The bone and joint lesions, the spongy condition of the gums, and the petechiæ constitute a triad of symptoms highly pathognomonic of the disease. One or both of the two last named symptoms may be lacking.

The order of development of the symptoms seems to be: First appear the tenderness and swellings of the lower extremity, then the sponginess of the gums, and finally the hemorrhagic extravasations.

Under the treatment these symptoms begin to improve in the same order of sequence, the epiphyseal lesions disappearing more rapidly than the other two.

If there be any doubt of the diagnosis of a given case, recourse should be had to the therapeutic test of an antiscorbutic regimen, which will by its results, in a comparatively short space of time determine the question beyond cavil.

The prognosis is nearly uniformly favorable under proper treatment, and the likelihood is that as physicians become more familiar with and competent in diagnosticating the disease, its mortality will be reduced to nil.

The main principle involved in the treatment of infantile scurvy is comprised in the institution of antiscorbutic dietetic measures.

Loeffler's Solution for Topical Use in Diphtheria.

Methol	10 grains
Toluol	36 cubic cen
Absolute alcohol	60 cubic cen
Solution of ferric chlorid (U. S. P.)	4 cubic cen

When much sepsis exists, two cc. of creolin or metacresol, are substituted for the ferric chlorid solution. We should prefer gualacol. The therapeutic value of this solution is attested by many competent observers. The application is quite painful, and cannot be born by the nose or larynx. —*Polyclinic.*

The Use of Cocaine to Prevent Respiratory Disturbances During Chloroformization.

It is quite possible that others have been struck by the ease with which a patient whose tonsils and post-nasum have been pencilled with a solution of cocaine previous to the use of chloroform takes the anesthetic. For some time I have practiced this use of cocaine in tonsillotomy and removal of adenoids after having noticed the comparative freedom from hemorrhage in a case where I attempted, but without success, to operate under cocaine alone, and had to give a general anesthetic. In this case the tonsils were removed with very little hemorrhage indeed, and I was able at once to remove the adenoids unhampered by hemorrhage from the tonsillar stumps. Apart altogether from the fact that cocaine thus used eases the subsequent use of chloroform (or ether), this circumstance of the freedom from hemorrhage in an operation (tonsillotomy), where such is always dreaded, ought to be freely observed. Before the action of the cocaine is over the patient is already conscious, and ice can be employed to prolong its effect. I should say that the cocaine, which need only be applied in weak solutions (two per cent.), reduces the loss of blood in the double operation of removal of tonsils and adenoids by over fifty per cent.

Rosenberg, of Berlin, has recently drawn attention to the fact that if the mucous membranes of the upper air-passages are anesthetized by cocaine before the administration of chloroform, the disturbances consequent upon their irritation are obviated. This author has found by experiments that at the beginning of anesthesia, if the blood pressure be considered as equal to 100, the systole is represented by 210, and the diastole by 40. Under normal conditions, on the contrary, the blood pressure being the same, the systole is represented by 110, and the diastole by 90. These modifications are due to respiratory disturbances consequent upon irritation by the chloroform of the mucous membranes of the upper air-passages. In two or three cases of my own where this combination of general and local anesthesia has been employed, less chloroform has apparently been used, and the patient went under with less struggling and fright, and more quickly. In strabismus operations cocaine furnishes a field free from hemorrhage, but as it abolishes sensation in the conjunctiva, it might prove embarrassing to the chloroformist.— *William Robertson, M.D., in British Medical Journal.*

Aristol in Oral Surgery.

In a comprehensive treatise on "Diseases and Surgery of the Mouth, Jaws, Teeth and Associated Parts" by Dr. James E. Garretson, which has been just issued from the press of J. B. Lippincott Company, the author speaks as follows of Aristol;—"This powder is to be highly recommended for its antiseptic and curative qualities. Advantage over iodoform lies with absence of odor. Aristol is an amorphous powder of red-brown color. It is insoluble in cold water and glycerine. It dissolves in chloroform, ether and benzine. Water heated to 140° F. dissolves it. It is also reasonably soluble in alcohol. Aristol is not toxic nor are there recorded any cases of ill results attendant on its use as a surgical dressing. Sifted over ulcers or used dusted upon the seat of a surgical operation its use proves most satisfactory. A salve made by rubbing it up with vaseline is highly recommended: of the prescriber proportions may vary at pleasure." In the chapter on epithelioma Dr. Garretson comments as follows on theuse of Aristol: "The author has found muchservice in the free employment of chlorate of potassium in a finely pulverized form. This powder is furnished the patient and he is directed to apply it freely. Where the chlorate of potassium fails, trial of Aristol is recommended by Dr. Brocq, who claims to have secured by its employment most satisfactory results; the application is entirely painless; its use is restricted to ulcers of superficial character.

Local Application of Carbolic Acid.

Cerne, of Rouen, reports the two following cases in the *Normandie Medicale:* A diabetic male had an insignificant wound of the leg dressed with a compress wet with a weak carbolic acid solution; this produced gangrene which increased in size daily. The patient went to an empiric who replaced the carbolic acid by an ointment of some sort and the gangrene was arrested. The second case was that of an alcoholic, with sclerosis and perforating ulcer of the left great toe; this was dressed with a carbolic solution of 1 to 40; on the second morning all the end of the toe was gangrenous. These cases show the dangers which may result from the local application of carbolic acid, especially if made by the patient himself—that is to say, without precaution or measure. Caution should be exercised in the use of carbolic dressings; the danger is greater when, from any cause, the tissues have less than their normal vitality.

Treatment of Hydrocele.

A letter from France to the *Med. Press and Circular* says that the classical treatment of hydrocele, puncture and injection of tincture of iodine or some other irritating liquid, has been rendered much more simple by a surgeon who has published the result of several cases cured rapidly by the method. He inserts the trocar into the most dependent part of the tumor and removes the liquid; he then injects a five per cent. solution of carbolic acid, which is removed almost immediately. The trocar is introduced a second time into the canula, and pushing it up toward the highest point a counter-opening is made. The trocar is again withdrawn, and a drainage tube is passed through the canula and left in position, the canula being removed. The patient can immediately get up and walk about. The drain is withdrawn on the fourth day and in a week the man is cured.

Catheterization of the Ureters

Dr. Brown, in Johns Hopkins *Hospital Bulletin*, states that with Brenner's modification of Leiter's cystoscope he has found little or no difficulty in catheterizing the ureters in the male or female subject.

The bladder should contain from 150 to 200 c.cm. of fluid or even more. The writer then passes the anterior cystoscope and takes a complete survey of the bladder. This having been done he replaces it with the Brenner instrument which is passed with the stylet fixed.

The ureteral orifices are next searched for, and when these are found the stylet is removed and the catheter inserted and passed nearly to the inner opening of the canula. The ureteral orifice is again sought for and the catheter passed into it. To prevent kinking of the catheter and to guard against exerting undue traction upon the ureteral orifice the cystocope must be kept in line with the catheter so long as the latter is within the ureter. Sometimes it has been found advantageous to give the catheter a slight curve at the tip. Nitze claims that the difficulty in catheterizing the male ureter is greatly lessened by passing through a special canal fixed to the cystocope an elastic catheter, the end of which is made to take a direction when in the bladder corresponding to that taken by the lower extremity of the ureter as it passes through the vesical wall.—*N. A. Practitioner.*

ARMY AND NAVY.

CHANGES IN THE U. S. ARMY FROM MAY 12, 1895, TO MAY 18, 1895.

Captain Charles Richard, Assistant Surgeon, will when relieved from duty at the Military Prison Fort Leavenworth, Kansas proceed to and take station at St Louis, Missouri, for duty as Attending Surgeon, and Examiner of Recruits.

Captain Peter R Egan, Assistant Surgeon, is relieved from duty at Fort Custer, Montana, and ordered to Fort Assinniboine, Montana for duty, relieving Major Charles B. Byrne, Assistant Surgeon. Mayor Byrne on being thus relieved is ordered to Fort Snelling, Minn. for duty.

Major William C. Shannon, Surgeon, upon the expiration of his present leave, is ordered to Fort Custer, for duty.

1st. Liet. Deane C. Howard, Assistant Surgeon, will be relieved from duty at Fort Snelling Minn. upon the arrival there of Major Charles B. Byrne Surgeon, and will then proceed to Fort Custer, Montana, and report for duty, at that post.

Captain Alonzo R. Chapin, Assistant Surgeon, having been found by an Army retiring board incapacitated for active service on account of disability incident to the service, is by direction of the President retired from active service this date May 10, 1895.

Leave of absence for four (4) months, to take effect on being relieved from duty at Fort Thomas, Kentucky, is granted Captain William J. Wakeman, Assistant Surgeon, U. S. Army.

CHANGES IN THE U. S. MARINE HOSPITAL SERVICE FOR THE FIFTEEN DAYS ENDING MAY 15, 1895.

Wheeler, W., Assistant Surgeon: detailed as Chairman Board for Physical Examination of applicant for appointment in Revenue Cutter Service, May 13, 1895.

White, J. H., Passed Assistant Surgeon; detailed as Recorder Board for Physical Examination of applicant for appointment in Revenue Cutter Service, May 13, 1895.

Carrington, P. M., Passed Assistant Surgeon; granted leave of absence for fourteen days, May 4, 1895.

Cobb, J. O., Passed Assistant Surgeon; granted leave of absence for fourteen days, May 1, 1895.

NEWS AND MISCELLANY.

Deer Park on the Crest of the Alleghenies.

To those contemplating a trip to the mountains in search of health and pleasure, Deer Park, on the crest of the Allegheny mountains, 3,000 feet above the sea level, offers such varied attractions as a delightful atmosphere during both day and night, pure water, smooth, winding roads through the mountains and valleys, and the most picturesque scenery in the Allegheny range. The hotel is equipped with all adjuncts conducive to the entertainment, pleasure and comfort of its guests.

The surrounding grounds, as well as the hotel, are lighted with electricity. Six miles distant, on the same mountain summit, is Oakland, the twin resort of Deer Park, and equally as well equipped for the entertainment and accommodations of its patrons. Both hotels are upon the main line of the Baltimore and Ohio Railroad, have the advantages of its splendid Vestibuled Limited Express trains between the East and West. Season excursion tickets, good for return passage until October 31, will be placed on sale at greatly reduced rates at all principal ticket offices throughout the country. One way tickets, reading from St. Louis, Louisville, Cincinnati, Columbus, Chicago, and any point on the B. & O. system to Washington, Baltimore, Philadelphia or New York, or vice versa, are good to stop off at either Deer Park, Mountain Lake Park or Oakland, and the time limit will be extended by agents at either resort upon application, to recover the period of the holder's visit.

The season at these popular resorts commences June 22d.

For full information as to hotel rates, rooms, etc., address George D. DeShields, Manager, Deer Park, or Oakland, Garrett County, Md.

ARTICULAR RHEUMATISM: ULCERATION ENDOCARDITIS; EMBOLISM.*

CHARLES CARY, M. D.,† Buffalo, N. Y.

I purpose showing you this morning, the clinical picture of a serious and not very common malady and, as an introduction, I have brought before you a patient whom you have seen in the ward-class and whose disease is a comparatively common one.

This man is 48 years old; he is employed in the railroad yards, doing both indoor and outdoor work and, therefore, exposed to sudden changes of temperature and compelled to undergo the vicissitudes of the weather. He is now recovering from a moderately acute attack of articular rheumatism. It is acknowledged by almost, if not quite, every authority that such exposure as he has undergone, is the exciting cause of the outbreak of rheumatism. It is a disease to be found among the drivers, the street-car and railroad men, the mechanics who are at work for long hours out of doors; in short, it is to be expected among all who for any reason are exposed to the inclemency of the weather.

The patient represents the type of man physically, that is apt to be affected with this disease. He is in the prime of life, apparently well nourished, and he has had no other illness since the usual fevers of childhood. Acute articular rheumatism seems to have a predilection for the hearty, well nourished, wholesome individual. It usually, however, makes its first appearance earlier in life. The left knee was the first joint affected but there is no longer any redness or evidence of acute inflammation in this articulation. It is characteristic of this malady that the inflammation leaps from one structure to another, the poison being in one joint on one day, passing to another the next, while the first affected joint regains its normal condition in a few days, sometimes in a few hours, and often invading the endocardium in the course of the disease. Here, the right knee, which was invaded after the left, is still quite tender and distended while the disease has involved also, the right shoulder and some of the smaller joints of both hands. A few days ago, the left knee was greatly inflamed and the patella could be knocked against the femur, showing an effusion in the synovial sac. Sometimes, when the synovial sac is not much distended, the patella is not forced up from the condyles and, in order to elicit the sound of impact against the femur, it is necessary to press over the upper part of the joint cavity so as to squeeze all the fluid into one part of the sac. In the left knee, this sign can no longer be obtained, but in the right knee I can get the sensa-

* Clinical lectures at Buffalo General Hospital.
† Prof. of Materia Medica and Therapeutics, University of Buffalo.

tion of impact though, on account of the small distance that the patella can move, you can not hear the sound as you could in a more recent case.

The patient has had a very painful illness, the suffering of articular rheumatism being greater than for many more serious diseases. There is a time-honored comparison between rheumatism and gout which likens the pain of the former to that produced by putting a limb in a vise and screwing it up as far as possible, while the pain of gout is stimulated by giving the screw one more turn. I believe, however, that the comparison was made by a gouty subject and that acute rheumatism is as painful a disease as there is. The patient has not had a very high run of fever; for several days, the temperature was about 101°, dropping yesterday to 99°, in the morning and rising again in the evening to 100°. A single sample of the urine was of deep red color, acid reaction, and of a specific gravity of 1024. There was no albumin, sugar or sediment. The patient had copious sweats which were acid and sour in odor. These sweats are characteristic and they are often so acrid that sudamina are produced from their irritation.

In all cases of rheumatism, the heart should be frequently examined, for there is no other malady that so commonly causes endocarditis as does acute articular rheumatism. At no time during the malady has this man presented symptoms of cardiac invasion. It is not so much a surprise to me that rheumatism frequently induces cardiac inflammation as that it does not more often cause it. If you stop to estimate the friction at the cardiac orifice, you will be compelled to acknowledge that part of the heart is subjected to a tremendous amount of wear and tear. You have seen the physiological experiment with a column of mercury of water showing the pressure of the heart on the blood current. It is estimated that the left ventricle of the human heart exerts a pressure of about 55 pounds. Even at an estimate of 50 pounds, with the heart pumping away at the rate of 100 beats per minute, as it has done in this man's case for days, the amount of energy expended in the course of 24 hours is something enormous. Now, if in addition to the mechanical irritation of the rapidly moving blood current, the blood contains chemical poisons, an inflammation is very apt to occur and it locates by preference at those parts of the endocardium where the passage is narrowest and where the friction is greatest, in other words: at the valvular orifices and particularly those of the left side of the heart where the pressure of blood is greater. If, in the process of inflammation, part of the endothelium is raised up above the common level, or if a fragment is detached leaving a raw surface, the conditions are favorable for the coagulation of the blood, and a deposit of fibrin is made, forming what is known as vegetation.

With most maladies, the very name of the disease implies the degree of danger of the case. Typhoid fever, pneumonia, etc. Endocarditis, however, is an exception to this rule. A person may have endocarditis and yet not be sick at all, in the ordinary sense of the word; or he may be extremely ill. The development of rheumatic endocarditis does not, as a rule, materially influence the course of the fever. There is commonly a slight rise of temperature and some irregularity of the heart which calls your attention to it, although your examinations should anticipate any cardiac involvement. In an acute rheumatic endocarditis the heart is evidently laboring under difficulties. Its rhythm is perturbed and you can hear the murmur which the increased friction of the blood current over the roughened valvular orifice causes, or which is due to a slight leakage backward of blood. Too much prominence should not be attached to this sign, for the loudness or softness of the murmur is not proportionate to the severity of the lesion. The symptoms from which the patient suffers are much more significant.

In regard to treatment, the joints were wrapped and the patient was kept very carefully protected with blankets from drafts. He was offered drink very freely, especially in the form of milk and alkaline waters. Meats were excluded from his diet and he had little solid food of any kind. I gave him morphine because I believe it lessens the work of the heart by lowering the vital requirements and by doing away with that part of the cardiac strain which depends directly on pain. Unless there is some reason to fear the establishment of the morphine habit, I believe it is well to introduce morphine in

the treatment of acute rheumatism at the start, in order to throw out as far as possible, the element of cardiac labor which is a determining factor in the production of endocarditis. Salicylates, usually administered in the form of the sodium salt, are indicated to aid in the elimination of the poison and in reducing the temperature. Sixty centigram to one gram doses are given every two or three hours, and pushed to the point of partial relief from the subjective symptoms of pain and fever. Then the doses are diminished or given at longer intervals. The bowel should be kept rather loose by salines, Rochelle salt being given in this particular case.

Like all other infectious diseases, rheumatism will run its course. You do not pretend to abort typhoid or scarlet fever, you simply guide the patient through the disease. By diminishing the patient's suffering, by lessening the amount of poison with which he has to contend, you make him more comfortable and tend to protect him from the danger of cardiac complications, but you probably do not materially shorten the duration of his illness.

ULCERATIVE ENDOCARDITIS: EMBOLISM.

This man is fifty-three years old, single, a German by birth, and a shoe-maker by occupation. The family history is negative except that one sister died of consumption. As to personal history, he had gonorrhœa thirty years ago, and there is a syphilitic history dating back twenty-five years, but the only statements are with regard to chancre—he had no after symptoms. This is an important point, for it throws a good deal of discredit on the supposed attack of syphilis. About the same time he had an attack of rheumatism affecting the arms, hands and legs. This rheumatic trouble lasted five years. Since then, he has been well until about four weeks ago.

Inquiring more particularly as to the rheumatism, I learn that he had palpatation of the heart before the rheumatism, and that there was no very acute fever. It is impossible to say at this late date whether the so-called rheumatism was really rheumatism or not. Four weeks ago he went to bed feeling as well as usual, but when he awoke in the morning he noticed a large yellow blister on the outside of the left leg, which he pricked with a needle and which discharged a quantity of matter. Three or four days later, the sore had become covered with a dry, black crust, which you can still see. It is, evidently, a localized gangrene affecting an area about two inches by one and a-half in diameters, and rudely triangular in shape. Six days ago, he had a swelling of the scrotum and penis. He worked until compelled to go to bed, when he was sent to the hospital. For several days previously, he had had feverat night, at least he thinks so from his sensations, but his temperature was not taken.

I do not know but that I make a mistake in bringing this case before you without having made a further study of his symptoms, but there is something so unusual and interesting about his disease that I prefer to study the case with you and, if necessary, revise my opinion of the nature of the trouble, rather than run any risk of you missing an opportunity that may not present itself again in a long time.

On examining the sore on the leg, we find at least a quarter of an inch of sloughing tissue. Except that it is not at the distal end of an extremity, this looks not unlike a senile slough, and it certainly is an instance of dry gangrene. Occurring without any history of traumatism, we must ascribe this phenomenon to some internal cause which has cut off the blood supply. The dry slough forms a practically aseptic dressing, and the sore interferes with the patient's comfort in no respect.

Let us turn our attention to the scrotum and see if there is any connection between the two lesions. You will frequently see œdema of the scrotum in cases of general dropsy, but here there is no swelling of other parts, and even the swelling of the scrotum, though undoubtedly containing some serum, is not at all what we should speak of as œdema in the passive sense. The penis and scrotum have a hard, tough consistency, the skin is reddened and hot, and the whole appearance is that of an acute inflammation. I apprehend that there is suppuration. The patient's countenance is pallid, the pulse has ranged for several days between 90 and 100, and the temperature has risen to 103° daily since he has been in the hospital. All this suggests an abscess.

The urine for twenty-four hours amounted to 800 c.c., was of a reddish tint, of acid reaction, of a specific gravity of 1018. There was no albumin, no sugar, no sediment. The excretion of urea amounted to 12 grams; about what we should expect for a rather small man on limited diet and with some depressing illness.

The cardiac apex is almost directly beneath the nipple, and its beat can be felt an inch outside the nipple line. The area of cardiac dullness is correspondingly increased. When the patient entered the hospital, the heart was intermittent and irregular. It has now become steadied by the care and medication which he has received, but there are still plainly audible three murmurs, a mitral regurgitant, an aortic direct, and an aortic regurgitant. Before speculating as to whether we can find any logical connection between the results of our examination and the obvious lesions which the patient presents, let us determine exactly what the condition of the scrotum is. An aspirating needle is passed into the right scrotum and apparently through into the testicle, and now pus is withdrawn. The pus is of an extremely offensive odor and is in considerable quantity. After the medical clinic, I will ask Dr. Park to open the abscess freely and evacuate this source of poison.

The explanation that I would offer of the occurrences of this case is as follows: An embolus has lodged in one of the smaller arteries of the leg, cutting off the nutrition from a limited area. This area is so superficial that the necrosis which developed speedily reached the surface and now appears as a gangrenous ulcer. The abscess of the testicle has developed in the same way but, the plugged artery being deeply seated, the process has gone on under cover. Following the embolism, a hæmorrhagic infarction has occurred; that is, from the sudden removal of blood pressure from behind, there has been a setting back of venous blood and stasis. For two or three days, the scrotum was as white as the skin of a dropsical patient and there was nothing to suggest pus.

In many instances, embolism occurs without the formation of pus; why should such a development occur here? Let us refer to the condition of the heart. Whether or not the history of rheumatism is significant, we have the evidence of an endocarditis which, from the enlargement of the heart and the lack of acute illness till very recently, must have lasted for some time. The murmurs at the valvular orifices indicate an inflammation at those sites in particular. Now, if we suppose that one of the little vegetations has become broken off and carried into the aorta, it is simply an accident as to where it may be carried and where it may lodge, but wherever it lodges we should expect the nutrition of the part to be profoundly altered. This accounts for the localized gangrene of the leg; it accounts for the formation of a hæmorrhagic infarction in the testicle, but it does not account for the plainly infectious character of the lesion in the testicle unless we assume that the endocarditis has taken on a septic element and has become an ulcerative or malignant endocarditis. Presupposing this, we can readily comprehend how the embolism has led to a septic thrombosis which has extended, involving the veins in a septic phlebitis, and how, from the breaking down of the tissues, this terribly offensive abscess has formed.

My attention has been called to a difference between the radial arteries of the right and the left wrist. This has no significance, however, as the right fore-arm has been broken and the superficialis volæ is given off at a higher level than usual.

Judging from the record of this kind of cases in the past, I do not feel warranted in holding out a favorable prognosis. With the vegetations on his cardiac valves, he is apt to have an embolus thrown into the blood current at any time. Thus far he has been lucky in having the emboli lodge where they are accessible, but there is nothing to prevent them from reaching deeper and more vital parts. The patient may develop an hepatic abscess, or a similar infectious process may be set up in the brain. It is as much a matter of chance as is the throwing of dice. There is no reason to apprehend any serious trouble from the abscess of the testicle, and certainly we need not concern ourselves about the localized gangrene of the leg. But I know of no means of disinfecting the diseased area at the fountain head of life—the heart. If other abscesses develop, they must be opened.

One other point must be considered, the possibility of a syphilitic infection and consequent heart lesion. If the endocarditis is of this nature, the prognosis is

more favorable. With this hope, I shall order small doses of potassium iodid and some form of mercury, but I shall not stake very much on their therapeutic value. We must support, nourish and stimulate the patient, and at least make him temporarily comfortable. Sooner orlater, the detachment of an infectious particle from the cardiac orifice will determine his rapid dissolution.

NOTE.—A week after the clinic the patient was shown in a state of temporary improvement. He walked into the arena, the abscess of the testicle had been freely opened and had almost ceased to discharge. No perceptible change had occurred in the sphacelus on the leg. The patient was perfectly comfortable. The possibility of other forms of embolism or arterial thrombosis was considered. Diabetes was excluded, and although the patient had eaten rye bread, there was no evidence of ergotism. He was discharged well, with great improvement of cardiac sounds.

CLINICAL NOTES ON A RECENT SERIES OF SURGICAL CASES.*

THOMAS H. MANLEY, M.D., NEW YORK.

The successful practice of surgery is not altogether unlike the cultivation of a garden; the yield will in all probability depend not so much on the richness and fertility of the soil or a favorite season, as on the knowledge, the experience, and the industry of its cultivators.

Though much, in isolated instances, may depend on chance and fortuitous circumstances, our chief reliance, in the end, must rest on the firm groundwork of matured knowledge and extended effort. The cases here submitted, have all come under my care and observation since the first of this year, and are selected because they belong to a class which commonly come before us, and of which it may be said that now, after more than twelve years' experience, in dealing with a very considerable number of them the writer is enabled to report successes and results altogether in advance of what would have been possible at an earlier period. For time and observation have convinced me that even moderate success in the treatment of complicated surgical cases, is utterly impossible without abundant opportunities for practice, together with a familiarity with the latest and the best work of contemporaries in our own and foreign countries.

The cases selected for presentation here are of traumatic and pathological order, regional and general.

CRANIAL LESIONS—FRACTURES OF THE SKULL—TRAUMA.

Since the first of March, 1895, there have come under my care ten cases of fractures of the skull—four basilar, occupying the most vital, the cerebral and cerebellar regions; and six cases of fracture of the vault, the non-vital. The patients ranged in age from nine to fifty-six years; there were nine males and one female; three were fatal, and seven recovered.

It may be said that this class of fracture is yearly becoming more common in New York. The immediate dangers attendant on cranial fracture, arise in consequence of shock, hemorrhage and inflammation. The features of special interest in connection with the cases here enumerated, are, first, those with reference to basilar fracture involving one or more of the cranial fossæ. We had quite unequivocal symptoms of this lesion; as a free discharge of sero-sanguinolent fluid from one or both ears, with a free extravasate into the subjacent tissues.

Traumatic depression of the bone substance of the skull is not attended with such definite symptoms of sensory or motor disturbances as we would be led to expect since the doctrine of cerebral locali-

*Read at the Eleventh Annual Meeting of the Fifth District Meeting of the New York State Medical Association, held in Brooklyn,, May 28, 1895.

zation has been promulgated. The most constant evidence of local injury to the cortical substance of the brain with such aphasic symptoms as pointed to local compression, was where there were distinct marks of inward displacement of fractured bone over the fissure of Rolando or the middle parietal convolutions.

My general line of practice, in cases of fracture through any area of the cranial vault attended with a moderate indentation of bone but no cerebral symptoms, is to not interfere with a view of elevation or displacement. This line is especially adhered to when the seat of displacement is over any of the large sinuses.

Cocaine as an Analgesic.—In the operative technique for elevating shattered and displaced fragments of late we have substituted pulmonary anesthetics altogether, by employing local cocaine analgesia. This change has been most advantageous to the operator, in lessening hæmorrhage by the well-known hæmostatic action of the medicament, and obviating the necessity of so many trained assistants as would be otherwise rendered nececessary.

The difference of the effects consequent on the utilization of this line of treatment is vastly in our patient's favor, as by it there is no such engorgement of the cerebral vessels as we always observe under ether; as no cerebral excitation at a period when it is obvious that violent commotion of the cerebral centres must be harmful to our patient; and persistent vomiting after operation is entirely obviated.

Debridement instead of the trephine.—Except in rare instances the trephine has been entirely displaced with me by the osteotome for elevating and removing depressed bone fragments in skull injuries. By its cautious employment there is much less danger of damage to the dura-mater, the brain substances, or the cranial sinuses; and less bone may be sacrificed. For simplicity, safety and readiness of employment it is a great improvement on the trephine in this class of cases.

Asepsis and refrigerants as prophylactics.—Experience has long since taught me that, except for the scalp tissues, all chemical solutions should be rigorously eschewed in all skull fractures involving an operation. My early experience soon taught me that any description of antiseptics when applied to the rude elements of bone anywhere, and to the dura-mater and cerebral tissue in particular, are full of danger to the vitality of the protoplasmic elements and may be promptly followed by grave inflammatory changes. Now, in my service, nothing is ever employed for flushing or cleansing in cranio-cephalic operations except sterilized water.

The ice-cap or iced-cloths are immediately applied to the whole exposed wall of the skull, and are continued until reaction is fully established.

It is my conviction that moist cold over a traumatized surface, is a potent prophylactic against consecutive inflammation, cellulitis or meningitis in all skull injuries, and should be always employed until about the third day, when it may be discontinued.

Mercury in meningitis.—Mercury judiciously administered is an agent of unrivalled excellence, in inflammatory conditions of the fibro-serous membranes. On the meninges, it acts with especial energy; therefore, in cases of cranial trauma, a purgative dose of calomel is given early, and repeated later, should symptoms of meningeal trouble threaten; the dose of the drug being so proportioned as to promptly secure its full therapeutic effect without its possible lethal action.

FRACTURES OF THE LIMBS.

Fractures of the extremities, we are almost never without in the Harlem Hospital service. In my own private hospital notes on this interesting and current type of truama, there are more than two thousand cases enumerated, though more than four thousand cases have come under my notice in the past twelve years. Since March first, this year, we have had entered of fractures of the extremities, ninety-one cases—seventy-six simple; and fifteen compound.

In the deluge of surgical literature spread before the medical profession since the doctine of antiseptics was established, it is singular to note that, except in the treatment of the compound variety, little has been presented on fractures of the extremities. In fact this study has been allowed to lapse. There is, however, no class of surgical injuries of greater interest than those fractures which involve the structures on which we depend for locomotion and prehension. Their correct treatment will reward us with a fair degree of restoration of contour and function; while when managed on wrong prin-

ciples, diminished power and motion are quite certain to follow.

The number here considered includes fractures of the clavicle, arm, forearm, leg, femur, and bones of the hand and foot.

Muscular relaxation rather than forced extension.—The guiding principles which we observe in small fractures, are, first to secure muscular relaxation and osseous reposition, without employing violence. Forced extension or counter-extension in certain fractures, are not wanting in theoretic support; but in fracture, a considerable experience, with careful observations, has convinced me that continued tension on a limb rather provokes muscular rigidity than effects relaxation. Besides, the co-existing pressure on the main blood-trunks and the tendency to sloughs in enforced confinements to bed, are among the drawbacks of steadily maintained tension. The rules of physics will not apply to fractured bones, otherwise such a thing as deformity after treatment would be impossible, except in the event of great loss of bone.

Muscular relaxation with support to the mangled tissue favors the falling of the fragments into their natural position. There they will remain, and restoration of contour will be the rule in many bones; but with the clavicle and humerus the incessant respiratory movement, and in the femur the demands of nature and the necessity of frequently shifting the body are disturbing influences which nothing can entirely overcome, and hence some sort of support is necessary.

Support of the fragments rather than fixation with gypsum.—When the plaster of Paris mould was first introduced it was at once seized on as the ideal material for fracture adjustment. It does serve most purposes when employed in appropriate cases; but everything is buried under it, and its removal is always attended with jarring of the limb. For a long time it has been my custom to employ it, never as a primary dressing, but after the provisional callus is formed, it answers a useful purpose.

In the treatment of compound fractures our first endeavor is to securely replace the fragments and close the wound—make the fracture a simple one.

In compound comminuted fractures, with immediate, partial or complete asphyxia or destruction of the tissues, our aim is to first suppress all hæmorrhage by closing separately the large bleeding vessels, thoroughly cleansing and dressing the wound, and placing the parts under covering in a comfortable position.

Little toe. Traumatic amputation.

PRIMARY AMPUTATIONS.

Primary amputation after disorganization of a limb, in civil life, is always a questionable procedure; though, when a limb has been practically traumatically amputated, we may, at once, with the scissors divide the frayed integument or tendons.

There have been in my service lately, eight amputations for traumatism and pathological conditions. After reaction, when the line of demarkation is formed in traumatic cases, we run little risk of a sloughing flap. Such a case is now under my care; a young man had his foot crushed off at the ankle joint, by a railroad accident. Four days later, after the line dividing the healthy from the dead tissue appeared, sufficient of the parts under the healthy skin were cut away to allow the healthy integument to fall in over the ends of the bones and cover them without strain.

CERVICAL TUMORS.

Ten cases of serious submaxillary cervical tumors have come under my care within the past three months.

One, a case of sarcoma of large size in an old man of sixty-four, was refused operation. It was not, apparently, deeply lodged; but as there were rapidly developing new growths in the hard-palate, pharynx and spheno-palatine fossa, it was decided that an operation was not warranted.

One tumor of large size was a lipoma, this sprang from the loose subscripital tissues and advanced forward and downward to dip under the posterior of the sterno-mastoid muscle.

Importance of accurate diagnosis.—One man on whom we operated, had a voluminous growth which occupied the whole quadrangle of the neck; on right side advancing up under the lower jaw, and downward behind the left clavicle, to and through the apex of the pleural cavity. He had been operated on four months previously; the growth reappearing consecutively, rapidly enlarging, and now, so far forward under the deep cervical fascia as to encroach on the tracheal rings and threaten suffocation.

At the institution in which he was first treated, radical operation was refused as the growth was declared malignant. The mass was hard, unyielding and painful, with deep attachments. After careful and thorough examination of his case, it was my conclusion that the mass was wholly tubercular, and that, while its removal would demand a very formidable operation, it was clearly within the range of operative surgery to turn it out safely. It was presumed that in the first operation the superficial absorbents were removed, and that the regrowth consisted in a hyperplasia with central degeneration of the deep chain, which lies in close contact with structures vital to life.

Hæmorrhage in operations on voluminous cervical tumors for their removal.—The most formidable danger in the complete removal of cervical neoplasms, comes from hæmorrhage; and there is nothing that so severely tries one's courage and skill as the occurrence of it in this class of cases. Celerity and coolness must be combined when an arterial spring is opened, or the operative field is suddenly flooded by the vascular torrent. In infilirating, malignant growths of the neck, removal always entails great danger because of a steady oozing which cannot always be wholly staunched before dangerous anæmia sets in.

In the above mentioned case, the operation of enucleation was commenced by dividing all the overlying structures in the centre, a cervical incision having extended across the entire mass. Great care was taken to clamp and ligate all the bleeding vessels as we preceded. The peripheral decortication was comparatively simple; but, as we penetrated into deep parts, difficulties began to appear.

Early in the operation the internal jugular vein was divided and both ends ligated. Next, as we proceeded more deeply to turn the growth out, consecutively, the cervicalis ascendens, the ascending thyroid, the transversalis coli, and the occipital arteries were clamped, ligated and divided. Of the nerves, the descendens noni, phrenic, and the anterior cervical branches of the cervical plexus were divided and their ends teased away from the elements of the tumor. The common carotid was adherent by its sheath from the clavicle up to the point of bifurcation. The sheath with the pulsating vessel was cautiously detached from the under surface of the growth, and now, while endeavoring to enucleate the deep supra clavicular lymphatics and press forward the subclavian artery, the pleural

cavity was opened just below where the subclavian arches upwards. Now the whole mass was lifted out, leaving a large chasm, exposing the tracheal plexus, the large blood-trunks and the trachea. The opened pleura was then closed, the bleeding subsided, and the edges of the integument were brought together.

In this case, although there was an extensive mutilation of tissue, but little blood had been lost. Our patient rallied well from the operation. His recovery was prompt; the line of incision closing by primary union, except at the part left for drainage. But little blood had been lost, and no shock followed.

The mass proved to consist of an aggregation of tubercular glands; some simply hypertrophied, others were suppurating and caseous; all were bound together by dense inelastic matting of fibro-connective tissue. Although the thyroid, submaxillary and sublingual glands were freely exposed, no trace of infiltration was visible.

Of the other seven cases two were malignant; two were acute supphrative inflammation of the lymphatics; of the remaining three two evidently were tubercular but not suppurating. These are being treated by palliative measures.

HERNIA—VARIOUS TYPES.

Sixteen cases of various types of hernia have come under my notice since the beginning of the present term—these included strangulated, incarcerated, reducible and irreducible cases. But one case required operation for strangulation. The operation was performed late at night, by a member of the House Staff.

Deaths in strangulation attributable to delay and to avoidable errors in operating.

This case, which terminated fatally, was most fruitful in suggestion and in pointing the way to avoid mistakes in treatment.

The case was neglected in the beginning, by the practitioner who was first called by persisting in violent taxis, and allowing his patient to suffer until collapse set in before sending for or calling in active surgical relief.

The next oversight was committed in the details of operation. A knuckle of intestine was partly twisted on itself; a patch of gangrene about the size of a quarter, extending through the glandular and muscular tunics, occupied the walls of the bowels—though there was no perforation, as the outer fibro-cellular coat was intact. Vomiting ceased after the constriction was relieved and the intestine returned, but the man did not react and sank thirty hours after operation. On autopsy, it was found that a fatal error had been committed in the management of the extruded coil. The adhesion which held the coiled bent surfaces of the intestine together, had not been liberated and, in consequence, its lumen remaining completely obstructed, internal strangulation followed, thus removing every possible hope of recovery. The gangrenous area, in my opinion, was not enough to seriously call for resection, the use of the Murphy anastomotic button or other adjustment, inasmuch as it is extended only about half way over the entire cylinder and would undoubtedly have taken care of itself by making an adhesion to some of the neighboring viscera, thereby preventing any possible leakage.

Critical inspection of the protruding mass and thorough liberation of all constrictions, both within the sac, the canal and at the internal ring, indispensable in all cases of operation for strangulation.—In all cases of operation for strangulation, after we have freely divided the points of stenotic impediment, it is of the greatest importance that we critically inspect the conditions of the ectopic viscera and completely liberate the imprisoned structures. A failure to do this renders an otherwise life-saving operation, inert in its effects. A practical demonstration of this came under my notice recently. A man was seized with symptoms of strangulation after stool. He had a chronic incarcerated inguinal epiplocele. An incision was made down in the upper surface of the mass, the omentum exposed and the inner ring divided. But there was no relief of the symptoms after operation and the patient sank unrelieved the following day. On autopsy a loop of intestine was found caught, crushed under and concealed by the omentum. This had entirely escaped detection and continued occluded after the epiplocele was exposed.

Treatment of reducible hernia.—Nine cases of reducible inguinal hernia have been examined by me, within the past ten weeks. My practice in this class of cases, is not to advise operation unless the hernia is progressively enlarging, is painful,

threatens strangulation, is not trussable, or the patient is desirous of relief from the deformity. Besides the class enumerated, it is my custom to recommend a radical cure in a female, or in those individuals whose deformity constitutes an impediment to entrance into the civil or military service. But one of these nine which came to me was regarded as appropriate for radical cure. He was a young man who had hernia since childhood. It was of the indirect inguinal type. This was operated on with gratifying results, the patient leaving the hospital in two weeks.

O'Hara's or the Australian operation the the best for open treatment.—Of the almost infinite number of operations recommended during the past ten years for cure of hernia, there is none which in so large a measure fulfills the requirements with so little mutilation, as the operation devised by Mr. Henry M. O'Hara of Melborne, Australia. Briefly described, it consists in an isolation of the neck of the sac, its division and retraction up through the canal and internal ring to the fascia transversalis, where it is anchored by absorbable suture material. It entalis no weakening of the abdominal walls by divisions of the aponeurosis, no divisions of large vessels, there is no drainage required, and no disfiguring scars left. In fifteen cases so treated by me since April, 1894, there have been no relapses.

ABDOMINAL SURGERY.

Without doubt in the whole field of medical science and since its earliest dawn, there has never been anything to equal the stupendous progress made in *abdominal and pelvic* surgery during the past twenty years, and in this, let medical history record it, America has occupied the position of the pioneer. In 1881 the celebrated Simms gave to the professional world his conceptions on the possibilities of surgery in this direction, though unhappily he did not survive to realize the fruition of his hopes. Bigelow had perfected lithol·osity. At the International Medical Congress in Washington, in 1886, Nicholas Senn presented his thesis on the surgery of the intestine, and startled the rank and file of the profession by the immensity of his original and marvellous researches and experimentation on abdominal surgery in the lower animal, and his lucid demonstration of their application on man. Abbe had been a generous contributor in this line, and posterity is indebted to Sands for opening the way to that operation on the appendix, since perfected by McBurney, and through which thousands of lives have been saved. It has rendered necessary the re-writing of the pathology of the peritoneum. As would seem the climax of all, the young Chicago surgeon, Murphy, has invented an anastomotic button, the very acme of human ingenuity, which has rendered the surgery of the intestine more expedient and safer than ever.

Timeliness and skill in operations on the appendix.—During one week, from April 5 to 13, in this year, seven cases of severe abdominal disease came under my notice. Six were of appendicitis; four were of the perforating type. Two came into the hospital in the advanced stages, too late for relief by operation, and both died within twenty-four hours after entrance. Two were operated on; with perforation of the appendix in both cases. In one there was a double perforation with general peritonitis. Both recovered. Two mild cases of the recurrent type were treated by palliative measures and recovered. In one abdominal case which was brought into the hospital, great prostration was present. My colleague, Dr. A. Palmer Dudley was of the opinion that there was mechanical obstruction, though it was my impression that it was the appendix which was at fault, and that obstruction was due to intestinal paresis. The abdomen was so extremely tympanitic that it was impossible to definitely locate the structures. On section the appendix was found healthy and, as Dr. Dudley had predicted, the small intestine was found obstructed by a band at about its center. The patient rapidly sank under ether, before the incision could be closed.

It was formerly my conviction that, as the danger in the operation itself seemed to me very great and the larger part of those cases of appendicitis do well under medical treatment alone, surgical interference was not proper in any except rare instances. Later experience has convinced me that this position is not tenable and that in all cases of appendicitis which show a tendency to persistently recur, or or are of the acute fulminant type, the correct course is prompt operation. The

results in operation depend almost entirely on operating just at the right time and performing the operation with skill and celerity. The time to operate is, and always probable will be, very difficult to determine. Its performance, for a successful issue in a large number, requires special skill and experience. A small incision, the quick ferreting out of the appendix under the trained finger, the neat and aseptic amputation of it, without unnecessary loss of time or trauma of the peritoneum count vastly in the patient's favor.

On the 28th of April Dr. J. A. Hoffheimer called me in consultation to see a case of appendicitis under his charge with the view of determining the propriety of an operation.

The patient was a boy of twelve, who had had previous attacks. It was the sixth day of his illness, when I saw the case. At this time, his pulse was 143 per minute; the temperature 103°; there was some vomiting, and severe pain when morphine was not pressed. The abdomen was extremely tympanitic, and over the appendix sensation to pain on pressure was extremely acute, though all the abdominal areas were hyperæsthetic.

After a careful examination of the case, giving due weight to the various serious symptoms present, the lad's grave condition, and the uncertainty of results after radical measures, when the advanced stage of the disease is reached, my opinion was that nothing definitely could be promised by operation, and it was possible that recovery might ensue by energetical constitutional measures. Three days later the boy died just at a time when it seemed that peritoneal inflammation had subsided. Now my regret is that I did not operate. Indeed, there can be scarcely a question but in all these cases, no matter what the stages of inflammation may be, when we are once assured that the appendix is the actual seat of serious disease, an immediate operation should be invariably insisted on.

JOINT DISEASES.

The influence of systemic cachexia on the arthopathies which succeed injuries.—Several cases illustrating the various phases of joint *injuries* and *diseases* have lately come into the hospital for treatment. The dominating patholigical changes attending these were rheumatism and tuberculosis. There can be scarcely a doubt but various constitutional disturbances impress their stamp on many traumatisms and enhance the vulnerability of various organs and structures. This is especially true of the tissues which enter into the joints.

The articular heads of the bones are the center of great activity during the processes of growth and development. As a move in the direction of arriving at an accurate knowledge of the precise pathological conditions which obtain in certain arthritic elements, it would be well if the terms "hip-joint disease" or "knee-joint disease" were abolished.

A young man, late in the autumn of 1894, sustained a sprain of the knee, in a foot ball game. He was treated at home and elsewhere for "knee-joint disease." Failing to secure relief from the various fixation appliances which had been employed, he entered Harlem Hospital on the 12th of March. On a critical examination of the joint there was no evidence of any morbid changes in the capsules or cartilages; but the head of his tibia was enlarged and exquisitively sensitive. The cancellous center of this bone was opened freely; the trephine entering just under the insertion of the tendon of the sartorious. A pus cavity was tapped and a considerable residue of necrosed bone curetted out. All pain immediately ceased, the spasmodic contraction of the hamstrings passed off. He returned within four weeks to his trade of a painter when his "knee-joint disease" (?) was cured.

A young man entered later, who a few days before had violently wrenched his knee. He was sent in to have the supposed hæmorrhagic distension of the capsule relieved by evacuatien through an arthotomy.

It was found to consist entirely of a hæmatoma into the loose cellular tissue outside the aponeurotic investment of the knee joint, and wholly disappeared by a few days' rest with moderate bandage pressure.

A young woman of good physique was sent into the hospital for the treatment of "acute suppurative synovitis of the right knee joint." On inspection it was found that the patella was displaced inward and deeply lodged under the projecting surface coming down from above. The case

was clearly one of acute phlegmon under the fascia-lata, its fluid contents being arrested from advancing further downward by the insertion of its fibrous hood into the lateral surfaces of the quadriceps tendon. The articulation had wholly escaped. An incision, evacuation and drainage gave immediate relief, and final recovery was rapid.

Rheumatic pain sometimes antecedent to trauma of the joints.—Rheumatic affections of the joints of the lower extremities are sometimes preceded by a weakening of the muscles. This precedes the intense pain and swelling. The person about to be seized is conscious of a sense of lameness or unsteadiness in the articulation. He is now liable to a fall or a wrench, when, all of a sudden, all the typical symptoms of acute inflammatiou set in, and he has a pan-arthritis. To mistake this mixed condition for a joint trauma alone, and concentrate all one's attention on the local trouble, may lead to serious results. Protracted fixation of a limb always interferes with its full nutrition and arrests its growth in growing children.

Several cases have been seen by me during the spring months, supposed to be organic disease of the joints which promptly recovered when all retaining supports were removed, the joints allowed full liberty and rheumatic remedies pressed.

Resection of diseased joints or conservative methods.—Formal resection of a joint is never done in my service unless there is evidence that disease has completely disorganized it. In those cases it remains a question if an amputation is not preferable. Resection of a joint, let it be remembered, means its entire destruction. In the child, under ordinary surroundings, after a time tubercular disease of the heads of bone often tends to spontaneous arrest. My practice in aggravated cases of this type is to open and curette the joint, preserving the ligament and cartilages. In adult tuberculosis of bone, reaction will not arrest the progress of the malady which is now, usually generalized and progressive.

MAMMARY TUMORS.

Among the cases seen and treated by me within the past quarter, were five cases of tumor of the mammary gland. Three of them were malignant, of the epithelial variety, one recurrent. Of the other two, one was a dermoid cyst and the other tubercular.

The therapy of malignant mammary neoplasms—The cyst was readily decorticated, the incision promptly healing. Seven years before she had the opposite breast removed for the same condition, in which up to the present time there had been no recurrence. An incision, curettage and drainage cleared away the strumous infiltrate.

The principles which should govern us in the management of cancer of the breast are still *sub judice*; indefinite and unsettled, although the reports coming in from the results of the extirpation of all the axilliary absorbents with the complete removal of the mammary glands, point to a great improvement of this method above all others.

One of these cases was treated by me on this plan for the reason that there was already an immense secondary growth in the axilla. In her case, there was a large, hard infiltrating, secondary growth in the axillary hollow, which required a very delicate dissection to remove it without damage to the main arterial trunk, to which the tumor maintained a firm grip.

The long thoracic artery with the thoracic alaris were divided and the axillary vein opened. But, all hemorrhage was readily subdued. The patient ultimately made a good recovery, though with marked limitation of shoulder action, in consequence of the cicatricial contraction in the apex of the axillary space. The direction of dissemination is always centripetal along the course of the absorbent vessels. The adenomatous structures of the lymphatics, serve as out posts to prevent systemic infection, and no doubt are invaded at an early date. The complete operation is one which entails an extensive multilation of tissue and is, perhaps, more dangerous to life than simple mammary excision; but the promise which it gives us against relapse more than outweighs these objections.

One patient with a small, hard scirrhus refused operation and later I was informed went into the hands of a charlatan.

A case of recurrent cancer had been first operated on by me in November, 1884, and again six months later. She had refused any further cutting operation.

In her case the powerful chemical cauteries have been employed by me, with the

hope of being able to clear away the fungating crop of pulpy granulations which occupied the site of the scar tissue. It succeeded fairly well, at first, but its repetition, in an attempt to destroy the substrata of neoplastic elements, was attended by such agonizing pain and positive shock that life was endangered and my patient declared she would rather die than undergo the ordeal again.

When arsenical paste was employed, although its activity in charring the tissues was decided, yet there were invariably symptoms of constitutional poisoning; numbness of the extremities, from toxic neuritis, nephritic irritation, sore throat, and very severe gastric symptoms, followed in every instance.

My own unsatisfactory experience with caustics has led me to employ them in malignant growths with caution, and never except on those which occupy the periphery and are of a very limited area. In labial epithelioma or on senile growth involving the nose or eyelids, the caustic substance will serve a most useful purpose.

SPINAL IRRITATION.

W. H. WALLING, M.D., PHILADELPHIA, PA.

Spinal irritation is generally characterized by tender spots along the spine, more or less pain in the back and down the limbs, with weakness in the limbs, this latter being in some cases very pronounced. Pain is frequently felt in the stomach, and the patient may seek advice for some supposed malady in that organ, being unaware of its spinal origin.

The painful or tender points along the spine in many cases are very easily found upon pressure, but in others the trouble is obscure, and the difficulty is only located upon electrical examination. The technique of such procedure is as follows: The patient removes the outer clothing except from the lower limbs; is covered with a sheet, if a female, and then seated upon a wet sponge or pad, connected with the positive pole of a faradic battery. The operator, with the negative sponge, using a current of just sufficient intensity to be plainly felt, commences at the nape of the neck and passes slowly down upon each side of the spine, carefully noting the sensations produced. Over the tender points, pain will be felt. This will frequently be found to extend across the whole lumbar region, sometimes involving the sciatic nerves. It must in some cases extend around the sides from the lower cervical and the upper dorsal portion, more often upon the left. Again it will appear only at or near the median line. This accounts for the pain in the region of the stomach, above referred to.

In males, I find the difficulty mostly confined to the lumbar region, and such cases are sexually impotent, as a rule.

The cause of the disease is sometimes obscure. Many cases that have come under my observation have resulted from an attack of the grippe. Others were due to over-exertion, or prolonged standing, as in shop girls. Others to the jar of the street cars, combined with long standing, as in conductors and motormen, or gripmen. Some are traceable to traumatism; still others possibly to some specific taint.

In some patients the tendon reflex is abolished, in others I have found it exaggerated. In the former class, strychnia agreed with the patients; in the latter, it aggravated the symptoms in some cases.

The treatment consists in removing the cause if possible; rest, counter-irritation, electricity, and proper medication. As a counter-irritant tincture of iodine and glycerine, equal parts, makes a good application. Paint on thoroughly for fully ten minutes. If tincture of iodine be used ullfstrength, as may be necessary in some cases, it too should be applied freely, and then allow the skin to heal before applying again.

Proper electrical treatment is very valuable, and in order to give such treatment, a good battery and intelligent application must be combined. I use a Kidder faradic, and for the most soothing effect, the whole coil, *i. e.*, the current selector rests upon the "A" and "E" posts, with the tin

tube covering the coil, completely removed, the current being governed by a controller. The technique is as follows: Seat the patient as for diagnosis, with the negative pad on the stool, then with the anode, or positive pad, at the nape of the neck, turn on just sufficient current to be plainly felt, and pass gently down the spine, resting for several minutes over each tender point. A large pad is sometimes preferable for use on the spine, especially if there be much tenderness, as more current can be thus used. Pass up and down the spine and around the sides, for twenty minutes to half an hour, repeating daily or every other day, as may be needed. We get better effect by using the uncovered coil, as above directed, than if only part of it is in the circuit.

In many of these cases the brain is involved and must receive attention. At the close of the sitting, change to the galvanic battery. The patient may complain of being dizzy at times. If this be from plethora, place the cathode on the left temple and the anode back of the right ear. Turn on one or two m.a. of current, hold the pads as adjusted for one or two minutes, then carefully move cathode to the right temple and the anode to back of the left ear, continue as before, and finally bring the cathode to back of the contact with the skin. Now increase the right ear without at any time breaking current to three or more m.a. if the patient can bear it, and use this for two or three minutes. If at any time during the sitting, the patient should complain of being dizzy, reduce the current to a pleasant tolerance. Always turn the current on and off very gently.

When there is an anemic condition of the brain, proceed in the same manner but with the poles *reversed*.

Medication.—This will include, of course, diet and hygiene, as well as drugs. The first two must be regulated according to the case. As to medicine, I have had the best results from the use of the tri-bromide of gold, and the oxy-bromide of arsenic.

If the trouble is of specific origin I use the combination of the tri-bromide of gold, with the oxy-bromides of arsenic and mercury. This latter preparation is a specific for all conditions arising from syphilis.

Gold and arsenic are powerful alteratives and reconstructives. They have a most wonderful effect in all sclerotic conditions, promote healthy metabolism, and prevent decay. I now have on hand two cases of chronic spinal irritation, which are rapidly yielding to the gold and arsenic treatment.

This combination also acts as an aphrodisiac, giving in many cases most satisfactory results. For further information regarding the tri and oxy-bromids, the reader is referred to an article by the writer in THE MEDICAL AND SURGICAL REPORTER, January 26, 1895. I shall cheerfully answer inquiries from any reader of the REPORTER regarding these remedies.

Restoring Persons Apparently Dead from Chloroform.

Leedham-Green (*Birminghan Medical Review*) calls attention to the König-Mass system of rapid compression of the precordium as used in Göttingen. The case on which he tried it was a child four months old. The operation of circumcision had nearly been completed when the child became deadly pale, the pupils dilated, and the respiration and the heart's action ceased.

The child was apparently dead. The surface became pale and cold, the eyes shrunken, pupils widely dilated, and there was a collection of froth at the mouth. Rapid compression (about 120 per minute) of the precordium was followed by a faint gasp and ultimate recovery. Seven minutes had elapsed during which neither heart-beat nor respiratory effort could be detected. Sylvester's method which was first used, was totally inadequate.

Laparotomy for Perforation in Typhoid Fever.

Parkin (*British Medical Journal*) gives the history of a case in which the perforation was promptly diagnosed and operated on only two hours after it had occurred. The patient died three days after the operation. The author states that this added one more to the list of twenty such cases which had been so treated with only one recovery. There is no doubt that perforation in the course of enteric fever is almost invariably fatal, and any recovery from such a complication can only be regarded in the light of an accident unless surgicial treatment be adopted.

THE MANAGEMENT OF THE NEW-BORN.*

T. H. MARABLE, M.D., CLARKSVILLE, TENN.

My subject deals with the infant from its first arrival into this world of care, whether it greets you in that boisterous way which is familiar to every practitioner, accompanied by the subdued words of the mother, "Thank the Lord!" or whether it comes silently into existence. After having satisfied myself as to the viability of the child, I tie the cord in two places; first about three-forths of an inch from the child, and, leaving a few inches interspace, I again ligate. Having severed the cord between the two ligatures, the child is laid in a warmed flannel, wrapped up and put aside.

If it be still-born, or a weak, delicate, poorly-nourished child, I, by stripping between my fingers, force the blood from the cord into the child and tie; if cyanotic, I allow the cord to bleed before tying. I have frequently resuscitated in this way. If these methods fail, I resort to shock by plunging first in hot, then cold water. If this does not resuscitate, I allow the child to remain for ten minutes in the hot bath and use Sylvester's method, allowing the neck to rest on the rim of the bowl, using my foot as a head rest and to prevent the head from falling back too far. This extends the neck and the head is thrown back. Then with the Sylvester method of inflating and expelling air into and from the lungs, I continue my resuscitating process. If after continuing in this position for ten or twenty minutes, the child does not breathe or cry, I plunge it into the cold bath and continue as before, but I do not allow the child to stay in the cold water more than five or six minutes. I continue alternating as above for two hours, if the child does not resuscitate. I have not infrequently continued this method of resuscitation for an hour and a half before being rewarded with a cry

Having gotten the child to cry and breathe regularly, I wrap it in warm flannel and lay it away for some hours if very feeble.

Washing and dressing the child I always delegate to some female, but have it done under my supervision. I have some clean warm water gotten; then having had the child anointed thoroughly with vaseline, sweet oil, or more commonly lard, to facilitate the removal of the vernix caseosa, I have the nurse proceed to wash it, using as an applicator a sponge or soft cotton cloth, using, preferably, castille soap in the water. Care is taken to clean the folds and joint flexures. If, as is occasionally the case, the vernix caseosa can not be removed without too tedious handling or if the child is feeble, I have it wiped dry and again anointed. I find it can be cleaned very easily at the next bathing.

The child being now ready to clothe, I dress the cord in the following manner: The stump, being from three-fourths to one inch long and tied as I invariably do it, I turn up on the abdomen after having wrapped it in absorbent cotton. I fasten it in this position with a piece of surgeon's plaster one inch wide by six inches long, which I place across the abdomen to hold the navel stump in place. I allow this to remain for four or five days, when, with a folded piece of cloth previously wet in warm water and laid on the plaster for ten or twenty minutes, the plaster can be easily removed. I prefer this method of dressing the navel to the bandage with linen and grease, so frequently used, for the following reasons: The dry dressing tends to mummify the cord and there is seldom any odor during the dropping off of the cord; the plaster does not slip nor need constant attention as does the bandage; it is more easily put on, it is more cleanly, and the child is less liable to take cold on removing it.

Having finished dressing the child, it is immediately put to the breast. This is done as a safe-guard to the mother. Should the secretions found in the breast at this time be not sufficient to satisfy the child, I do *not* allow the nurse to give it a sugar-teat or fat meat, having noticed long since in my practice that this produced what is commonly known as "three months colic,"

*Read before the Tennessee State Medical Society, April, 1895.

which is nothing more or less than dyspepsia. My parting injunction to the nurse is, "Do not give the baby a sugar-teat nor fat meat." In case the child is not quiet and does not sleep as is usual, I instruct the nurse to give catnip tea with a small amount of whiskey in it. I have found from experience that this will satisfy the hunger and cause the kidneys and bowels to act. It is also a very fine antispasmodic. This is kept up from three to six days, at which time the mother's milk usually appears. Should the mother not give sufficient milk, or fail entirely, as is sometimes the case, or if I have what is to me the most inhuman of all human beings, the fashionable mother who does not want to nurse her own child because "she has not the time to stay with it, and besides it makes her grow old faster if she nurses it;" (such a mother should not be tolerated in good society, for there is nothing that suits the baby like the mother's milk), experience has taught me there is no one kind of food you can give these unfortunate babies—for they are unfortunate, either from a perversion of nature or perversion of motherly instinct, they never know a mother's love. The next best substitute is the wet nurse, provided you can get a healthy one and the ages of the children are nearly the same. This not being an easy matter, I usually first try cow's milk fixed in the following manner: Cow's milk one part, water (previously boiled) three parts, to which is added a small amount of sugar of milk, and one-half teaspoonful of lime water to the ounce of milk diluted as above. I feed this to the child, an ounce every two hours, gradually increasing until by the end of the first month the child is taking two ounces and the intervals of feeding have been increased to two and a-half or three hours. The amount of milk is now increased, each month an ounce, up to the sixth month, and the intervals lengthened to four hours. If warm weather, the child is bathed in tepid water daily, the clothing is light and loose fitting. I do not allow any tight bands; they interfere with the circulation and respiration of the child.

But with all care for minor details, I have not infrequently had to change the food a number of times before finding a food suitable for the child. I recall a case which came under my care last summer. I tried everything, cow's milk, goat's milk, sterilized milk, condensed milk, Horlic's malted milk, Nestles food, Imperial Granum, and, lastly, I put the child on Mellin's food, when it began improving and continued to do so until it was in perfect health in about six weeks. The mother put him back on sterilized milk, saying she had the cow and the sterilizing outfit. From this time the child was continued on sterilized milk, though occasionally it would disagree with him. Then the mother, under my direction, would return to the Mellin's food and the digestion would again right itself. Other cases have come under my care in which I did not get any benefit from the use of Mellin's food. In fact I have most frequently gotten benefit from the condensed milk. I use Reed & Carnrick's brand; have found it agrees better than the brands ordinarily sold at the grocery; being put up for infant feeding, the milk is better selected and the cows from which the milk is taken are more carefully looked after in their water supply and food.

An important principle in the clothing of infants is to apply the garments so loosely that while they protect from the cold and secure the necessary warmth, they do not restrain the functional activity of the organs underneath. This was my chief reason for quitting the use of the belly band; the irregularity with which it is put on by the nurse, the changing it each day, or whenever it became soiled, and after a few weeks or months it is generally left off, endangering the child with cold.

I never use the nursing bottle with rubber and glass tube attachment, on account of the difficulty in keeping them clean and sweet. I use the plain rubber nipple, and when once used I direct the nurse to turn it inside out and put it in soda water. The bottle is also thoroughly cleaned and aired before using a second time. If these rules are followed strictly, my word for it, there will be a great deal less suffering among the artificially fed or bottle-raised babies.

A recent London *Lancet* has interesting allusions to the "successful use of electricity in trigeminal neuralgia and to long-continued treatment of tic douloureux (which is practically the same thing), with long and short applications of the current. Success is uniform in all cases."

THE DAMAGE SUIT.*

DUNCAN EVE, A.M., M.D., NASHVILLE, TENN.

The duty has been assigned me of preparing a paper on "The Damage Suit." It seems, therefore, indispensably necessary that the subject should be defined. You will be surprised to find that neither medical nor legal dictionaries attempt a formal definition of malpractice. I must, therefore, content myself with quoting a well-known authority on medical jurisprudence, which defines medical malpractice to be: "The unskillful or negligent treatment of a patient by a physician or surgeon, or some one undertaking to act as such, resulting in an injury to the patient."

Hence it will be seen that in order to maintain a suit for malpractice two things must appear, viz.: Unskillfulness or negligence in the treatment of the patient, and the injury to the patient.

The question therefore arises, how much skill is required? The answer to this is, ordinary skill; and ordinary skill is defined to be such skill as is usually possessed by members of the profession at the time and place when and where the individual is practicing. Extraordinary skill is not required unless the party expressly contracts for such a degree of skill. The law allows such a contract and will hold the party to it, if made. But the "code of ethics" forbids such contracts.

The impression seems to prevail that a physician or surgeon is held to a higher degree of skill than members of other vocations. Such is not the case. No doubt this erroneous impression frequently causes suits for malpractice to be instituted, and the sooner this impression is removed the better. The degree of diligence is simply such care and attention as the nature of the case demands. In illustration of this fact, Elwell states that the degree of care and attention which would be required in a case of iritis is very different from what would be necessary in a case of chronic rheumatism.

When a doctor is sued and charged with unskillfulness he has the right to prove that he is a graduate from a reputable medical school, and also to prove his reputation for skill by his professional brethren. He also has the right to prove his treatment of the patient in the case being tried, and ask the opinion of members of the profession as to what degree it was skillful or otherwise; to show the care and attention given the patient, and to take the opinion of the members of the profession as to whether the same was reasonable or not.

A physician or surgeon is not to be judged by the result. He is not an insurer, and is only held to exercise reasonable skill, care and attention in the treatment of his patient. In case of doubt as to which would be the better treatment or operation or dressing, etc., he is simply required to use his best judgment.

The patient is required to co-operate with the attending physician or surgeon, and to follow his directions, and if he fails to do so, the physician or surgeon is not to be held responsible for the injuries resulting from such failure, whether the same be from disinclination or the pain of the patient. In either event it is the misfortune of the patient and not the fault of the doctor.

From a well-known medico-legal work we find the following rules have been thoroughly established:

1. A physician or surgeon, without a special contract for that purpose, is never considered as warranting a cure.

2. His contract, as implied in law, is: (*a.*) He must possess a reasonable degree of learning, skill and experience, which is ordinarily possessed by others around him, in his profession. (*b.*) That he will use reasonable and ordinary care and diligence in the treatment of the case committed to him. (*c.*) That he will use his best judgment in all cases of doubt as to the best course of treatment.

3. He is not responsible for want of success, unless it is proved to result from want of ordinary skill, or from want of ordinary care and attention.

* Read before the Tennessee State Medical Society, April, 1895.

4. He is not presumed to engage for extraordinary skill, or for extraordinary care and attention.

5. He is not responsible for errors of judgment, or mere mistakes in matters of doubt and uncertainty.

You will doubtless infer that I have some familiarity with questions arising in suits for malpractice, and I admit that I have had experience on the subject. I have been sued several times and yet never compromised or lost a single case.

Elwell declares that nine-tenths of all the cases of malpractice that are brought before the courts for adjudication, arise either from amputations, fractures or dislocations.

This is from the fact that members of the legal profession fail to acquaint themselves with the difficulties and even probabilities which the surgeon must encounter. They do not know that in many fractures and dislocations, shortening and deformity are the rule.

Professor Austin Flint, Sr., abandoned the practice of surgery and confined himself exclusively to the practice of medicine because of the danger arising from damage suits. It does really seem that the safest course for a surgeon to pursue—not knowing what a jury might do—is to make over his property to his family.

One cause of suits against the members of our profession is the enmity, jealousy and rivalry that unfortunately exists among them. Too often is it the case, that a doctor is the one, that in some way, is responsible for the litigation.

Our profession is justly distinguished for its charity, and the gratuitous service it renders the poor, yet strange as it may appear, more suits are brought by pauper patients for damages for alleged malpractice than all other classes combined; and, according to my experience, they are the most critical, the most suspicious and the least grateful of patients.

I venture here to relate a case that occurred with my father:

During his sojourn in Augusta, Ga., he had an infirmary for the treatment of slaves, when a wealthy planter sent to his institution a negro upon whom it became necessary to amputate the thigh. Sometime afterward the slave died, and the owner brought suit against my father, for his worth as a slave. This suit was brought by the Hon. Alexander H. Stephens. My father employed the Hon. Eli Cummings, ex-Governor of Georgia, and obtained the depositions of the noted surgeons Valentine Mott, Samuel D. Gross and Eli Geddings. After the reading of these depositions, the testimony was so overwhelmingly in favor of the defendant that the Hon. Alexander H. Stephens got up in court and dismissed the case at the plaintiff's cost.

The interesting features in this suit are: First, my father claimed to have made more reputation in the case than any other thing which up to that time had happened him; and, secondly, the strange occurrence of the gentlemen connected with the case, viz., that the Hon. Alexander H. Stephens, my father, and ex-Governor Cummings—all graduated in the same class from the University of Georgia, taking the first, second and third honors.

Let the medical profession act in harmony, let jealousies and rivalries be repressed, let them stand shoulder to shoulder in supporting and maintaining honorable medicine.

Let them down quackery and empiricism, let them rebuke the ignorant pretender and bring to justice the presumptuous charlatan, at the same time that they resist the unjust attacks that are so often made upon the meritorious members of the profession. Whenever one of these suffers wrong the reflex action is injustice to all.

Let us all remember that "united we stand, divided we fall." In union there is strength, and if the profession as one body were to unite for the purpose of preventing injustice being done its members by vexatious and oppressive damage suits, brought for the purpose of speculation by worthless and unscrupulous parties, the beneficial effect of such action would not only be immediate but permanent.

I, therefore, urge every physician and surgeon to make active and cordial exertions in this behalf, not only for his own security, but also for the safety of his brethren and for the welfare of the entire profession.

How to Abort Syphilis.

Feremal (*Annal de Lyon*) claims that Bichloride of Mercury (grs. xii to ℥i —) painted on a chancre as soon as it appears, kills all specific germs, and there will be no systemic manifestations. The local sore then to be treated on general principles.

CHLOROFORM ANESTHESIA.*

C. HOLTZCLAW, M.D., CHATTANOOGA, TENN.

When in the history of civilization, mankind had become physically degenerated; when the nervous organization increased so that the sensitive nerves could no longer endure pain, there came a universal urgent demand for something that would produce insensibility without destroying life. It was left to America to discover and grant this grand boon to suffering humanity.

It is unpleasant to know that there were three men who claimed this discovery and entered into a disagreeable and unfortunate controversy concerning it.

Without entering into the merits of the case, I take pleasure in saying that I have had the honor to see two of the greatest men in the medical world; whose names will be handed down to posterity; two of America's sons; Marion Sims, who revolutionized the treatment of diseases of women, and Crawford Long, who discovered anesthesia. Pardon these preliminary remarks, as they are only intended to excite your attention to some practical points on the subject of anesthesia by chloroform.

This agent was introduced about a year after ether, by J. Y. Simpson of Edinburg. It is needless to state that statistics show that chloroform is more dangerous than ether. The figures for the last four years, from carefully collected reports, show the alarming result that of 166,812 chloroform cases there were 63 deaths; a ratio of 1 to 2,647. Of 26,320 ether cases there were only two deaths; a ratio of 1 to 13,160. It has also been shown that about the same results have obtained for the last forty years.

Still in spite of the published results; in spite of the trade made by the writers; physicians continue to administer and patients to demand the administration of chloroform rather than ether. Why is this? Why the persistence in the use of this dangerous and baneful drug? The reasons are several. It is more pleasant to the patient; it is more easily administered; a less quantity is necessary; it is cheaper; less time is consumed; and there are left no bad after-effects, such as nausea, vomiting, bronchitis or nephritis. In the statistics to which reference has been made, the deaths that occurred were sudden and immediate. These were reported and registered. Deaths, from the subsequent effects of ether, such as nephritis, peumonitis and bronchitis are not reported.

It is my honest belief that as many or more deaths occur from these causes than from the immediate effect of chloroform. In 14 years experience, I have anesthetized, or had it done under my supervision, nearly 3,000 cases by chloroform, and without a death. During the same time I had 150 or 200 cases of ether narcosis followed by three deaths in from 1 to 3 weeks; one of which was from nephritic, and two from pulmonary complications induced by the ether.

I am satisfied that if the statistics would be carefuly collected of deaths occurring from subsequent effects of ether, there would be found more than from chloroform.

It is to the prevention of these sudden deaths that I desire to call your attention. They can be prevented to a very great extent, for they are almost invariably caused by ignorance or carelessness.

What is the cause of this sudden death? Investigators have shown that the prime cause is anemia of the brain affecting throat or lungs.

The results of the Hyderabad Commission show that it is from effect on the respiratory function and not on the heart action; that it is only necessary to watch the respiration and not keep the finger on the "deadly pulse;" and that so long as the breathing is normal there is nothing to fear from heart failure. In eight cases out of ten I think this idea is correct. But I think it well enough to watch both carefully and stimulate the one which should flag.

It has been my observation that chloroform is much better borne in warm cli-

*Read before the Tennessee State Medical Society, April, 1895.

mates than in cold. Why this is true I am unable to state. Excessive meat diet is claimed by some observers to render chloroform more dangerous. These are, however, only general considerations.

In the preliminary preparations to be observed where possible, always direct that the bowel be moved freely during the twenty-four hours before the contemplated operation, and that a light diet of soup or milk be allowed. No food should be taken for six hours immediately previous. There is a prevailing opinion that heart disease, or supposed heart-disease is a contraindiction to chloroform. This has been ably refuted by Dr. Fisher Clarke of Stockton, Cal., in an article in the *Medical Record*, April '94.

The administrator should endeavor to allay any nervous fears by examination of the heart for the moral effect if nothing more, and to quiet the mind of the patient by assurance, in a gentle voice and kind words, that there is no danger.

Fright has undoubtedly a weakening effect on the heart. Always give strychnia, sparteine or morphia with atropia, hypodermically, fifteen minutes before the operation.

See that the clothing is loose and open so that the respiratory movements of the chest and abdomen can be observed.

A perfectly prone decubitus is necessary. Never administer chloroform unless this can be obtained.

Death sometimes occurs with the first few inhalations, before any general anesthesia has commenced. Rosenberg, in an address to the Medical Society of Berlin, November 28, '94, showed that he had demonstrated that such death occurred, "through the effect on heart or lungs, due to reflex irritation originating in the nasal mucous membrane and transmitted to the nerves having a paralyzant action on heart and respiration." He also claimed that by "anesthethizing the mucous membrane of the nose with a four per cent. solution of cocaine, these reflex disturbances are prevented, and in view of the fact that cocaine is an antidote to chloroform, it absorption will in another way obviate its injurious effect."

This is certainly a very plausible idea. But in view of the fact that sudden death has been caused by spraying cocaine in the nasal mucous membrane, I have used and suggest the practice, in order to obviate both these dangers, of instructing the patient to breathe through the mouth instead to through the nose. With this method there is less coughing, strangling, and resistance, and less danger of syncope on the part of the patient.

The method of administration is a very important consideration. The paper cone stuffed with cotton or cloth is to be positively interdicted as being exceedingly dangerous. The ordinary towel, handkerchief or napkin is better, but presents a too concentrated vapor and is liable to excoriate whatever skin it touches. The various new inhalers are cumbersome, expensive and impracticable. The best inhaler is that introduced by Esmarch. Several varieties are sold by the instrument dealers, one of which I present to your notice. Another involving this principle, which I also show, can be bought at any general store for a dime. It is, as you see, an ordinary concavo-convex or hemispherical fruit-strainer or seive, made of woven wire and covered with yarn stocking cloth, and is attached to a handle. By this method it has been shown that, even with complete saturation of the cloth, the patient inhales only a twenty to forty per cent. dilution of the vapor, which is much less dangerous than one more concentrated. The face is to be covered by the inhaler, on which, in the beginning, only a few drops must be poured. Any coughing, any indication of spasm of the glottis, or any undue resistance on the part of the patient, necessitates the temporary removal of the inhaler. When this shall have ceased, commence again slowly, gradually increasing the supply, but with as much uniformity as possible by what is known as the "drop method." This method is best obtained by a drop-bottle suggested by myself, a specimen of which I take pleasure in presenting.

It consists practically of a ground-glass-stoppered bottle on the rim of which a small lip is blown. From this lip there extends a small groove downward about one-half the length of the neck. On the opposite side, about the middle of the neck, there is a small hole for the admission of air. In the ground-glass stopper, there are two grooves on opposite sides, extending one-half the length of the stopper. When in use the stopper is turned so that the grooves come in apposition with the air hole on one side and the groove in the

neck on the other. This adjustment can be so regulated as to permit a stream or only a drop to flow. When not in use, the stopper can be turned one-half way round, removing the grooves from the air hole on one side and the groove in the neck on the other, thus effectually closing the apertures so that the bottle can be carried in the satchel or pocket, and used as a supply bottle without chances of evaporation or leakage. I must insist upon the drop method with Esmarch's inhaler as being the most convenient, agreeable and safest method that can be used.

The existence of complete anesthesia can be demonstrated by the complete relaxation of muscles, or the absence of the reflexes.

Any indication of cardiac depression must be promptly overcome by the hypodermic injection of ammonia, alcohol, digitalis or nitro-glycerine, which must be kept ready for use.

The respiratory function demands the most careful attention; the cessation of which may be caused by the mechanical obstruction to entrance of air into the lungs by the falling back of the tongue into the throat, or by the closure of the epiglottis upon the glottis, or by paralysis of the nerves presiding over the function.

The alleviation of the first two is usually attempted by drawing the tongue forward with a pair of forceps or a suture. This procedure is unnecessary, unsurgical and brutal, as it has been anatomically demonstrated that it does not accomplish the desired results. All that is necessary to relieve this mechanical obstruction is to place the hand under the neck and elevate it, thus throwing the occiput backward and the chin upward. Then place the fingers under the rami of the lower jaw and press forcibly inward and upward. Immediate relief will invariably follow.

The differentiation between mechanical obstruction and paralysis of respiration is, that in the former there is an ineffectual attempt to breathe indicated by violent efforts of the intercostal muscles and diaphragm. With paralysis, this does not occur, and this condition should be regarded as serious and the attention directed to overcoming it.

Paralysis of respiration is far more common than cardiac syncope, but is more easily remedied. This can be accomplished by one of four methods. Remembering the fact that in chloroform narcosis the condition of the brain is that of anemia, the head should be promptly placed lower than the body, thus inviting the flow of blood to the brain. If necessary, grasp the patient's ankles and standing on a chair let his head hang down to the floor. Direct an assistant in the meanwhile to administer hypodermically a stimulant such as strychnia, nitro-glycerine, caffeine or alcohol. If neither of them are efficacious, perform Sylvester's method of artificial respiration. The fourth method is one which I now always use first, and since I discovered it three years ago, have never found it necessary to resort to the others. The method is simple, prompt in action and effectual. It consists simply in dilating the sphincter ani. I had noticed for several years that dilation of the sphincter ani, under anesthesia, would cause deep and rapid respiration with a peculiar snoring sound on inspiration. This, I supposed to be a reflex irritation of the respiratory centre through the sympathetic system. Operating before the class of the Chattanooga Medical College upon a case of fissure-in-ano under chloroform anesthesia, my chloroformist suddenly and frantically announced that the patient had stopped breathing. Suddenly it occurred to me to test the theoretical idea of reflex irritation. Immediately I rapidly dilated the sphincter ani and was promptly rewarded by commencement of respiration. Since then I have had occasion to use the method six or seven times, and have invariably found it to be successful.

Above all things, in chloroform accidents retain your presence of mind and do not allow yourself to become excited. The patient needs the active, prompt and intelligent attention which can not be given in a flustrated state.

There is another important point to which I desire to call attention, and that is the employment of incompetent persons to administer chloroform. The task is usually relegated to some inexperienced medical student, or to some careless or incompetent doctor, who, either from curiosity in watching the operation, from characteristic inattention or from absolute ignorance does not observe or appreciate the signs of approaching danger, or know how to treat the condition when it occurs. Always obtain the most careful,

competent and painstaking physician possible, to administer chloroform; one who will give his undivided attention to the performance; who understands and appreciates the danger signals and can promptly meet them with the proper remedy.

The employment of incompetents for the administration of chloroform has produced many deaths and will continue to cause many more if persisted in.

It is no professional derogation or disgrace to administer anesthetics, for to do it well requires just as much scientific knowledge, just as much practical art as to perform a laparotomy or to amputate a leg.

A celebrated German surgeon was once performing an operation, when the chloroformist, a medical student, became so engaged in the operation that he neglected the patient, who coming out from the influence of the anesthetic rose to an upright position and began to look wildly around. The professor administered a scathing rebuke to his assistant by yelling to the patient, "Lie down there; you have got nearly as much curiosity as that medical student."

In conclusion, the deductions which I wish to draw for the safe administration of chloroform are:

1. The employment of a competent physician to give it.
2. No food should be allowed for six hours previous.
3. Quiet the mind of the patient by examination of the heart and the assurance of no danger.
4. Obtain a prone position and loose clothing.
5. The hypodermic injection of morphia with atropia, or strychnia.
6. Esmarch's inhaler, with my dropper.
7. Begin with very small quantity and remove inhaler when there is coughing or undue resistance.
8. Insist with mouth breathing so long as consciousness lasts.
9. In accidents, lower head, dilate sphincter ani, and use artificial respiration.

The strict observance of these rules positively insures the administration of chloroform to be as safe as that of ether; and leads me to declare that as I have never had a death from chloroform, I intend to use it until I do have one.

TRANSLATIONS.

DEATH FROM HANGING AFTER TRACHEOTOMY.*

DR REINEBOTH, HALLE.

On April 17, tracheotomy was performed on a patient on account of cancerous tumors of the neck which interfered with deglutition and respiration. Nutrition was carried on by means of an œsophageal tube until June 27, when the obstruction became insuperable. At 10.30 P. M. of June 30, the patient left his bed to go to a closet, and was not again seen until a search was instituted, which resulted in the discovery of his body at 1.30 A.. M. The body was clothed in a shirt, drawers and stockings, and was suspended from the lowest crotch of an acacia tree on a hillside. The knees were bent, and the dorsal surface of the feet and the toes touched the sloping ground. The noose was above the canula. From pieces of rope, a handkerchief found in the crotch of a taller tree, and other evidences, it appeared that some time had been spent in selecting a place for suicide, while one of the watchmen had heard a rustling in the bushes in the neighborhood of the acacia at about midnight. The body, however, at half past one, was quite cold and stiff, indicating that death must have occurred quite soon after hanging, The position of the body was such that if the patient had retained consciousness even long enough to notice that he could still breathe, he would probably have risen to his feet. A layman would certainly have

*Condensed translation from the Quarterly of Forensic Medicine and Public Sanitation, 2d vol., 1895, by A. L Benedict, A. M., M, D., of Buffalo.

considered that stoppage of respiration would be inseparable from suicide by hanging. It is probable, therefore, that consciousness was immediately lost, just as in death by hanging under ordinary circumstances, and from the same cause, compression of the great cervical vessels. In spite of the seriousness of his disease, the patient's strength was normal, as, indeed, is shown by the preparations made for suicide.

At the post-mortem examination there was found anæmia of the cerebrum, slight distension of the vessels of the pia, engorgement of the pons and medulla, and marked distension of the arteries of the base. The mechanical relations of the circulation for the head, and especially for the brain, are the same for hanging with and without access of air to the lungs. Evidently the tumors of the neck had not prevented compression of the vessels. The lack of ecchymoses on the serous membranes of the thorax deserves mention; otherwise, the presence of pulmonary gangrene, pneumonia and pleurisy, which had been diagnosed during life, obscured the condition of the thoracic viscera so that it was not significant in the present connection. There was no special hyperæmia of the abdominal organs.

Mahon has reported the case of a highwayman condemned to death in London in 1801. A young surgeon was persuaded to open the trachea and introduce a small canula before the hanging. After execution the body was delivered to the relatives, who took it without delay to the surgeon. He opened the jugular vein, and attempted in other ways to resuscitate the man. The latter opened his eyes, gave a deep sigh, again fell into a swoon and died. The details of this case are not considered altogether reliable. A case is also referred to, contributed by Taylor to Smith's "Legal Medicine," in which the mere mention is made that opening the trachea prolonged life during hanging to three-quarters of an hour. Deininger, in 1884, reported a case of death from hanging in which compression of the air passages was prevented by the lodgment of a fixed knot under the chin. The body was found half sitting, with the buttocks only a hand's breadth from the ground and the heels resting on the ground. Erik Holst has also published a similar case of suicide. From lack of imprint of the noose on the neck from the thyroid to the right ear, it seemed probable that the passage of air was not hindered. A similar case of suicide is mentioned in Schmidt's *Annual*, vol. 85, in which, however, the base of the tongue closed the pharynx and larynx.

[The translator would suggest that some of these cases might have been murder with subsequent suspension to simulate suicide.]

Schwenninger, experimenting with rabbits and cats, Paul Baron with dogs (the latter quotes, also, von Mahon and von Redrig), found that death did not occur from hanging after tracheotomy. Tammasia has made a long series of experiments in order to determine the relative importance of compression of the vessels, the vagi and the trachea in the production of death. The details not being given, only the general conclusion can be stated that, after compression of the vessels of the neck and the vagi, no sudden death occurred. Misuraca also experimented on the same lines, using dogs. The details of his experiments also are unknown to the writer, but he came to the conclusion that, though previous tracheotomy did not prevent death from hanging, the appearances both before and after death were different from those of ordinary hanging.

The writer experimented with two series of five rabbits each, the former being simply hanged, the latter hanged after tracheotomy. Immediately after simple hanging there was a stoppage of respiration and the pupils became somewhat contracted. Then followed regular, violent, inspiratory movements. A corresponding expiratory movement could not be detected. After a variable duration of these respiratory movements, there were violent extensor spasms separated by long pauses. A pretty sudden maximum dilatation of the pupil coincided with the cessation of the spasms; the corneal reflex was lost and respiratory movements ceased. In two cases, the so-called terminal respiratory movements were noticed immediately before death. The heart continued to beat up to about a minute and a-half after the cessation of respiratory movements. Death resulted in all these cases in from three to three and a-half minutes. With strangulation is connected a marked rise of temperature, amounting to about 40°C., at the moment of death.

The symptomatology of death in the second series of animals, hanged after tracheotomy, differs most conspicuously in the delay of death. There intervened from 10¼ to 19¼ minutes between suspension and death in the second series. Even in this series, the heart beat persisted only about a minute and a-half after the cessation of respiratory movements. Terminal respiratory movements were noted in three animals on whom tracheotomy had been performed, in the other two the suspension was discontinued before this stage was reached. In one of these two, the thickness of the cord prevented compression, and the rabbit was cut down at the end of thirty minutes and dispatched with a blow of the hand.

Appearances indicated that the rabbits hanged without tracheotomy, were unconscious. It was difficult to decide this question in the case of the second series. One rabbit pricked up its ears at a shrill whistle after two and three-quarters minutes suspension. Another moved its eyes after seven and a-half minutes. Baron's dogs were conscious and wagged their tails. The absence of corneal reflex, however, showed that they must have been unconscious part of the time.

In order to learn if the stretching movements were really convulsions, the last animal was cut down and freed from the noose six and a-half minutes after the beginning of the experiment. It turned wildly about its long axis, six or seven times, with its head and legs stretched backward and then remained a short time lying on its side with the head raised; then it sat up. It seems improbable to the writer and to Baron that the movements were anything else than genuine convulsions.

The marked rise of temperature noted in the first series was not observed in the second. In one of the latter animals, the rise was only from 38.3° to 39.3° C., the latter temperature being taken immediately after death, in the abdominal cavity. In the experiment in which death occurred nineteen minutes after suspension, the rise was only .1° C., before death and .3° after death.

The brains of the animals of the first series all showed the same changes. Very delicate and slightly branched vessels were visible in the pia along the greater fissures. The large vessels of the base were slightly distended and the brain substance was pale. In the second series, the whole pia was marked with numerous branching vessels filled to the smallest twigs. The arteries of the base were likewise distended to the finest branches. The pleuræ of the first series showed numerous ecchymoses; those of the second series only a few. Since, in the latter series, the aspiratory force of the thorax cannot be considered, the few ecchymoses must be ascribed to vaso-motor spasm. There was just as little indication of pulmonary hyperæmia in the one series as in the other. The animals which were simply strangled showed a more marked fullness of either the right auricle, right ventricle, or both, as compared with the left side of the heart. In both series, the fluid contents of the heart surpassed the volume of the clots. The liver was congested in all cases. The condition of the spleen and of the intestine varied. The kidneys uniformly showed a purple border at the boundary of the medulla.

Regarding the acidity (?) of the blood, the same result was obtained in all nine instances in which it was examined—including the rabbit killed by a blow. By spectroscopic examination the blood from the left ventricle showed only one absorption band, that of reduced hæmoglobin. Kotelewski's investigations agree that the blood of a corpse contains only reduced hæmoglobin. This substance is found as early as fifteen minutes after death.

N.B.—The translator takes occasion to protest against experiments on animals such as are detailed by Dr. Reineboth. These experiments have simply confirmed theoretical speculations. Their practical bearing is, at most, a medico-legal one. It must be very evident that the mere difference in weight prevents the exact application of these experiments to the case of human beings. We might argue that because a cat can jump thirty times her height without injury, a man can do the same; on the contrary, at the same distance, the lighter animal would sustain less injury than the heavier and larger one. It does not seem possible that a rabbit's weight can put any such tension on a cord as to cause compression of the cervical vessels or the vagi comparable to that effected by a weight of 150 pounds,

more or less, as in the case of human suicide. This is one of the instances in which a difference in degree amounts practically to a difference in kind. Experiments of this nature tend to bring into disrepute vivisections performed with an entire absence of pain on the part of the animal and destined to fulfil some useful purpose.

CORRESPONDENCE.

Editor of the Medical and Surgical Reporter.

SIR:—In Dr. Keiser's admirable article in your issue of May 11, 1895, he makes reference to the "King's Evil" in such a way as to apparently imply that the English people were alone in their belief in the efficacy of the "Royal touch." The practice was not peculiar to England. The French kings laid claim to the power of healing by "touch," even from the time of Anne of Clovis. And on Easter Sunday, 1686, Louis XIV "touched" 1,600 persons. But even that proudest of French kings did not ascribe the cure to the *royal* touch, for he used the following words: "*Le roy te touche, Dieu te guerisse.*"

The belief was in the descendent of a Saint, not in the King. When Charles Edward Stuart, the Young Pretender, would convince his followers of his legitamacy in 1745, he "touched" a scrofulous girl.

The office for the ceremony of "touching," which remain in the book of Common Prayer to 1719, goes to show that the power of healing was not due to the kingly office but inherited from the Saintly Confessor. Happily the whole superstition is removed fromamongst us: but it is well to clearly keep in view the actual belief of the time and not be misled by the very misleading title the "royal touch."

The second matter I would draw attention to is the "Sympathetic Ointment" of Kenelme Digby. No greater evidence of a false theory producing good results ever happened in medicine than the use of Digby's powder. In his pamphlet "*Of the cure of Wounds by the Powder of Sympathy,*" published in London A.D., 1650, Digby tells an absurd story of a Persian who traveled across Asia and Europe to confide to him the secret of the "Powder of Sympathy." It is difficult to say what Digby's object was in the story or in the introduction of the powder.

Except Defoe, no Englishman was in so many scrapes and strange scenes. He had belonged to all the political parties of his time and had fought duels with every class of politicians. Amongst his other studies, medicine came in for some attention and it is just possible that from observation he found the frequent dressing of wounds injurious, and that he invented the fable to correct the faulty practice of the surgeons of his day. Digby was quite capable of inventing the story to gain general acceptance for his powder, and we cannot think that the theory of "sympathy" put forward was seriously believed in by the friend of Decartes.

GEORGE FOY.

DUBLIN, June 2, 1895.

Tearing Out of Nerves as a Cure of Neuralgia.

Adenot, of the French Congress of Surgery (*Revue de Chirurgie*), advocated, in neuralgias, section of the nerve as high up as possible, then seizing the peripheral end with a pair of forceps it is to be wound around it until as much is removed as possible. Eight or ten centimetres can thus be taken away. Good results have been obtanied by this method of treatment by Mollière, Tripier, and Gangolphe. Chipault also spoke favorably of the method, having had a complete success with it in a case of neuralgia of the forearm which had previously resisted section of the ulnar nerve.

Menorrhagic Chlorosis.

Dr. Ch. Ligeois prescribes:

Sulphate of iron.....	gr. xxxviii.
Ex. of hyoscyamus.....	gr. xv.
Alcoholic extract of hydras. canadensis.....	gr. lxxviii.
Powdered licorice root.....	gr. lxxviii.

Make 100 pills Sig: Two at each meal, both during and between the menstrual periods.

THE MEDICAL AND SURGICAL REPORTER

ISSUED EVERY SATURDAY

Address all communications to P. O. Box 843, Philadelphia, Pa.

HAROLD H. KYNETT, A.M., M.D.
Editor.

RODERIC C. PENFIELD
Publisher.

Editorial Offices, 1026 Arch Street, Philadelphia, Pa.

Entered as second-class matter at Asbury Park, N. J.

TERMS:—Three Dollars a year in advance. Sent four months on trial for $1.00.

REMITTANCES should be made payable to the Publisher only, and should be made by Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We invite contributions of value to the profession, and if published originally in THE REPORTER such will be paid for at liberal rates, or a limited number of copies of THE REPORTER will be supplied, as the author may elect. Hereafter where reprints are desired writers are requested to make a note of that fact on the first page of the MS., but must order reprints directly from the publisher, who will supply the same at cost rates. Contributors should inclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, JUNE 15, 1895.

EDITORIAL.

"IN THE BENEVOLENCE BUSINESS."

At a recent anniversary of one of the large and needy hospitals in the millionaire district of this city, says the *Medical Record,* a speaker filled with enthusiasm for the benefits of the present hospital system is reported to have said that one of its greatest boons was the saving of expense to the rich man. In proof of such an unjust and outrageous claim he bolstered his statement by comparing the items of expense when a patient was treated at an ordinary hotel by his regular medical attendant with those in a well-equipped charity institution supported by the liberal contributions of a Christian organization. Instead of a daily expenditure of $5 for hotel accommodations, $5 for a trained nurse, $5 per visit for the physician, and $5 more for the board of the nurse, not to speak of the cost of the medicines from an expensive pharmacy, the patient who entered the hospital in question needed only to pay for his board and a private room. All other outlays were unnecessary and were included in the one item named.

"Naturally in this connection we think of the physician, who is the only one whose services are virtually considered of no account. The high price of the room added to the donations of the charitable enable the hospital to make a handsome profit, even including the general expenses for nurses, medicines, instruments and dressings. The attending physician or surgeon, who might be looked upon as the real personage who makes any hospital what it is, is not only entirely ignored, but a deliberate attempt is made to swindle him and his outside associates in attempts at gaining a legitimate livelihood. It would appear from all this that the evolution of medical charity is distinctly in the direction of eliminating the doctor. Another step in this direction would be for hospital managers to go into the wholesale proprietary medicine business and prescribe remedies on their own ac-

count free of cost to the patients. Why should not money be invested as well and as profitably in medical charities and millionaire clinics as in railroads, wheat and mining stock? The men who run the hospitals can command all the needful capital on the hypocritical plea of charity to the poor, can obtain medical services free, can build magnificent edifices, endow beds for cast-off servants, beg for church subscriptions, and what is to hinder them from running the medical charity business entirely in their own interests? They are doing it all the time, though less openly than the distinguished speaker in question has so frankly admitted."

Just so! "What are you going to do about it?"

A "well-equipped charity institution supported by the liberal contributions of a *Christian* organization" is good, but a well-equipped charity institution supported by the liberal contributions of an organization, to which, in the popular estimation, the term Christian would be utterly irrelevant and misapplied—for instance the ordinary State legislature—is much better in that it is a cheaper method of securing the capital necessary to enable professional philanthropists to carry on the business of benevolence and compete with the untaxed foreign production of medical paupers.

That this liberality obtains in the Commonwealth of Pennsylvania (in the case of this legislative body whose proclivities may be presumed on the theory that actions speak louder than words, no attempt has ever been made to misapply the term *Christian*), will appear from the appended incomplete list of appropriations to medical pauper-factories as reported by the Appropriation Committee at the present session. The first column of figures represents the modest amounts asked for and the second column the parsimonious alms to the needy medicants as pared down by a miserly committee.

Medico-Chirurgical Hospital	170,000	150,000
University of Pennsylvania	500,000	200,000

Conoquennessing Valley Hospital	12,500	12,500
Gynecean Hospital, Philadelphia	35,000	25,000

Many ideas of interest to medical men may be inferred from a thoughtful consideration of these figures in connection with the remarks above quoted. It must be admitted that the position of a legislature in philanthropizing with the funds of its constituents is not an easy though, perhaps, an enviable one. For, on the one hand, public opinion, although it favors a liberal support of all charities for the genuinely helpless and needy, and especially for such charities as are "entirely dependent upon voluntary contributions' —from private individuals, will not at least theoretically, tolerate the reckless or injudicious expenditure of the State's treasure, nor the subversion of public money to the service of ends confessedly personal. On general principles, the money of the people must be applied only to genuine needs. Too much must not disappear in transit on its way to do its designated service. It must not be loosely thrown into the hands of irresponsible parties who will fail to ensure its certain and conscientious application to the pur-

poses for which it was granted. Practice has demonstrated that reckless, indiscriminate, injudicious, and needless handling of the public funds is something more than tempting to petty larceny from the tax-payer; it is liable to breed the gentleman-pauper (thief), and curiously enough, seems to have a tendency to impair confidence in law-makers and in public officials generally.

On the other hand, failure to furnish sufficient protection to the industry will drive professional philanthropists out of the benevolence business as soon as the outlay becomes equal to or exceeds the income.

Furthermore, too niggardly contributions to worthy objects would be liable to produce in the popular mind a confusion of the State with the Church, and religion is never improved by an alloy of politics.

The entire withdrawal of "State support" will go a long way towards solving the "hospital question."

ABSTRACTS.

THE THERAPEUTIC USES OF GUAIACOL.

Although the therapeutic history of guaiacol has been known for the past few years, the only clinical observations on which any reliance can be placed with regard to its rational employment are of quite recent date. Formerly, guaiacol was extracted from various kinds of creosote, impure products which were more or less charged with phenol and, consequently, likely to give rise to accidents. Since 1893, a pure product, perfectly definite, has been obtained by synthesis, by M. Béhal and M. Choay. Synthetic crystallized guaiacol should replace the liquid guaiacols in materia medica. It is the same which was used during the present year by M. Linossier, M. Lannois, M. Guinard and others, in experiments, the results of which illustrate the therapeutic value of guaiacol for external and internal use.

Internally, guaiacol is generally well borne by the stomach owing to its local anæsthetic action. It may be given by the mouth or hypodermically. When given by the mouth, the dose is from 1.6 grain to 8 grains during the twenty-four hours; in pills containing from 10.8 to 11.6 grain in capsules containing the same quantity of guaiacol in an oily solution; or in alcoholic solutions, as, for example: 1. Guaiacol, 150 grs.; rum, 450 grs.; distilled water, 6½ ounces.—From eight to ten teaspoonfuls may be taken every day, in milk or water. 2. Guaiacol, 150 grs.; vin de Bagnols, 33 ounces.—From one to three dessertspoonfuls may be taken during the day.

When hypodermically administered, smaller doses are used; from 1.6 to 4 grains of guaiacol dissolved in perfectly sterilized and neutral olive oil. A one-to-five solution is generally used, but equal parts may be employed.

Guaiacol may be used in:—

Pulmonary phthisis. It seems to be especially indicated in cases where the progress of the phthisis is sluggish, succeeding the period of softening with abundant expectoration. It should be handed prudently in erethetic phthisis with a tendency to congestion and hæmoptysis, and in tuberculosis in the beginning. The drug should be given, according to the condition of the digestive canal, by the mouth or hypodermically. The hypodermic injections of Weill and of Diamantberger are preferred in the beginning by certain clinicians. Weill employed the following formula: Crystallized guaiacol, 75 grains; sterillized oil, 3-25 ounces. From two to three syringefuls of this solution injected every day.

2. Chronic bronchitis, dilatation of the bronchi, fœtid bronchitis, and pulmonary gangrene. In three cases of pulmonary gangrene, Weill obtained very good results with hypodermic injections of guaiacol.

The solution should be more concentrated than that used in phthisis; for instance, 15 grains of guaiacol and 150 grains of sterilized oil. In pulmonary gangrene, according to M. Lop, from one to four syringefuls may be injected every day. The same procedure and the same doses have been successfully tried in fœtid bronchitis, and in dilatation of the bronchi with sphacelus of the mucous membrane. In chronic bronchitis and in dilatation of the bronchi, Grainger Stewart recommends guaiacol not only in hypodermic injections but in intralaryngeal injections. He employed the following solution: Crystallized guaiacol, two parts; menthol, ten parts; sterilized olive oil, eighty-eight parts.—Sixty grains of this were injected into the larynx twice a day. M. Naught also employed this method in fœtid bronchitis, with good results, All laryngologists, at present, use guaiacol for direct injections into the larynx and the trachea.

3. Purulent pleurisy. In this affection Robertson employed injections of guaiacol with very good results. He found that they were efficacious in diminishing the purulent secretion after empyema.

In the external use of guaiacol painting has become a common practice, and it is as important as the hypodermic injections, or its administration by the mouth. It has been used pure, or with equal parts of sterilized olive oil or glycerin. For the first painting, thirty grains of oil solution should not be exceeded, as stronger doses have provoked symptoms of collapse. The solution should be applied over a large surface. The preferred regions may be the forearm or the calf of the leg. Guaiacol has also been employed in combination with tincture of iodide and vaseline.

Painting with this drug has been used.

1. Tuberculosis. In this disease the paintings seem to have a powerful antipyretic action. In miliary tuberculosis and in the acute attacks that occur during the course of chronic tuberculosis, according to Bard, Courmont and Boix guaiacol, gives the most remarkable results. Boix reported several cases where not only small doses resulted in rapid and intense effects on the fever and on the general condition, but the effects were apparently lasting and definitive. In several cases there were bacilli in the sputum. The drug should not be used in the treatment of very feeble persons in the last stage; moreover, it has no action on the hectic fever of this period.

2. Typhoid fever. Montagnon employed paintings with guaiacol over the inguinal region when the temperature was high, and he was able to combat hyperthermia in twenty patients, Eight grains were used at a time, and not more than thirty grains during the day. With repeated paintings Moisy was able to maintain an almost normal temperature, and he noticed that the antithermic action of the drug seemed to increase. Cheron, however, pointed out the dangers that might follow a too prolonged use of the drug, owing to the insufficient renal elimination of guaiacol. Montagnon recommends the use of guaiacol especially in cases where the cold bath is contraindicated. Desplats also obtained very good results in typhoid fever with guaiacol.

3. Pleurisy. Miron Sigalea painted the entire affected side twice a day with the the following mixture: Guaiacol, 45 grains; glycerin and tincture of iodine, each, 300 grains. He has also seen this treatment succeed in recurring effusions after a first thoracentesis. In these cases the guaiacol appeared to have a diuretic effect, which was also observed in a case of scarlatinous nephritis with anasarca and anuria. Desplats also found this diuretic action in typhoid fever and in typhus.

4. Infectious pyæmia. In influenza, pneumonia, rheumatism, etc., painting with guaiacol has an ordinary antipyretic action. In intermittent fever Kohos moderated the attacks in the beginning by injecting a mixture of guaiacol and lanolin over the spleen. In erysipelas of the face the paintings, according to Bard, may diminish the intensity and gravity of the affection. In all affections where the renal elimination may be insufficient, the administration of guaiacol should be cautiously made and its action carefully watched.

5. Pultaceous angina and amygdalitis. According to Darboue, Raymond, Rhodes and others, pharyngeal paintings give very good results in combating not only the fever, but the pain. The glycerin solution is preferable to the oily solution, and, for an adult, the two ingredients are prescribed in equal parts. For children, however, the dose should be weaker, one part of guaiacol and three of glycerin,

and its action closely watched. The first burning is sharp and the taste rather disagreeable, but the relief is rapid. The difficulties of delugtition are very much diminished.

6. Neuralgia. Painting with guaiacol seemed to give good good results in sciatica, in intercostal neuralgia, and in coxalgia. Balzer employed the following ointment in blennorrhagic orchitis: Guaiacol, 75 grs.; vaseline, 450 grs. In the very painful forms he applied the first painting over the abdomino-inguinal region with from thirty to forty-five grains of pure guaiacol, and after the first sharp burning relief generally occurred at the end of about half an hour.

The dominating action of the drug is antithermic. This has been observed especially in cases of tuberculosis, although this action of the drug is successful in other pyrexiæ. The analgetic action of guaiacol must not be overlooked, for it has rendered great service in certain painful affections in the treatment of which we have often been powerless to combat the element of pain with other drugs.—*Presse Medicale.*

THE USE OF ALCOHOL IN SICK CHILDREN.

Dr. Seibert, in a paper read before the Section on Pediatrics, New York Academy of Medicine, March 14, 1895, states:—(*Archives of Pediatrics*), while Demme in his classical study on "The Influence of Alcohol upon the Organism of the Child," published in 1891, has given a review of all the possibilities of chronic alcoholic poisoning in children, he only alludes to its use at the bedside, by expressing the wish that it may there, never be entirely suppressed. Strümpell's masterly paper, read in September of 1893 at the 65th annual meeting of German Physicians, "On the Alcohol Question from the Medical Point of View," points out the pathological changes caused by the habitual moderate use of alcohol in adults, but alludes to children in only a cursory manner; and though an excellent medical sermon preached to German physicans upon the evils of the beer-drinking habit of the Teutonic race, no precise statements as to when and where alcohol should be employed is found therein any more than in Demme's work.

If I attempt to describe some of the conditions in sick children where alcohol may, and may not be of use, I do so with the distinct understanding that in the future the number of these indications may be changed, and that the opinions expressed are strictly my own, and therefore open to criticism to all who may think otherwise.

1. Gastro-Enteritis. In an article on "Acute Gastritis in Infants," published in 1884 (*Yahrbuch für Kinderheil Kunde*); I pointed out the necessity of forbidding the drinking of beer to mothers nursing infants suffering from gastro-enteritis. In a paper published five years ago, I said: "We can exclude all forms of gastro intestinal disturbances in children from the list of diseases where alcohol is beneficial. In acute cases, even in cholera infantum, large quantities of water and smaller ones of black coffee or tea, will stimulate more than any quantity or quality of alcohol, besides, not irritating the mucous membrane, already in a diseased condition."

In an article on the "Mechanical Treatment of Gastro-Enteritis in Children" (*Medic. Monatsschrift*, 1889) I pointed out the fact that the only rational course for the therapeutist to pursue in these cases, was to rid the alimentary canal as soon as possible of its bacterial invasion, and to stimulate by supplying the blood and the tissues with large quantities of water. Epstein in 1891, (*Festschrift* to Prof. Henoch) arrived at the same conclusion, and to-day this indication is universally recognized. To attempt the stimulation of such patients with alcohol after cleansing the alimentary canal is superfluous, but to give alcohol to enteritic children while yet the decomposing milk remains in the intestine and the development of bacteria is perhaps supported by the constant supply of milk given to the child, is irrational and harmful.

2. Typhoid.—In connection with all the varieties of acute and chronic gastro-enteritis, from the most intense form of cholera infantum down to the mildest type of dyspepsia, we had better dispose of the

possible use of alcohol in the typhoid of children. Brown's theory of sthenia and asthenia, and Todd's teachings had spread the alcohol treatment of typhoid fever from England all over Christendom. Enormous quantities were given. Demme tells us, "that it was not unusual to give two to three bottles of strong red wine in addition to large quantities of champagne and cognac to an adult in the course of twenty-four hours; sometimes a quart of cognac was given daily."

I have used alcohol in typhoid patients children and adults, in private and in hospital practice during the last seven years only in emergencies. Ninety-five per cent. of my patients never taste it. Even during convalesence, alcohol can only retard and impair the digestive ability of the stomach by causing catarrh and decreasing its motion, thereby giving rise to abnormal bacterial activity in spite of hydrocloric acid, as Kaufmann, of New York, has recently shown (*Berl. Klin. Woch.*, Feb., 1895); and this at a time when this organ is expected to perform more work, just after having been weakened by the disease and possibly the medicines of the physician.

As typhoid usually runs a mild course in children and collapse will hardly ever be observed, if but the proper diet is adhered to, we may safely say that alcohol ought not to be given to typhoidal children, as it will increase gastric and intestinal fermentation and so the systemic infection. Alcohol does not disinfect the alimentary canal any more than the blood, as modern bacteriological research has demonstrated. As an antipyretic in typhoid, alcohol has at no time been taken seriously by any physicians of note since clinical thermometers are in use, and its sedative action can much better be brought about by safer remedies.

3. In fibrinous and broncho-pneumonia in children alcohol has been given in enormous quantities, and it has become a habit with some of us to occasionally point with pride "at the very large quantity of alcohol which young children tolerate during pneumonia." As to this "toleration" I will here ask, "what could these little sufferers do but to tolerate this abuse?" I am sure they would have protested if they had been older instead of "young" children. This idea to make up for the small size of the patient by the large size of the whiskey-bottle, was based upon our ignorance as to the true cause of heart weakness in catarrhal and croupous pneumonia. Klemperer and his brother and others have isolated the toxines of some varieties of pneumonia and have demonstrated their destructive action upon the nerve centres.

I do not use alcohol in pneumonic children at all, so long as they are willing to swallow cold water, tea, coffee and broths. In a collapse, threatening or present, I do use it, in good doses and in concentrated form, but I hold that we can not prevent heart failure not yet in evidence, by the regular administration of small or large quantities of alcohol. On the contrary, I am convinced that by regularly bringing this quick-acting poison in contact with the stomach and the nerve-centres, we cause pathological conditions well known to us in the healthy child after drinking liquor, but which we do not recognize in the patient, partly because the symptoms of the disease disguise them, and partly because we are blinded by our own success in increasing the volume of the pulse (due to vaso-motor paralysis), to see the harm we do.

An alcohol-fed child will digest still less during pneumonia than one who's stomach is not constantly insulted in this way. So it is in healthy children and so it is in sick children, but the damage done in the latter is by far the greater. The idea that the toxines of pneumonia counteract the alcohol so as to destroy its toxic effects and to leave only its benificent properities, is one of those many pious grey theories, ripe and ready to be thrown into the waste-paper basket of modern medical knowledge.

Alcohol-fed pneumonic children do not regain their appetite and digestive power after the attack is over as others treated without it, for the resulting gastritis will as surely then be in evidence as the one in the adult male who returns from a protracted spree. The anæmia and malnutrition must therefore be increased by the alcohol treatment, aside of the nervousness due to destroyed nerve-tissue, and the ultimate complete recovery to the normal state must be prolonged.

Insufficiency of the heart's action in pneumonia in children is due to the destructive action of the absorbed toxines upon the nerve tissue and to insufficient oxydation of the blood, *ergo* carbonic acid gas poisoning. Against the latter, a constant supply of fresh cool air (irrespective

of the time-honored 70° F. temperature of the sick room), will guard well in most cases; against the action of toxines we are practically powerless. Alcohol does not decrease the strength of the toxines in the blood any more than in a test-tube, and we have good cause to infer that the blood can come up to the emergency much better without its vitality and reactive power in producing anti-toxines being interfered with by balcohol.

The nerve tissues, peripheral and central, are *never* benefited by alcohol. Destruction of nerve tissue is the well-recognized mission of all alcohol brought into the system, even in repeated small doses, as Strümpell has shown. And what about the reaction following each exciting dose? Depression, in exact proportion to the amount of alcohol taken, follows in every instance in the healthy human body, and also dnring pneumonia, leaving the nerve-centres guarding the heart's action certainly not in an improved condition. Abundant clinical experience, added to known pathological facts, therefore, have induced me to use alcohol in pneumonic children only in occasional emergencies, where smaller doses will do more good and less harm.

4. In scarlatina alcohol is not tolerated by the stomach at all during the first few days, as nausea usually teaches us. In malignant cases, causing destruction of blood-cells and death in from six to forty-eight hours, I have never seen the slightest improvement, even hwen large doses of ether and alcohol were given hypodermically. In mild cases, without pharyngeal necrosis alcohol is entirely out of place, as well as in *measles*; as the hyperæmia of the cutaneous capillaries by partial paralysis of the vaso-motor nerves (from which cause we noticed the flushed face of the drinker) can only be increased, adding to the distress of the child and the better accommodation of the bacteria in the skin.

In septic conditions during scarlatina, induced by absorption from the pharyngeal necrotic tissue into the cervical lymph-nodes and the general circulation, now and then causing abscess, a judicious dose of light wine, or whiskey in water, appears to be of benefit, relieving pain and insomnia. It is my habit to give coffee, tea, cocoa and camphor during daytime, and a fair dose of alcohol at night, so as to somewhat subdue the excitement and restlessness caused by necessary irrigations of the upper air-passages. With such a night-cap, combined with a carefully selected dose of an antipyrine solution (this given per rectum), I have produced refreshing sleep, but often when gastro-intestinal disturbance caused me to abandon its use again, the children seemed not to be the worse for its want.

Some fourteen years, ago I treated a boy of six years, for two months, during a severe attack of septic scarlatina. His father kept a wine shop and alcohol was freely given. Four weeks after my last visit I found the little fellow suffering from a peculiar form of gastritis, allowing him to eat well, but also compelling him to leave the table and to vomit up all of the food taken. He confided to me the secret that he had formed the habit of not alone taking all the wine given to him, but also to help himself to extra drinks whenever no one was near. A speedy removal to a temperance boarding house in the Orange mountains promptly cured him of his alcoholic gastritis.

5. In dyphtheria the free use of alcohol has been universal. The enormous mortality of about 40 per cent., in places supplied with the best medical talent, like London, Paris, Berlin and New York, does not exactly speak for its value in this ailment. In mild cases I have not used it at all for years, and I doubt very much whether my patients suffering from severe attacks (showing general invasion of the naso-pharyngeal cavity from the start), derived any benefit from the large doses I gave them. The diphtheric paralysis caused by the toxin of the Loeffler bacilli can certainly not be prevented by alcohol, no matter how much is given, but that we may assist a myo-carditic heart-muscle to do its work, is piously believed by many. I doubt it and considering that Strümpell claims to have seen degeneration of the myocardium from habitual moderate doses of alcohol, we may ask if not possibly large doses at least aid the diphtheria virus in increasing degeneration here where we expected to help instead of to hinder? Certainly an open question, waiting for investigation.

So far I have given alcohol in diphtheria whenever the heart seemed to give out, but then in large doses and only for a day or two. Frequent small doses may pave the way for the toxines into nerve-tissue by

aiding in attacking their structure. I have given a strong man, on the third day of a virulent attack of gangrenous diphtheria, when his pulse was 140 and his rectal temperature 96° F., a full quart of French cognac in twenty-four hours, after which time his pulse fell to 120 and his temperature rose to 104.5° F., but no more after this; and a girl of six with a rectal temperature of 97° F. and a pulse of 138 on the fifth day of a severe attack of diphtheria, half a pint of rye whiskey in twelve hours, and they both recovered, and I fondly hope that this treatment saved their lives, but my scepticism does not permit me to assert this, because thorough local treatment (which had not been used till then), certainly stopped the further spreading of the local affection, and possibly the antitoxines developed in the blood in spite of the alcohol, did the rest. In twenty-seven cases of diphtheria seen by me since Dec. 1, 1894, and treated by Behring's serum, among which were five with laryngeal infection, alcohol was given to one child of eleven months, and this was the only one that died.

As most cases of diphtheria are mixed infections, caused by different varieties of bacteria associated with the Loeffler bacilli, we still may assume that heart weakness may be caused by some of the other germs, and therefore I do give large doses of alcohol in such emergencies, but only temporarily.

6. In nephritis alcohol can only do harm in large doses. Strümpell insists that acute alcoholic nephritis exists as well as chronic. Alcohol has a strong action on the epithelial cells of the kidneys, and therefore may occasionally be used to advantage in emergencies. Light beer has served me well in a few cases. On Jan. 1 1894, I was called to intubate a girl of five, then ill with "sore throat" for a week. A culture showed Loeffler bacilli. Two days later the child had a sudden convulsion and the temperature rose to 105° F. During the next twenty-four hours but one tablespoonful of bloody urine was passed. Nausea caused the child to even throw up cold water. Diuretin per rectum had no effect. In desperation I offered her beer, which she had never before tasted. She took it, retained it and lived on it for two days. Urine came and slowly improved. On the third day she took buttermilk, later on, milk, and she made a slow but complete recovery. Albumen persisted for a month, blood was found for two weeks. She was given no more alcohol after she took the buttermilk.

Knowing the effect of large doses of alcohol on the healthy kidney epithelium, and knowing the frequency of diphtheric nephaitis (to which knowledge of the profession at large seems to have been helped but recently, through the introduction of the antitoxine), we may well ask if routine alcoholisation in diphtheria may not cause great mischief? In the nephritis almost invariable accompanying severe gastro-enteritis in young children, usually never looked for, alcohol is out of place, as well as in post-scarlatina nephritis.

In conclusion, I believe that the amount of alcohol given to sick children by physicians (aside of occasional emergencies few and far between), is in direct proportion to their ignorance of the proper dietetic and hygienic management that their little patients are in need of.

Sequelae of Symphyseotomy.

Tissier (*Archives de Tocologie et de Gynècologie,*) exhibited recently at a French society a woman upon whom he had performed symphyseotomy six weeks previously. She was a multipara and rachitic. The conjugate was about three inches. Her previous labors had been severe. Labor was induced by Tarnier's bags and the forceps applied three times without result. Symphyseotomy was then performed. The hemorrhage was free. When the public bones parted a prolapse of the pelvic organs was distinctly observed. Delivery was accomplished with ease. There was troublesome tympanites about the third day. By the seventeenth day the symphsis was not consolidated and the public bones still slid on each other a little, consequently the patient could not walk long without feeling fatigued. A thrombus developed around the levator ani on each side during the puerperium, but both became absorbed. The child died when a few weeks old. The question as to the cause of the tympanites was raised at the society. Tissier believed it to be due to the prolapse of the uterus, which intercepted the free descent of the flatus. Fournel believed it to be due to temporary intestinal paralysis, as is frequent after abdominal section.

PERISCOPE.

IN CHARGE OF WM. E. PARKE, A.M., M.D.

MEDICINE.

Strychnine Delirium.

Those members of the medical profession who have employed caffeine very largely in the treatment of cardiac and renal disease have recognized that large doses of this drug, continuously administered for a considerable period, developed in certain individuals what has been popularly called "caffeine craziness." In other words, the full medicinal doses required by the condition of the heart or kidneys have also been sufficiently large not only to produce an increased activity of the brain, such as is seen when coffee is taken in large amounts, but also have gone farther than this, and by the very cerebral stimulation produced temporary insanity. Within the last few years the medical profession has been employing in certain states what may be considered as massive doses of strychnine in the treatment of failing repiration or circulation, and has obtained therefrom very good results. It having been found that these full doses of strychnine acted favorably, when given in an emergency, we have been tempted to continue their administration where the symptoms were relieved but temporarily, and, as a result, have oftentimes been pleased with their effect. On the other hand, a sufficient number of cases have been seen in which cerebral disturbance has followed these large doses to put us continually on the lookout for such untoward symptoms. As a rule, he who administers large doses of strychnine in an emergency is on the *qui vive* for some twitching of the muscles of the forearm or other portion of the body as an evidence of the physiological action of the drug. While we believe that these symptoms are commonly produced by a single administration of the remedy, we are also confident that its continued administration in full doses frequently fails to produce these evidences of heightened reflex activity, and in their place causes a more or less active delirium, in which the patient frequently refuses to take his medicine, or develops the delusion that his attendants are conspiring to poison him or do him some other injury.—*Thera. Gazette.*

Acetanilid in the Treatment of Malarial Fever.

At a meeting of the Philadelphia County Medical Society, Dr. Oscar H. Allis read a paper contributed by Dr. Benjamin Brodnax of Brodnax, La., in which the recommendation was made that acetanilid should be used instead of quinine in the treatment of chills and fever. Dr. Brodnax states that he has treated several hundred cases in this way and always successfully. If there is time before the chill, he gives from one-and-a half grains to two grains of calomel in one-quarter-grain doses half an hour apart; after which, whether the bowels have moved or not, from two to six grains of acetanilid, according to the age of the patient, are given twenty minutes or half an hour before the expected chill. Gentle perspiration with natural sleep usually promptly follow the administration of the drug and the patient wakens, entirely relieved, in about half an hour. Should this effect not be produced, a second dose of equal amount should be given half an hour after the first. If there is not time before the chill to administer the calomel, this may be deferred until after the acetanilid has been given and its effect has passed away.

The after-treatment consists of the administration of the following:

Diluted nitro-muriatic acid....1 fluid ounce.
Ferrous sulphate.....80 grains.
Mix, and allow to stand for twenty hours.
Dose—Ten drops in water three or four times a day.

Prognosis of Diabetes.

Dr. Arthur C. Jacobson has beencontributing a series of articles to the Brooklyn *Medical Journal* on Diabetes Mellitus. In speaking of the prognosis of this disease, he says: "Generally speaking, true diabetes is an incurable disease. Cures, however, have been reported, but it is probable that many such cases were of the transient or intermittent variety of glycosuria, occasionally observed in corpulent individuals given to overfeeding, or in those subjected to severe mental strain. This form is very amenable to treatment. Tyson, however, reports a case of true diabetes in a girl twelve years of age terminating in complete recovery, but it is to be born in mind that apparent recovery does not exclude the possibility of a fresh outbreak of the disease."

Influence of Cold Baths on Toxicity of Urine in Febrile Disease.

Dr. Ausset, an army surgeon (*Medical Week*), has been making extensive experiments in the effects of the cold bath upon urinary toxicity in infectious diseases, especially typhoid fever, scarlet fever, and measles. He finds that in all cases, the toxicity of the urine is greatly increased under the influence of cold baths. He attributes to this fact the excellent effects of Brand's method of treating febrile diseases by the cold bath, the temperature being lower and the course of the disease being favorably influenced by the increased elimination of the toxines produced by the specific microbes of the disease.

THERAPEUTICS.

Cocaine Cataphoresis in Neuralgia.

It is pleasant to have one's views on the treatment of neuralgia in superficial nerves corroborated by such experience as this of Dr. McGuire. Neuralgias in superficial nerves (such as branches of the trigeminus) are always best treated by cocaine cataphoresis, so far as the immediate relief of pain is concerned. This method is always the most satisfactory where the pain is due to a local lesion in the nerve and the neuralgia is not central.

The case instanced by McGuire was that of an adult man, with neuralgia of the inferior dental branch of the inferior maxillary nerve. After exhausting ordinary remedies in this case, he cut the nerve, and gave relief; but the pain returned some months, after in the lingual branch of the same trunk.

Mastication was so painful that he was compelled to live on liquid food. Swallowing, speaking, or moving the tongue in any way brought on violent paroxysms of pain.

The author goes on to say:

"I determined to try the effects of the cataphoric use of cocaine over the nerve as it passes to the side of the base of the tongue, and was induced to do this by remembering that my son, some months ago, had not only relieved, but permanently cured, several obstinate cases of neuritis by this method.

"I took the positive pole of a galvanic battery, covered it with a piece of absorbent cotton, saturated it with a 10-per-cent. solution of muriate of cocaine, and placed it in the mouth over the portion of the nerve which is the usual site of operative procedures, placed the negative pole on the external surface of the cheek, and passed a current of five milliamperes for a period of five minutes. The pain was instantly relieved, and I must confess, much to my surprise, did not return for twenty-four hours, a period much longer than would be required for the effect either of the electricity or of the cocaine to wear off."—*Gaillard's Med. Jour.*

Hot Saline Baths in Infantile Paralysis.

In the chronic stage of infantile paralysis, the mother should be instructed to bathe the affected parts daily with a hot solution of common salt. The solution should be of the strength of three or four ounces of salt to a quart of water, and the application should be as hot as can be borne, and should be followed by vigorous rubbing of the affected parts with oil. The mother should also be instructed to flex all the joints completely, taking care to antagonize any tendency to equinus, or equino-valgus or varus, which may occur. The writer recently operated upon a case in which the most extreme degree of equinus possible had resulted from neglect of this precaution. Both feet were affected. In one foot the equinus was complicated with varus, and in the other with valgus. These cases are often neglected, to the great detriment of the patient. Applications of electricity, systematic massage, and skillfully directed gymnastics are of great value in these cases, and should be employed as soon as the lesion is discovered, or at least as soon as the acute symptoms have disappeared. In some cases orthopædic apparatus is necessary to prevent serious deformity. Great results can often be accomplished in these cases; even the most unpromising symptoms may sometimes be made to yield surprising results by persevering treatment.—*Ed. Mod. Med.*

Blood Alterations in Ether Anesthesia.

In seeking for the cause of anesthesia in ether inhalations, Dr. J. C. DaCosta gives, in the *Medical News*, the results of a series of cases carefully studied, in which he is of the opinion that not only the direct action of the ether on the nerve elements, but an alteration in the composition of the blood, causes this unconsciousness. His conclusions are:

1. Etherization produces a marked diminution in the hemoglobin of the blood.
2. The red corpuscles and the hemoglobin are especially affected in blood previously diseased, in such conditions, for instance, as anemia.
3. Irregular reports are due to faulty observation, to the presence of altered hemoglobin in the blood, to the faulty aberration as to color of a Fleischl instrument or to taking the blood before anesthesia is completed.
4. The white corpuscles show irregular changes which are not characteristic, and exhibit variations not more pronounced than would be found in the same number of samples of normal blood on different examinations.
5. Age does not apparently influence the results.
6. Ether-pneumonia may possibly be due in some instances at least, to the action of intense cold upon the lungs, produced by the action of ether-vapor.
7. Edema of the lungs may arise from contraction of the pulmonary capillaries, thus producing a loss of *vis a tergo* and damming up of blood in the veins. Furthermore, the same condition may produce sudden paralysis of the heart.
8. The often-quoted observation as to the effect upon the hemoglobin of shock and hemorrhage requires enlarged repetition upon human beings before the statements can be unreservedly accepted that hemorrhage causes a great fall in the amount of hemoglobin, but that shock does not affect it.
9. The chilling of the blood-stream may be responsible for the nephritis that occasionally follows etherization.
10. Prolonged anesthesia profoundly deteriorates the blood and strongly militates against recovery; hence rapidity of operation is most desirable.

Alumnol.

Chotzen (*Berlin Klin. Woch.*) has investigated the therapeutic action of alumnol, a substance discovered by Filehre of Breslau. Alumnol is an aluminal salt, which contains about fifteen per cent. silver and five per cent. aluminium. It is a fine white powder, very soluble in water, in glycerine and in

warm alcohol. It is insoluble in ether. Henz and Leibrecht have already reported on its physiological action, and have shown it to be a harmless, odorless and antiseptic astringent. The author has used it in more than three hundred cases. It was found curative, when applied pure to soft chancres and abscesses, mixed in the proportion of ten to twenty per cent.; with inert powders in balanitis, erotions, moist eczemas, etc. One to five per per cent. solutions were used in moist and papular eczemas, acne of the face, boils, and urethritis. Two and a half to ten per cent. solution in alcohol was used for the treatment of eczema, urticaria, sycosis, favus, psoriasis of the head and face; and two and a half, five, ten and twenty per cent. lanolin ointment for eczema, seborrhœa capitis, psoriasis and favus. Alumnol varnishes were used in papular and squamous eczemas. It was found that alumnol was efficacious in acute superficial inflammatory affections of the skin, as well as in chronic processes in which the inflammation was deeper; and in parisitic diseases (under which head the author includes erysipelas, favus, lupus, soft chancre, erosions and gonorrhœa); and in acute and chronic inflammations of the mucous membrane.

Changes in the Respiratory Organs in Carbolic Acid Poisoning.

Leon Wachholz reports two cases of suicidal poisoning with carbolic acid in which post-mortem examination showed, among others, changes in the respiratory organs. That carbolic acid occasions certain anatomical changes in these organs has long been known, but the explanation of such changes, however, has been unsatisfactory. To elucidate the question the author undertook a series of experiments on animals, from which he draws the following conclusions:

1. Carbolic acid is absorbed into the blood, whence it is violently eliminated by the kidneys, occasioning necrobiotic changes in those organs.
2. It affects the respiratory organs in the same manner as preparations of mercury do the bowels.
3. The course of the poisoning in man and warm-blooded animals differ in that, in the latter the period of excitation predominates, while coma and paralysis develop in man at the outset.—*Przeglad Lekarski.*

Water in the Treatment of Neuralgia.

Dr. Buxbaum first called the attention of the profession to this mode of treating neuralgia. He thinks that the hydrotherapeutic treatment of this disease has hardly received the attention which it deserves. In neuralgia of rheumatic origin it acts by inducing increased blood supply to the affected parts, and in the neuralgias following upon the infective diseases or due to intoxication by mercury or lead, it promotes the elimination of the poison.

He reports that in 83 typical cases of neuralgia this treatment was unsuccessful only in 10 per cent., whereas 60 per cent. were cured, and the remainder considerably relieved. The alternate application of heat and cold is most to be recommended. The patient is exposed to high temperatures, and afterwards cold applications are made. The alternating Scotch douche is particularly of service. Recent neuralgias may often be cut short in this way. Patients with sciatica treated without effect by various therapeutic measures, even including nerve stretching, have been cured in a short time by this method. If the neuralgia persists it is nearly always due to some irremediable cause, with the exception of some few cases open to operation. If a remission occurs after the treatment has begun, it shows the neuralgia is curable, and is therefore of prognostic value. In trigeminal neuralgia hydrotherapeutic measures applied to the whole body are the most suitable. Of course other indications should be attended to, such as anæmia, malaria, etc.—*Charlotte Med. Jour.*

Difference in the Actions of Pepsin and Pancreatin in Digestion.

Extensive experience has proved to the author that pepsin is indicated only in a very small number of cases of indigestion. If there be an insufficiency of ptyalin in the saliva, starchy substances will reach the stomach without being digested; pepsin will have no effect on it, whilst pancreatin—which digests twenty-five times its weight of starch—completely saccharifies it.

In stomachal digestion, pepsin can be active, but it is absolutely indispensable that it be in the presence of an acid gastric juice, which, in the author's opinion, occurs very rarely. If the pepsin be replaced by pancreatin, giving a dose of ½ to 1 gramme before meals, the latter, by virtue of its power of peptonizing thirty-five times its weight of albumin, will secure rapid and complete digestion of the albuminoids in the meals.

The action of pancreatin on fats cannot be doubted, since the pancreatic juice which contains it possesses the property of emulsifying and decomposing them. But it is necessary, to maintain its emulsifying power, that it pass the stomach without being acted upon by the gastric juice; it must, therefore, be protected against the acid of this juice.

The author states that in patients who had taken pills containing iodides with pancreatin immediately after their meals, the urine and saliva began to give an iodine reaction only six hours after the ingestion of the pills. Pancreatin contains three ferments: Amylopsin, which saccharifies starch; trypsin, which peptonizes albumin; and steapsin, which emulsifies and decomposes all fatty substances. Precreatin, therefore, acts on all food by the simultaneous action of its three constituents, and thus secures complete digestion. Moreover, it is indicated in enterocolitis; and in gouty persons, it is said to improve nutrition by modifying the products of digestion, and to cause cessation of attacks of gout and of glycosuria.—*Dr. Gombault* (*Gaz. des. Hop.*)

ORIGINAL ARTICLES.

CLIMATIC CAUSATION OF DISEASE.*

I. M. CLINE, M. A., M. D., GALVESTON, TEXAS.

This subject, while one of the broadest in its scope, and dealing directly with the physiological effects of the medium in which we have our existence, is perhaps the least understood of all the questions bearing on the etiology of disease, and has received from investigators the smallest amount of attention.

The reason for this is at once obvious, for there are many barriers to the study of this question. It is a difficult task to collect statistics from which to study the causes of disease, especially in sufficient numbers to give reliable results. The causes of many diseases, however, can be studied from mortality statistics, of which there is a vast amount accessible. Where the disease is one attended with occasional fatality, the deaths furnish a basis for the study of this subject. When large populations are considered it is safe to assume that on an average the daily, yearly or monthly deaths from a disease will bear a constant proportion to the cases of sickness from that disease, and such being the case, very accurate studies can be made of the causes of those diseases from which deaths occur, for whatever aids in the cause will show its effects in the latter stages as well as in the first; and it follows that deaths should be more frequent with, or immediately following, those conditions of climate which tend to cause the disease. There are, however, objections to offer to this method, such as mistakes in the diagnosis of diseases and the irregularities in nomenclature. This, it is true, makes the question more complex and difficult to study, but results of sufficient accuracy can be obtained to lead to correct conclusions as to the relation of climate to the cause of disease. To accomplish even small results in this line requires years of hard labor, and that the investigator have both medical and meteorological training.

It is gratifying to note that some of our leading medical institutions are introducing meteorology in their carricula, and it certainly cannot be many years until medico-climatology will be recognized as of such importance that all first-class medical institutions will accord it a chair in their faculties.

We are taught that in the study and practice of medicine the end in view and the object to be attained is a knowledge of how to prevent, relieve and cure disease. The application of this admonition consists not only in the administration of medicines, but also in a thorough knowledge of all matters which influence the various morbid conditions to which the

*Read before the Texas State Medical Association in the Section on Practice of Medicine, April 23, 1895.

human economy is liable. There can be no doubt that of the many factors which contribute to help or hinder physical well-being a very large share must be attributed to climate understood in its widest sense, particularly to those conditions of atmosphere and soil which are constantly operating upon the human organism by day and night. The air breathed, its temperature, vapor of water, purity and pressure; the amount of sunshine received; the character of the winds; the nature of the soil; all have a potent influence upon the organism in health in causing or preventing disease, and still more potent is its influence upon the organism in its unstable and sensitive condition when already the subject of disease.

The position occupied by the physician in this respect is one of great responsibility, and notwithstanding the vastness of the subject it is attracting the attention of leading medical practitioners in all parts of the country. It frequently falls to the lot of the physician to select a climate for a patient, which determines whether or not life shall be prolonged and suffering relieved, and a mistake is fatal. During the ten years which I have been connected with the Weather Service in Texas, I have received a large number of communications from physicians in the populous centers throughout the country, looking for climates in which to locate their patients to the best advantage. Information concerning the prophylactic and therapeutic properties of this or that climate is being diligently sought. The conclusions which have been reached in regard to these properties of climate have, until within the past few years, been altogether empirical, and still are so in a great measure in so far as the profession is advised.

However, definite conclusions have been reached relative to the effects produced by climate on some of the more important diseases. By the study of the effects of different climatic conditions and changes on the different organs, from what we know of the physical effects produced by such conditions and changes, and the study of the relation of diseases to these conditions by the correlation and study of the vast amount of accessible facts, results are reached which are fast paving the way from empiricism to logical and sound conclusions. Some valuable though limited investigations relative to the climatic distribution of pulmonary phthisis in Massachusetts were made by Dr. H. I. Bowditch*, of that State, some years ago, from which he reached the conclusion that the disease was more frequent in low, damp localities than on higher land. Similar investigations† were made a few years later by Dr. G. Buchanan, of England, relative to the distribution of the same disease in that country, and he arrived at conclusions similar to those of Dr. Bowditch. It remained for Dr. H. B. Baker, Secretary of the State Board of Health of Michigan, to commence the study of the relation of climatic conditions to the cause of certain diseases, and while his work is devoted to the seasonal relation which exists as the cause, his results are of great value.‡ I have gone more minutely into this question,§ and have investigated the relation between the causation and fatality of certain diseases and weather changes which take place from day to day, as these appear to be of greater importance than the seasonal changes, on account of their suddenness and frequency which shocks the system even when in health; and I have also studied the causes for the climatic distribution of diseases.

To ascertain the climatic causation of disease, the physical effects produced by known climatic conditions and sudden changes in the weather on the different organs of the human economy must be understood, as well as the climatic influences which produce these effects. The Weather Bureau keeps the climatic record for nearly every locality, and with these conditions known, and also a knowledge of the diseases which prevail, the desired results can be obtained. Congress has made appropriations for investigations pertaining to climatology and sanitary science for the entire country‖, and there is no doubt but that much will be accomplished in this direction in the near future.

---

*Med. Com. Mass. Society, Vol. X., No. 11, 1862.

†Tenth Report of the Officer of the Privy Council, 1867.

‡Annual Reports of the Mich. State Board of Health, 1886, et sequel.

§Special Bulletin No. 4, Texas Weather Service August, 1894.

‖An Act making appropriations for the Department of Agriculture for the fiscal year ending June Thirtieth, Eighteen hundred and Ninety-six; Weather Bureau, general expenses.

Temperature and moisture conditions of all climatic factors play the greatest parts in determining the healthfulness of a locality. The purity of the atmosphere is also an important factor, and one which must be kept constantly in mind. It is only the general relative purity of the air which makes this condition second to the preceding ones. The purity of the air for low levels depends in a great measure on the source from which the winds are derived. If they are continental they contain more or less impurities at all times; while, if they are oceanic, they contain chlorine and other antiseptic properties. The purity of the atmosphere increases rapidly with an increase in elevation. The amount of sunshine is of great importance in this respect.

In the investigation of this question there are some physical deductions concerning the capacity for moisture of the atmosphere at different temperatures, which must be kept in mind. From the meteorological tables of Guyot,* it is ascertained that a cubic foot of air at a temperature of Zero (Fahrenheit) can contain only 0.5 of a grain of vapor of water; at 32 degrees it can contain 2.13 grains; at 65 degrees it can contain 6.8 grains; at 95 degrees it can contain 17.14 grains; while at 98.5 degrees—the temperature of the body—it can contain 18.96 grains, nearly nine times the quantity which can be contained at a temperature of 32 degrees. Air at a temperature of 32 degrees and saturated with moisture (that is with 100 per cent. relative humidity), contains only one-fourth of the quantity of vapor of water which exists at 50 per cent. of saturation with the temperature at 95 degrees. Evaporation increases with a rise in temperature much more rapidly than it does with a decrease in moisture, which is due to the rapid increase in the capacity for moisture of the atmosphere with the increase in temperature as just noted. Evaporation from external surfaces of the body under average conditions carries off from the system through the skin a large amount of organic matter and water; such being the case a sudden fall in temperature, or an increase in the amount of moisture not accompanied by an increase in temperature, checks this action and increases the labors of the respiratory system, the kidneys and other eliminative organs, which, through any predisposition to disease or temporary weakness, often causes serious diseases. Any sudden weather changes are unfavorable to the successful treatment of most diseases, while in a few certain changes prove favorable. Decided change in temperature excites the nerve centers and, in exciting the vaso-motor center, disturbs the vascular system and causes the capillary vessels to become gorged and paralyzed, which is a cause for inflammation in the parts so affected.

Conduction of heat from the body to the atmosphere increases with the increase in the amount of vapor of water, and is an important factor in studying the effects of the temperature of the atmosphere on the body, both externally and internally. The range between day and night, and sun and shade temperatures produces marked effects on the human organism. These effects are most pronounced during the summer months when the differences between day and night temperatures, especially where there is much radiation, often amount to 50 or 75 degrees, and that between sun and shade temperatures amount to 40 or 50 degrees. After fatigue in the sunshine, when night comes on, or on retiring to the shade, a decided change in temperature is experienced. The difference shown by the thermometer between day and night, and sun and shade temperatures is not all that is felt; this is materially augmented by conduction where there is considerable moisture, and to these are to be added the cooling effects of evaporation. When the body has been exposed and forced to adapt itself to a high sun temperature and is suddenly transferred to a medium, with the temperature 50 to 75 degrees below the sun temperature and the organism is at rest, it is subjected to rapid cooling by the conditions just mentioned, which contracts the capillaries of the skin, interrupts the blood in the proper performance of its functions, and results in local or general congestion.

The effects which are produced by the differences in the capacity of air at different temperatures for vapor of water, are most marked on the respiratory system, for here we have not only to consider the external evaporation but, in some climates, the excessive internal evaporation. Air at moderately low tempera-

*Guyot's Meteorological Tables, 1859. pp 92-93.

tures (even not below 32°) when inhaled has its temperature increased to that of the body, 98.5°, or at any rate to within three or four degrees of this, and its capacity for moisture is greatly increased on account of the rise thus brought about. With an average of twenty respirations per minute (28,800 per day) and the amount of air taken into and expelled from the lungs at each respiration, 21 cubic inches, we have a total of 350 cubic feet of air used in respiration daily. Physiologists are generally agreed that the quantity of vapor exhaled from the lungs depends greatly upon circumstances, such as the rapidity of respiration, dryness or humidity of the atmosphere, and the activity of the pulmonary circulation. It is apparent, however, that the quantity of water given off from the system in the form of vapor in excess of that received during respiration depends almost entirely upon the temperature of the air inhaled. Assuming that the air leaves the body at a temperature of 98.5° and is saturated with moisture, it would carry from the lungs 6,636 grains of water in the form of vapor, daily. The important point in this connection is the excess in the amount of water exhaled from the lungs over that inhaled. For example, take a locality with the average daily temperature 32° during the cold months (there is a large area of the United States with an average daily temperature below this during some of the winter months), and the average relative humidity 75 per cent. (which is rarely exceeded), each cubic foot of air would contain about 5.1 grains of vapor. The amount of water taken into the lungs by respiration during a day under these conditions would be 1,758 grains, while the amount exhaled, 6,636 grains, shows an excess daily of 4,851 grains of water given off from the system through respiration over that received. The excess becomes greater as the temperature goes lower and less as it rises, while the per cent. of moisture remains constant. To furnish the complement of water between the amount inhaled and that exhaled, causes rapid evaporation to take place from the lining mucous membrane of the air passages and air cells of the lungs, where such weather prevails. The fluids from the pulmonary circulation, which normally keep the lining membrane of the lungs moist, contain more or less of the non-volatile salts carried in solution in the blood.* These salts are left as a deposit from the water carried out of the lungs during respiration, in quantities depending upon the amount of salts in the blood at the time, and the extent of the evaporation which takes place. Simple physical deductions give these conclusions, but they have been substantiated by analysis.†

In this connection we have the established fact that albumen will not pass through an animal membrane toward pure water, while it will pass to a solution of salt; and the more rapid the movement of the fluid the greater is the amount of albumen which passes through to the salt solution.‡ This being the case it results, when there is a deposit of salt on the mucous lining of the lungs, that exudation of albumen into the air passages and air cells of the lungs takes place.

Such I am inclined to believe are the exciting causes of pulmonary diseases, as they are favorable for the lodgment of the germs to which most of the diseases of the respiratory system are due; and it may yet be established that the lodgment and growth of these germs depend upon the extent of these conditions in the lungs.

In my studies of the relation of sudden changes and abnormal departures in temperature to the several diseases, from records in some instances covering twenty years I have obtained some interesting results. From the diseases which I have studied separately, which embrace more than a hundred and twenty-five, the following gives the greatest number of deaths and also shows a decided increase or decrease in mortality with certain temperature conditions with which we come in contact every day.

Deaths from pulmonary phthisis are 25 per cent. less on days with minus, and 38 per cent. greater on days with plus changes in temperature than on days with stationary temperature; and are 33 per cent. and 20 per cent. greater, respectively, on days with abnormally high and abnormally low temperature, than on days with normal

*The Causation of Pneumonia by Dr. H. B. Baker, Lansing, Mich., 1888.

†Medico-Chirurgical Transactions, Vol. XXXV. London, Eng., 1852.

‡Dr. Felix Hoppe, Virchow's Archives, Vol. IX. 1856, pp 245-268.

temperature. The greatest number of deaths from this disease always follows the occurrence of the lowest temperature.

Deaths from pneumonia are 75 per cent. greater with any decided change in temperature than with stationary temperature; and are 44 per cent. and 78 per cent. greater, respectively, on days with abnormally high and abnormally low temperature than on days with normal temperature.

Bronchitis gives a slight increase in deaths on days with minus changes in temperature; and they are 67 per cent. and 117 per cent. greater, respectively, on days with abnormally high and abnormally low temperature than on days with normal temperature.

Deaths from congestion of the lungs are 86 per cent. greater on days with abnormally low temperature than on days with normal and abnormally high temperature; and are 43 per cent. and 79 per cent. greater, respectively, on days with decided fall and decided rise in temperature than on days with stationary temperature.

Deaths from membraneous croup are 166 per cent. greater with either decided rise or decided fall in temperature than on days with stationary temperature; and are 200 per cent. greater with any abnormal temperature than on days with normal temperature.

In all diseases of the circulatory system quite a similarity is found in their relations to temperature conditions. Deaths are 100 per cent. and 55 per cent. greater, respectively, with sudden rise and sudden fall in temperature than on days with stationary temperature; and they are 10 per cent. greater on days with abnormally high temperature, and 10 per cent. less on days with abnormally low temperature than on days with normal temperature.

Deaths from the diseases of the blood are 50 per cent. greater on days with decided rise in temperature, and 30 per cent. less on days with decided fall in temperature than on days with stationary temperature; and are 50 per cent. greater on days with abnormally high temperature than on days with normal or abnormally low temperature.

From diarrhœal diseases deaths are 52 per cent. greater on days with decided rise in temperature, and 40 per cent. less on days with decided fall in temperature than on days with stationary temperture; and are 25 per cent. and 10 per cent. greater, respectively, on days with abnormally high and abnormally low temperature than on days with normal temperature.

From diseases of the kidneys deaths are less frequent on days with rising temperature and on days with abnormally high temperature, than on days with stationary normal temperature; are 158 per cent. greater on days with a decided fall in temperature than on days with stationary temperature; and are 80 per cent. greater on days with abnormally low temperature than on days with normal temperature.

Deaths from diseases of the nervous system are 30 per cent. and 18 per cent. greater, respectively, on days with a decided rise and on days with a decided fall in temperature than on days with stationary temperature; and are 52 per cent. greater and 30 per cent. less, respectively, on days with abnormally high and on days with abnormally low temperature than on days with normal temperature.

Deaths from typhoid fever are 38 per cent. greater and 10 per cent. less, respectively, on days with decided rise and on days with decided fall in temperature than on days with stationary temperature; and are 28 per cent. greater and 25 per cent. less, respectively, on days with abnormally high temperature and on days with abnormally low temperature than on days with normal temperature.

From malarial diseases deaths are 40 per cent. and 10 per cent. greater, respectively, on days with decided rise and on days with decided fall in temperature than on days with stationary temperature; are 30 per cent. greater on days with abnormally high temperature, and are 30 per cent. less on days with abnormally low temperature than on days with normal temperature.

Deaths from diphtheria are 75 per cent. and 135 per cent. greater, respectively, on days with a decided rise in temperature and on days with a decided fall in temperture than on days with stationary temperature; and are 150 per cent. and 68 per cent. greater, respectively, on days with abnormally high temperature and on days with abnormally low temperature than on days with normal temperature.

Deaths from old age are 50 per cent. greater on days with plus changes in temperature than on days with minus changes in temperature and on days with stationary temperature; and are 30 per cent. greater

on days with abnormally high temperature than on days with either normal or abnormally low temperature.

In considering the physical effects produced on the organism by the more important climatic conditions and the known relationships between climatic conditions and diseases, I have divided climate into three general classes, viz: Low, damp, *cold* climates; low, damp, *warm* climates; and high, dry climates. These features of climate are determined by latitude, by proximity to large bodies of water and by altitude.

A low, damp, *cold* climate is one where the altitude is small, and is of relatively high latitude; the temperature in winter is comparatively low, and the per cent. of moisture (saturation) is relatively great. On account of the low temperature in winter the amount of vapor of water present is small, which causes excessive evaporation from the mucous lining of the lungs as a result of the increased temperature of the air during the process of respiration. The relative humidity being high no evaporation of consequence takes place from external surfaces. The winds are generally continental and give an atmosphere containing more or less impurities. Sudden changes and abnormal departures in temperature are either more frequent or of greater effect in this character of climate than in the others. The diurnal range in temperature is generally great, and the conduction of heat from the body through the moisture medium, particularly during the warm season, is marked and adds to the effects of the temperature changes, and the differences between sun and shade temperatures reach their maximum. These conditions tend to cause certain diseases and to increase the fatality of others.

The excessive evaporation from the mucous lining of the air-passages and air-cells of the lungs, with limited external evaporation as a result of the low winter temperature and high relative humidity of this climate, combined with the sudden changes and abnormal departures in temperature, give the conditions which cause, or favor the cause of diseases of the respiratory system and, consequently, we find pulmonary phthisis, pneumonia, congestion of the lungs, pleuritis, bronchitis, and asthma more frequent in this climate than the others. Diseases of the kidneys are frequent, due to the high degree of saturation with vapor of water constantly present, and also to the frequency of sudden falls in temperature, either of which reduces the amount of water and organic matter eliminated through the skin, the former constantly and the latter spasmodically, and hence increases the elimination through the kidneys.

It can hardly be claimed that typhoid fever is caused by climatic conditions, yet these conditions either favor or prevent the development of the germ of the disease, and its fatality is increased or diminished by climatic changes. It is a summer disease, occurs at a season of the year when decided changes in temperature are more frequently rises, and abnormal departures are more frequently excesses, neither of which conditions are favorable to recovery from this disease, and both favor germ development.

The decided rises in temperature in this climate are unfavorable to diseases of the blood, as mortality from causes of this character is least on days with stationary and minus changes in temperature, and greatest on days with rises in temperature and on those with abnormally high temperature. Diseases of the circulatory system are always greatest where the most frequent decided changes in temperature occur, which is in low, damp, cold climates. Diarrhœal diseases are almost confined to the summer, and are most frequent in this climate on account of the extreme changes in temperature experienced that derange the functions and bring about more or less congestion, which is a factor in causing these diseases. Nervous diseases are frequent in this climate as a result of the sudden changes in temperature and the diurnal range which excite the nervous centers. Diphtheria is a cold weather disease and is most frequent in this character of climate. Malarial diseases are almost exclusively confined to low, damp, *cold* climates. The differences in temperature experienced in summer, under the conditions which exist in this climate, cause congestion and interrupt the blood in the proper performance of its functions, causing fever. It is probable that the micro-organism found in connection with this disease is caused by the effects of these climatic conditions

on the circulation. Old age suffers under this climate on account of the sudden changes which it bears poorly. The impaired vigor of circulation, assimilation and excretion, which characterize advanced years, and the special maladies most frequent at that time of life, such as rheumatism, cardiac disease, and renal affections, are all augmented by this kind of climate. The diurnal changes in temperature are unfavorable to the aged.

Low, damp, *warm* climates are those where the altitude is small; are sub-tropical, and marine influences tend to keep the temperature uniform and to remain comparatively high throughout the year; and there is a constant large per cent. of humidity (which with the high temperature means a large amount of vapor of water). Sudden changes in temperature are infrequent, and the range between day and night, and sun and shade temperatures is small. In this climate the evaporation which takes place from external surfaces is small, as in the preceding climate, but as the temperature is high and the amount of vapor of water large, the increase in the temperature of the air taken into the lungs is small and consequently the increase in its capacity for moisture is small. The evaporation from the mucous lining of the lung is small; the residue of salts and the conditions favorable for the exudation of albumen are all lessened where the temperature during the greater part of the year is not far below that of the body and the per cent. of moisture is constantly great. This climate may have either prevailing oceanic or continental winds, and much of its sanitary characteristics depend on these. The meteorological features of marine climates, while they have many in common, some of the most important characteristics are determined by the prevailing winds and the latitude. Here the climate is charged to a greater or less extent, depending upon the amount of oceanic winds, with chlorine and saline matters which act in the capacity of strong antiseptics and disinfectants. As regards the physiological action of sea air upon the healthy organism, the marine climate is usually tonic, tending to promote the processes of nutrition and assimilation, and is at the same time sedative in character. It is the most exhilerating of all climates; and while it aggravates some diseases, is generally prophylactic. It is unfavorable to those suffering with diseases of the kidneys on account of the large amount of moisture constantly present, which throws the increased elimination of water and organic matter upon these organs; it however possesses advantages over the low, damp, *cold* climate on account of the less frequent decided changes and abnormal departures in temperature. The conditions which prevail in this climate may be summed up as, in a great measure, preventive in effect upon the diseases of the digestive organs, particularly when the trouble is with the stomach and bowels, but where the liver is involved its effects are unfavorable, and its tendency is to cause diseases of this type. Cutaneous diseases are excited by the large amount of moisture charged with irritating salts; most cases of rheumatism are benefitted except when of an inflammatory character; pulmonary phthisis and other diseases of the respiratory system are not aggravated and, as a general rule, the small temperature changes and other climatic conditions are favorable to their treatment, the antiseptic effect of the chlorine is a potent factor, particularly in phthisis. The generalizations reached by Drs. Bowditch, Buchanan and others, to the effect that pulmonary phthisis is most frequent in low, damp localities, will not apply to this character of climate, for here we find a relatively small mortality from this disease, being only about one-half the average, as given by the best authorities, for the world.* This climate is beneficial to those who are debilitated from overwork or long continued strain apart from actual illness. The equable and bracing conditions are very favorable to young and growing children, and promote healthy and normal physiological development. The equable and moderate warmth, combined with its sedative influences and its properties of stimulating tissue change and the riddance of morbid deposits, make it very favorable for the aged, and life is prolonged far beyond the average under such a climate. I have found in my investigations in different climates that the number of people who die at advanced age is greatest in this character of climate. The conditions are

*Flint, Practice of Medicine, 6th edition, page 195, gives the average deaths for the world from this disease one-seventh of all deaths, while here it gives one-fourteenth.

such as to give the greatest vigor of circulation, assimilation and excretion, which the aged so much need, and which benefit the young.

High, dry climates are those of considerable elevation, and, on account of the elevation, are comparatively cold, particularly at certain seasons. Prof. Dr. J. Hann has determined that one half of the vapor of water of the earth's atmosphere is below an elevation of 6,000 feet, and eight-tenths is below an elevation of 10,000 feet.* The percentage of saturation is small; constant evaporation takes place from the external surfaces of the body, and a large amount of the non-volatile salts as well as organic matter in the system are carried away through the skin. This leaves the amount of salts which may be deposited on the mucous lining of the lungs considerably reduced, and besides this, even with low temperatures at high elevations, the evaporation caused by the increase in the temperature of the air inhaled, is not great because of the decreased capacity of the atmosphere for moisture in elevated regions. The organs of the body at high elevations adapt themselves to the conditions which surround them, and the capacity of the air inhaled for moisture is the same for the same temperature in the lungs as externally. Very little evaporation takes place from the lining membrane of the lungs, consequently there is very little if any deposit of the non-volatile salts; first, because of the excessive evaporation from external surfaces and, second, on account of the small internal evaporation. At high elevations there is at all times a large proportion of sunshine, with its deoxodizing and purifying effects. The conduction of heat from the body through the agency of moisture is at a minimum, even at the most extreme season. Decided changes in temperature are frequent and the diurnal range is generally large, but these are not magnified by the conduction of heat from the body as in low, damp, *cold* climates, and consequently the effects are at a minimum for the difference in temperature recorded. These climatic conditions present very few of the features which aid in the development of the diseases of the respiratory system; the conditions which favor the lodgment and growth of the micro-organisms in the lungs are not developed. This is the most favorable climate for the treatment of lung diseases, except in cases complicated with nervous troubles which would receive the greatest benefits in a low, damp *warm* climate of the extreme type. Diseases of the nervous system are aggravated by the decided changes in temperature which take place; diseases of the kidneys are in a great measure prevented by this climate; inflammatory rheumatism is generally improved. This climate is severe on old age on account of the sudden changes, and also the cold during the winter season which depresses those in whom the circulation is feeble; it develops a quick and nervous disposition in the young, and is unfavorable in cardiac troubles on account of the sudden changes and the large diurnal ranges in temperature.

In the middle-aged, when the system is in a normal condition the organs readily adapt themselves to climatic changes, but with the child and the aged, as well as those who are afflicted, changes of climate should receive careful consideration. Those who are subjected to conditions of climate which tend to cause disease should use every precaution to counteract the effects by proper clothing and diet, as well as the use of medicines, and also by avoiding the unnecessary exposure, more or less of which is witnessed every day.

Texas presents each of the three conditions of climate, in well defined types. The Northeastern portion of the state has a medium of the low, damp, *cold* climate. The immediate coast region presents the most perfect class of the low, damp, *warm* climate, where temperature changes and departures are slight, and rarely excessive or abnormal. The winds for ten months of the year are, except with occasional interruptions, from the Gulf of Mexico, and are from the same source for more than one-third of the time during the remaining two months of the year. There is a large amount of sunshine throughout this district, notwithstanding the heavy precipitation over the Eastern portion. The elevated regions of Western Texas are a good type of the high, dry climate, and a medium of this character of climate. All Texas, except the extreme West, has for eight months in the year a South wind from the Gulf of Mexico, which carries coolness and comfort at the very season when cool-

*Distribution of Aqueous vapor of the Atmosphere with increase of Altitude, Zeitschrift Qest. Met. Gessell, 1874, pp 193-200.. IX.

ness is most needed. *This, as already referred to in connection with the coast district, plays an important part in Texas climate; it gives the coast region one of the most perfect of climates in so far as healthfulness is concerned; it makes the Northern portion of the state one of the mildest of the low, damp, *cold* climates, and carries its salubrious effects far to the westward over the high, dry climate of that part of the state.

The distribution of diseases in Texas conform closely with the climatic conditions which influence the causation of disease, as discussed in this paper. Certain diseases of the respiratory system—pulmonary phthisis, pneumonia, pleuritis, bronchitis and asthma—are most frequent over the Northern portion of the state and decrease in concentric circles with the Northeastern corner as a center towards the Gulf and the elevated regions of West Texas. Diseases of the nervous system are most frequent over the Northeastern portion of the State; are some less over the Northwestern portion, and are least frequent over the immediate coast region. Diseases of the kidneys are most frequent over the Eastern portion, with a slight decrease Southward, and a marked decrease toward the West. Diseases of the digestive system are most frequent over the Northeastern portion, and decrease toward the South and West. Cardiac troubles are least frequent over the immediate coast section, and are most frequent over the Northeastern portion. Malarial diseases are confined to the Eastern portion of the State, but are seldom met with along the immediate coast.

HYSTERIA: CEREBRAL MANIFESTATIONS.

A. B. RICHARDSON, A.M., M.D.,† COLUMBUS, O.

Hysteria, misnamed, ill-defined, capricious and fleeting, has long been the subject of medical thought and inquiry, and yet to-day remains well nigh as imperfectly understood and as indefinite in its pathology as ever. Its nature, habitat, causation and successful treatment are still elusive—irritatingly, exasperatingly so. It is known to require for its production a certain type of organization, yet the physical features of this type, the physical basis of the disease, are still but vaguely outlined. In its essence it is a morbid state of the brain. It is essentially a morbid state rather than an active disease. It is an abnormal type of structure, a morbid functionating tendency, which either in itself may constitute the disorder or be superadded to active diseased processes. It has a connection with the uterus only in name, no further. The brain is its habitat and the nervous system the field of its active operations. The type of brain is its essence and furnishes its potentiality. Frequently if not inherited, it is found in individuals in whose organization there is a preponderance of the emotions, a want of mind equilibrium, a development of sentiment and the affective propensities at the expense of capacity to deliberate and choose. The disease is most active in the sex whose place in the economy of nature and whose work in the perpetuation of the race necessitates a preponderance of emotional development. It is seen perhaps twenty times more frequently in women than in men. All degrees of its development may, however, be seen in man and in as multitudinous variety. The type of such men is womanish in emotional development and lack of mature deliberation. It is most active at that age that is accompanied by the greatest degree of instability of nervous tissue, viz., the period of its most active growth and development, the period of pubescent and adolescent change. Fully 75 per cent. of all cases (Gowers) show the first active symptoms between the ages of ten and thirty years, and almost one-half of these begin between the

†Medical Superintendent Columbus State Hospital.

ages of fifteen and twenty years. Being in its essence a developmental peculiarity of the nervous system, and particularly of its central organ, the brain, it naturally has such relation to other disorders of the system as the nervous system has to other tissues and organs of the body. An imperfectly or peculiarly developed nervous system will almost inevitably be the cause, or at least the accompaniment, of imperfect development elsewhere.

The organs of reconstructive metabolism are often imperfectly developed in the same individual. The capacity to assimilate nourishment is limited, and there is a want of stored up reserves of nutritive material. This limited recuperative power is particularly marked in the central nervous system. The nervous elements are readily exhausted and do not readily recuperate.

So also are the organs of life reproduction often defective, and it is this fact that, to my mind, has led to the belief in some mysterious connection between diseases of the sexual system and the manifestations of hysteria, and that has ascribed the development of the latter to diseased conditions of the former. The truth is they are both evidences of the same dyscrasia, and, as the nervous system stands in the relation of a stimulant to the development of the other tissues and organs of the body, it is oftener true that structural defect in it is the origin of the structural peculiarity or deficiency in the sexual apparatus. Still oftener it is doubtless true that neither has any causative relation to the other. In fully one-half of all cases of hysteria there is no active disease of the sexual organs of any form or degree, and in many of the remainder the disease is an incidental one, one that has no causative relation to the hysterical phenomena, and whose removal will not materially influence their progress. In a few cases there is unquestionably reflex irritation from local disease here and elsewhere, whose removal may very favorably modify or wholly remove active hysterical phenomena, but these are, after all, the exception and not the rule. Laryngeal catarrh may accompany and influence the development of hysterical aphonia, a hysterical joint may be the outgrowth of arthritic inflammation, and so may hysterical symptoms of the sexual system be accompanied and even determined in character by gross disease in some part of this system, but it would be just as philosophical and just as effective to attempt to cure the hysterical state, of which purely functional aphonia is the expression, by ablation of the larynx, as to hope to cure it by removal of the uterine appendages when its manifestations are seen in functional derangement alone of these organs.

The brain manifestation of hysteria may be divided into two general classes. The first is that class in which the brain disorder is simply a predisposing but necessary factor in the development of the phenomena of the disease. The active symptoms are alone seen in disordered function of some other organ. There is a nervous dyspepsia, a hysterical joint, aphonia, ovarian tenderness, cardiac disturbance, or some disordered function of some special sense. In these the active symptoms are the disorder of the special organ, but the primary and essential element in the development of the disease is, after all, the peculiar brain state of the individual. In this sense the hysterical manifestations of the brain include all hysterical manifestations in all other organs, and, strictly speaking, there can be no hysterical symptoms of any organ without a morbid brain condition accompanying it.

Disorders of the special senses, anesthesia or hyperesthesia of the nerves of smell and hearing especially; sudden blindness, contraction of the visual field, variations in the color sense, loss or perversion of taste, or actual hallucinations of these senses; hyperesthesia or anesthesia of the fifth pair, face ache, tic convulsif, affections of the vagus, spasm or paresis, aphonia, spasm of the glottis, accelerated or diminished respiration, loss of speech, palpitation, disorder of digestion, esophageal spasm or paresis, vomiting, local anesthesias or hyperesthesias over various areas of the body, joint contractures or joint pains, paralysis of spinal origin, ischuria or polyuria—this is a simple enumeration of a few of the forms that these secondary symptoms may take. In the limits of this paper we cannot do more than partially enumerate them. The chief point to remember is that these may be purely hysterical or be complicated with actual organic disease. In the latter case the local disease probably determines

the direction of the hysterical manifestations, but does not originate the state of the brain of which they are the local expression. In every such case, however, all disease should be looked for carefully and every test of its presence exhausted. Never dismiss any case with the assumption that it is nothing but hysteria, because hysterical symptoms are present. The type of brain is one feature to be considered, the presence or absence of organic local disease superadded to this is another element just as important to the well-being of the patient. They may coexist, and the presence of of one should never lead you to exclude the other.

We turn now to the second division of the subject, viz., hysterical manifestations limited to the brain functions directly. These may be divided into two classes, the psychic and the somatic phenomena. The former are probably more frequent and more prominent, although the latter accompany many forms of brain disease. The psychic phenomena accompany many forms of mental disorder. They are almost uniformly present in pubescent and adolescent insanity, often in the insanity of pregnancy and of the parturient state, and in all forms complicated by sexual perversion or excitement. The hysterical manifestations are superadded to the insanity, and by no means constitute the disease. Time after time I have found it necessary to correct the impression that because hysterical symptoms were present the disease was simple hysteria, and within the patient's control. Mental derangement does seem in some instances to grow out of the hysterical brain manifestations by gradual steps where it did not before exist, and the dividing line between them is sometimes hard to determine. There is no rule by which the question can be decided. The point where a structural peculiarity develops into active disease, when we have nothing but the disordered function to guide us, is hard to determine. In hysteria major there is always a time during the progress of the fit when the patient is unquestionably insane, although temporarily so. There are often hallucinations and delusions, delirium with maniacal violence and storms of emotion. Acute melancholia is not infrequently complicated by hysterical phenomena, especially when occurring in young people, and it is well to bear this in mind. I have known suicidal impulses to be overlooked because the patient was believed to be simply hysterical. Hypochondriacal melancholia is very frequently accompanied by hysterical symptoms, and it is often extremely difficult to differentiate the symptoms of the two disorders and to refer each class to its proper origin, to distinguish those arising from the peculiar brain state from those due to actual local organic disease. Delusions relating to particular organs or functions may have an origin in actual organic disease of these organs, and yet the patient may much exaggerate the consequent disorder, magnify its importance and present the well-known features of the hysterical state. The self-consciousness of the hypochondriac is very similar to the self-absorption of the hysterical, and it is often impossible to distinguish between them. Speaking generally, we must look for the proof of hysteria in the state of the individual outside of the symptoms connected with the local disease. The fact that hysteria is a general state rather than a local disease will assist greatly in the indentification of its symptoms in all forms of mental disorder.

Outside the domain of strictly psychic disorder there is scarcely a disease of the general nervous system that hysteria may not complicate. As the patient approaches puberty, infantile hemiplegia, cerebral tumors, tubercular meningitis, multiple neuritis, chorea and epilepsy are frequently complicated by such well-marked hysterical phenomena as aphonia, phantom tumor and hysterical convulsions. This fact renders a correct diagnosis extremely difficult in some cases, and it is only by comparing the symptoms present with the evidences of the organic basis for them, testing their reasonableness and regularity and putting them to the proof, that the correct conclusion can be reached.

It cannot be necessary to discuss before this society the well-known symptoms of hysteria. They are either continuous or paroxysmal. They simulate every known disease and usually pattern themselves after such as are within the experience or observation of the patient affected. Imitation is one of the chief sources of the phenomena of the disorder, and faulty imitation is our chief diagnostic weapon. Inconsistency at some point in its manifestations with what they pretend to be is

their predominating characteristic. The rationality of their evolution must be the test of their character, and we must therefore call to our aid every law of the symptomatology of the known organic diseases and compare these phenomena with them. These laws must be our arbiter.

The pathology of hysterical manifestations of the brain, as has already been said, is very indefinite. It is, however, an interesting question, and, in the light of recent investigations into brain histology and the pathological anatomy of the acute insanities and of the study of the fatigue of nervous elements, it is beginning to assume a basis a little more definite than mere conjecture. At the risk of incurring the ridicule of our surgical friends, who believe only what they can see and feel, or think they do, I shall attempt an outline of my idea of the pathology of this uncertain symptomatology.

The doctrine of the neurons, as the essential anatomical basis of all nerve and mind activity, is becoming as well established as we can well hope such a difficult problem as the relations of psychic phenomena to physical elements to admit. Neurons are the true nervous elements in nerve tissues, and are made up of nerve cells and their connections. These are grouped into complex structures by association and commissural fibres, forming "groupings and clusters of cells, complexes of associated unilateral and bilateral clusters," as they have been termed.* Bear in mind, now, that this is not theory. The researches of Golgi and Ramon y Cajal, of Andriezen, Bevan Lewis and Batty Tuke, of Meynert, Obersteiner Fritsch and Hitzig have fully demonstrated the anatomical relations of the nervous elements as far as we shall attempt to describe them here.

The brain cortex is divided dynamically and functionally, rather than by the shape or size of cell elements, into three or four layers; the first, immediately beneath the pia mater, is the molecular; the second the ambiguous; the third the layer of large pyramids, and the fourth the polymorphous. The molecular layer has risen much in importance through recent investigation. In Meynert's time it was supposed to be composed in great part of basis substance and connective tissue. Now not fewer than ten different structures can be discovered in it. With the ambiguous layer beneath, it receives the distribution of the terminal filaments of the upward projection system, the sensory fibres from the special senses, the integument and the soma in general, coming, of course, through the filet, the olfactory and optic radiations, and the sub-centers of cell elements in basal ganglia, bulb and cord. On the other hand, the apical tufts from the large pyramids of the third layer beneath reach upwards, and spreading out encompass the nervous elements in these two layers from below, while the basal processes of these large pyramids are connected with discharging lines outward. This anatomical basis, when comprehended in all its complex detail, affords ample mechanism for all forms of nerve activity that result in movement and conduct. The complexes of cortical neurons are so disposed as to receive all the incoming nerve currents of sensory origin, and to "elaborate from these sensations still more complex," ultimately "attaining to such physical states as we denominate cognition and recognition, comparison, discrimination and judgment, and which finally issue as the reactions of conduct."* Andriezen, an assistant medical officer at the West Riding Lunatic Asylum, in England, has recently given a series of demonstrations of anatomical and pathological specimens from slides prepared by himself that fully corroborate these statements. Clouston, medical superintendent of the Royal Edinburg Asylum, Scotland, has also presented a most interesting series of slides showing the incipient cell and vessel changes in the primary stages of mental disease and in those more advanced. The forms of disease in which these were found were also described, and a rational relationship established between symptoms and pathological change. For instance, the primary change in the brain cell is shown by a swelling and an increase in the staining of protoplasm, nucleus and processes by the reagent, and these changes are connected with the stage of increased cell activity, as in the incipient stage of paresis or epilepsy. As the pathological process advances, the cell shows pigmentary or granular degeneration, diminished staining of protoplasm, nucleus and processes, and a complete de-

* Andriezen, Journal of Mental Science, October, 1894.

*Andriezen, Brain, Winter, 1894.

struction of the more delicate of the latter, and these changes are connected with such symptoms as amnesia, incapacity for attention, easily induced fatigue, insomnia and muscular weakness and tremor.

The theory of normal fatigue, psychically meant, and cell recuperation, is also worthy of a moment's notice. The brain cell, or neuron, receives its restorative elements from two sources—from the intra-cellular nutritive material, stored up during sleep and available during waking hours, and from the lymphatic food material circulating in the lymph, and capable of use only at a certain fixed and comparatively slow rate. When this stored up nutriment is consumed a psychic sensation of fatigue ensues; the individual rests and the store is replenished. In diseased states, or during the circulation of alcohol in the blood, for instance, the cells cannot rest, but are spurred on to a degree of activity which, in its inevitable consumption of substance, results in excessive fatigue, exaggerated in the same degree that the stimulation was excessive. This is morbid fatigue, such as impairs the capacity of the cell to recuperate by the assimilation of nutriment when opportunity does present, a state very similar to that seen in the neurasthenic, and a condition that is present in many cases of hysteria. The cell structures in the hysterical are readily exhausted. They can not withstand any extraordinary demand on them. Nerve cells must be considered to have an individual variation as well as any other organs in the body. Neurons have a three-fold character, as nutritive and doubly connected elements. They must be capable of recuperation and the conversion of nutrition into stored up energy; they must be able to receive impressions and capable of the regulated discharge of this stored-up energy. The activity of these neurons consists in an excitation, rise of tension within the cell, and discharge with reduction of tension, and this is the nervous basis of what, psychically, we call a sensation. Now, this excitation may be faint or vivid in intensity, and the neuron upon which it is projected may respond readily or slowly. In the hysterical state there is a quick excitation and an explosive discharge. The mechanism, while unduly sensitive, readily excited by impressions reaching the cell from without, cannot store up the energy so imparted to it, but it is released readily and without due rearrangement.

This variation in the reception of sensations and the discharge of energy consequent upon it, is similar to the pathological change in the incipient form of disease of these structures, where it has been shown that swelling and softening of the fine connecting fibres between nerve cells—the very first changes that can be detected in the alcoholic, for instance—is correlative with diminished sensitiveness to impressions and the slowness of reaction time in such subjects. In the one instance we have a form of cell structure that does not admit of high or fixed tension, but releases energy fitfully and without order; in the other there is a slowness in the rise of tension in the cell because the store of nutrition upon which it should call is not within its reach, or the line of its functional stimulation interrupted. Combine these two conditions and you have, to my mind, the pathological basis of the hysterical state. There is in it a cell structure such as we have described, and there is often superadded an excessive fatigue that comes from the failure to adjust the excitation of the nervous elements to their supply of nutritive material.

The treatment of hysterical manifestations of the brain requires nothing peculiar. The indications are rest—as complete rest as is possible of the exhausted nervous elements,—and the supply of proper nutritive material. This involves proper adjustment of the environment, the removal of all sources of undue strain or any exaggerated demand on the system, the diversion of cell activity to other portions of the nervous mechanism, the removal of all undue excitement, reflex or otherwise, and the use of every restorative agency within our control.

Locomotor Ataxia.

Dr. Sydney Kuh concludes (*Chicago Med. Rec.*) that the brain is diseased in the majority of, and probably in all cases of locomotor ataxia, that quite a number of the most constant symptoms of this disease are very probably and some of them surely not of spinal but of cerebral origin, and that locomotor ataxia is certainly not merely a spinal but rather a disease of the entire central and peripheral nervous system.

IS CANCER OF THE STOMACH AND ABDOMINAL ORGANS THE MEDIATE CONSEQUENCE OF A CONTUSION?*

DR. LITTAUER.

September 1, 1887, a beer wagon collided with a horse-car, swinging the brake against the chest of the driver, L., who was thrown from the platform. He complained of pain in the chest and formication in the feet and right hand. He was taken to a hospital, ice-bags were applied, and September 7 he was discharged improved. He was at this time 29 years old, and had been in good health for some time, though, taking advantage of the presence of a physician to prescribe for his child a few weeks previously, he had asked advice with regard to some digestive disturbances which the physician considered gastric catarrh.

November 30 the railroad physician certified that he had suffered a contusion of the chest and, in consequence, a shock of the general nervous system.

August 2, 1888, the same physician testified that the gait and speech were uncertain and the latter slow; that the patient was dull and the countenance imbecile; that he was incapacitated for work, and had chronic gastric catarrh, the lungs having suffered from the contusion. From August 14 to September 10, L. was treated in a hospital with thermal baths. The diagnosis was confirmed, with the additional note of apical catarrh of the lungs. On December 1 the railroad physician certified that the condition was on the whole unchanged, and advised treatment at the Charity, to which the patient was admitted January 7, 1889, and where he remained till March 9, 1890.

At least three physicians examined him at this hospital and agreed in this diagnosis already made. Digestive disturbances were noted, though not in detail. During two months of the fall of 1889 the patient had treatment at the Medico-mechanical Institute of Berlin but without improvement, as attested by the physician in attendance.

December 3, 1889, there were noted poor sleep, hebetude, vomiting of mucous when lying on the back, and a disposition to cry. After January 16, 1890, treatment was directed especially toward the digestive symptoms.

After leaving the hospital, L. was sent to the country, but did not improve, and on July 31 the physician at the Charity certified that he did not consider further sojourn in the country, or other therapeutic measures as likely to cause improvement. In October, 1890, he recommenced treatment directed toward the gastric disturbance.

December 20, 1891, Dr. L., the physician at the Charity certified, that the condition was, on the whole, the same, the patient being anæmic, badly nourished, with tenderness in the gastric area and with renewed pulmonary catarrh. He thought that, while the prospect for genuine improvement was slight, it was possible that the patient might become able to do light work after prolonged dietetic treatment with occasional lavage. On his advice, L. was admitted to the Augusta Hospital January 18, 1892, where he remained till March 22. On his discharge it was stated that he had a chronic gastric disorder and was improved. Professor Ewald, however, on April 18, 1892, certified that improvement had not occurred. In contradiction Dr. L. again certified, May 4, 1892, that a marked improvement had occurred, the color of the face being healthy, the tongue clear, the physical powers increased while the pulmonary catarrh had subsided. In opposition to the physical evidence, L. complained of severe pains in the stomach, of disturbed digestion and great weakness. Dr. L. thought that the patient was simulating or exaggerating his symptoms, and considered him fit for light work, indoors or out. Another physician, on August 6, 1892, certified that L. was completely broken down, his nutrition was miserable, his complexion grey, he also noted hebetude, hyperæsthesia of the skin and phy-

*Translated from the Quarterly of Forensic Medicine and Public Sanitation for April, 1895, by A. L. Benedict, A. M., M. D., Lecturer on Digestive Diseases, Buffalo Dental College.

sical depression. September 9, 1891, L. was again received into the Augusta Hospital where he remained until September 20. The assistant physician noted severe pains in the gastric area and loins, as well as marked sleeplessness.

November 11, 1892, the physician who had given the certificate August 6, noted that emaciation had been progressing for some time, that a malignant neoplasm had developed in the intestine of plainly carcinomatous nature, and that the patient could live but a short time. On November 28, he certified that the cancer had no causal relation with the accident of September 1, 1886. The patient died the next day.

Autopsy.—Atrophy of the fatty tissues of the heart, brownish-red muscular tissue, whitish opacity of the endocardium of the left ventricle, upper lobe of right lung distended with air, emphysematous at margin, four liters of serous fluid in the pelvis, numerous large cancerous nodes on the peritoneum, right kidney adherent with surrounding structures through chronic inflammation of cancerous nature, kidney of normal size, pyramids partly atrophied, so that their place was taken by "gulfs" (hydronephrosis); all the remaining abdominal organs more or less firmly united by cancerous growths; diaphragm riddled with cancer and forming a membrane one c.m. thick adherent to the entire upper surface of the liver; cavity of the stomach much diminished in size; complete cancerous degeneration of pyloric area and vicinity of the great curvature; cancerous growths of the peritoneum covering its surface and uniting it to the whole posterior surface of the stomach; pancreas infiltrated with cancer, numerous cancerous nodes of different sizes on the intestine; mesentery and great omentum, lowest part of rectum, to a length of 10 c.m. thickened with cancer so as to form a firm tumor.

Lengthy opinions follow from the physician in attendance and from a Prof. F., reviewing the history in detail and attempting to show that the accident had no causal connection with death, either immediately or mediately. The examination was undertaken at the request of the Imperial Insurance Officer.

The opinion of the writer differs from that of Prof. F. in assigning an indirect causal relation to the original accident. Cancer is at first a local disease as is admitted by both those who consider it a dyscrasia and by those who consider it a germ disease. In the light of modern discoveries, even though we do not know the exact cause of cancer, it seems that a relation can be established between injury and malignant disease. According to Langerhan's Compend of Pathological Anatomy, 1891, a chronic inflammation of an organ or part of an organ, has an ætiological significance in determining the development of cancer. It has been repeatedly observed that from a scar the result of injury, or from an old ulcer of the lower extremities, or a chronic gastric ulcer, cancer has developed. Cancer of the lip predominates among men who smoke pipes, the so-called chimney sweepers' and parafine workers' cancer arises in the same way from definite, repeated, mechanical injuries, and in the digestive tract, the localities of smallest calibre and the transitions of mucous membrane are by preference attacked by cancer. In the latter locations, (Rindfleisch) the brunt of mechanical impact is physiologically borne.

Waldeyer expresses himself as follows: "I have always noticed in my examinations that, in the most recent zone of a cancer, there is almost as rich vascularization of the tissue, with aggregation of colorless blood vessels as occurs in inflamed tissue. Can it not be that the increased nutrition of the tissue and the resulting sponginess of the connective tissue substratum prepare the way for the growth and extension of the cancer? Can not, in the same way, chronic inflammatory processes of local nature, for example, repeated inflammations, finally pass over into carcinomatous degenerations?"

The late professor of surgery in Heidelberg, Professor Weber, said: "All things considered, the heterologous neoplasms probably often arise as plainly local diseases from repeated inflammations of not very high degree, without our being able to make a positive diagnosis."

The utterances of Billroth are also instructive. His pupil, Alexander von Winiwarter, quotes him thus: "In most cases the exact cause for the development of carcinoma are not known, but a whole series of observations exists confirming the appearance of cancer following local irritation, the new growth developing in soil already altered by a pathological process.

I myself have noticed a local inflammation at the point of development of carcinoma in twenty per cent. of all cases. I may note as examples of the development of cancer from irritated localities cases in which carcinoma has occurred on the site of an ulcer that has matterated for years, in a sinus, a fistula, in chronic inflammatory foci. . . . Single or repeated traumatic irritations can, under certain circumstances, afford an impetus to the development of cancer."

Professor Gusserow, without reference to theoretical considerations, speaks as follows: "Various local diseases of the cervix uteri appear to be of the greatest significance as predisposing causes to the development of cancer. In this category belongs long continued catarrh of the cervical mucous membrane, with the formation of erosions."

Professor von Ziemssen, referring to the occurence of cancer of the larynx, says: "The cause is quite obscure. In only one case out of ninety-six traumatism—fracture of the thyroid cartilage through an attempt at strangulation—had preceded neoplasm by a few months."

Stoerck of Vienna contributes a case of cancer of the epiglottis in a man fifty-two years old, in which the patient attributed the trouble to swallowing a fish bone. The bone had remained for a long time before it could be grasped.

Of the symptoms of laryngeal cancer, hoarseness is by far the most constant, the earliest and the most permanent. According to von Ziemssen, hoarseness preceded other symptoms by many years, for example, three, four, five, and, in one case, twenty-six years. A prodromal stage of one or two years seems to be the rule. Do not these facts signify that chronic catarrh of the larynx precedes cancer and conduces to its development?

Professor Luecke says: "I believe by all means that we have every reason to inquire for the local inflammations that engender tumors. They possess real ætiological moment with respect to the development of tumors, yet they cannot be of immediate diagnostic value because certain inflammations do not always call forth certain tumors. Repeated as well as single irritations by pressure, friction, or the flow of secretions are given as the causes for the most various benign and malignant tumors.

After weighing carefully the testimony of Professor F., and again referring at length to the history of the patient L., the writer reached the following conclusions:

(1) By the accident, on account of the contusion of the chest and gastric area by the brake, processes were originated through which, in course of time, cancer could develop in the stomach and neighboring internal organs.

(2) In the documents no account is taken of processes or anatomical changes from which one can decide upon an idiopathic origin of cancer in L.'s case.

(3) By the continuity of the processes from the moment of the blow of the brake on the anterior chest wall and gastric area to the death of L., it is highly probable, from a medical standpoint, that a mediate causal connection obtained between the accident on September 1, 1887, and the death of the patient. The degree of probability cannot be stated mathematically, but, to myself, this probability amounts to a certainty.

Obstruction of the Bowel Tested by Electricity.

Althaus (*British Medical Journal*,) reports a case of a man fifty-four years old, who for three months had suffered with obstinate constipation. At the time of coming under observation the bowels had not been moved for ten days, and the abdomen was distended and tender. The appetite was lost, and a condition of collapse existed, with sunken face and small, feeble pulse. The introduction of the long tube proved unavailing, and electric treatment was resorted to. An insulated sound with a fine metallic end, was introduced nto the rectum, and a moistened conductor applied to the abdominal parietes, chiefly in the region of the sigmoid flexure. Through this circuit a primary faradic current was passed, and its force gradually increased until the patient experienced a decided feeling of vibration in the bowel. In the course of the day a copious intestinal evacuation ensued, with wonderful relief to all the symptoms. During the next two days the bowels acted ten times, and in the course of a week the patient appeared quite well.

A second case, in a woman fifty-seven years old, is cited, in which a like result was obtained from similar treatment. (*The Medical News.*)

MALARIAL HEMATURIA.

CHAS. E. CATCHINGS, M.D., WOODVILLE, MISS.

To my mind there is no disease on earth so much dreaded by the inhabitants of malarial districts as this "Monster Hematuria." It may be defined as a miasmatic acute infectious fever; characterized by an initial chill, with manifestations of an inflammation of the whole kidney structure, especially in the mucous membrane, which is as pathognomonic as is the membranous deposit upon the tonsils and fauces in diphtheria. It attacks the white man, especially the laboring class, more often than the negro, who is capable of taking it on and throwing it off without any deleterious effects. It prevails throughout the whole southern climate, especially in localities abounding in lakes, stagnant water courses, swamps, etc., which are conducive to vegetable decomposition and miasmatic fevers. There are probably as many forms of this type of malaria as there are pernicious forms of malarial attacks.

History.—Malarial disease, accompanied with vomiting of black bile, with petechia and with hemorrhages have, from time immemorial, been frequent and fatal in the warm, marshy countries bordering on the Mediterranean and Black Seas. They appeared with such dangerous and putrid symptoms as not only to have been called pestilential, but to be confounded with the plague itself. Rome was often afflicted with malignant malarial fever. This seemed to be due to the marshes and stagnant pools around the city for, when drains and common sewers were laid and the Pontine marshes drained, Rome became a healthy city. In Alexandria there seemed to be a similar disease that was very much dreaded in the Autumn after the recession of the Nile. Prasper Alpinus says, "It began by nausea, sick stomach, vomiting of bile and passage of bloody urine with jaundice. Dr. Livingston speaks of this dreaded disease in his ', Travels in Africa ;" and all know of its fatality in the West Indies, Central and South America.

One of the most remarkable circumstances connected with hematuria is that it occurs as an endemic disease in some countries. In the Isle of France three-fourths of the children are affected with hematuria at some time or other. Among the predisposing causes are bad hygiene and sanitary condition, improper diet, etc. The chief cause is said to be due to the parasite hematuria discovered by Bilhorz. It is an elongated, soft-skinned, bi-sexual entozoon, three or four lines in length, of the trematode or fluke kind. It inhabits the branches of the portal system and the minute veins of the pelvis, of the kidneys, uterus. and bladder. When a patient lives in a marshy country there is generally an overplus of malarial poisoning in the system, a chronic malaria in the form of "chronic chills.' The system has been affected with these malarial germs, the plasmodia of Laveran, and your patient has been using every patent "chill tonic" that he could find in the drug store, and God knows what else, only adding insult to injury.

With reference to the pathological anatomy the profession is not united. Our text books give very little on hematuria. This is plain enough because all our standard authors live in the North where they never see a case; hence we have to get it from our own observations. We find that the color of the skin varies from a light to a dark yellow according to the case, and is of a perfect uniform tint. Everywhere the stomach is perfectly sound when the patient has not formed any drunken habits. The gastric juice is green, limpid, or contains lumps of green matter exactly like chopped spinach. We find the red blood corpuscles in the urine, but some deny their presence and say that we find only the hematin, and that we have hæmoglobinuria or urine containing blood-coloring matter. I have examined the urine under a magnifying power of 430 diameters. The urine was found to contain numerous casts of tubuli uriniferi. The casts were filled with crystals and fragments of granules of the coloring matter of the blood. I also found a few altered blood corpuscles, but if they had ever been present in large

numbers they had been destroyed by a mixture of the bile and urine. There is no doubt but what we have extreme hematuria in the kidney structure. The capillaries become so engorged with this poisoned blood containing the germs, plasmodia of Laveran, that they may rupture. Oxidation is interfered with and, of course, will cause degeneration.

After death you find the exterior of a golden color, the *liver* enlarged and of a slate color on the surface and a deep bronze color within. *Gall-bladder* is distended with greenish. almost black bile. *Spleen* is enlarged and filled with black pigmentary particles similar to those absorbed in the liver, and it has all the appearances of a malarial spleen. *Stomach* is filled with a fluid similar to that found in the gall-bladder. *Kidneys* are found to have some slate-colored spots on the surface, and they are also greatly congested and of a dark-purplish appearance. The *blood vessels* are filled with coagulated blood. *Bladder* contains a large amount of bloody urine.

The patient first begins to look anæmic and to have chills, but this he does not pay much attention to; probably walks about while he has a chill. Finally he goes out and voids bloody urine, and then sends for a doctor. When you get there you find your patient with a haggard expression about the face; the sclerotics of a yellow or golden color, and the skin nearly the same color. Patient will tell you he has had a hard chill and then passed bloody urine. He then has high fever and is very restless; bowels constipated, and, probably, the kidneys acting very slowly. The liver is engorged and spleen enlarged. Then you have a genuine case of malarial hematuria, and it is the place for you to show your skill as a physician.

I do not think a genuine case can be confounded with anything else, if the physician has ever seen a case before. It comes nearer yellow fever than anything else.

Prognosis is generally guarded, but if seen in time and properly treated the case will recover. Uremia is the thing to be feared, but if you get the liver and kidneys to act well there is not so much dread, though I do not believe that a genuine case of hematuria ever got entirely well, for, usually, nephritis develops after the hematuria.

There comes the "tug of war" where Greek meets Greek, and so it is when physician meets physician in the treatment of this dreaded disease "hematuria." I do not remember, but it has only been a few years ago when quinine was considered the sole remedy; to-day we have learned better. I admit that quinine is destructive to the germ—the plasmodium of Laveran. But study the physiological action of quinine and the pathology of hematuria and you will see that it is not indicated. Look! The patient is already depressed and the kidneys in a crippled condition—they are hyperemic. Bartholow says medium doses of quinine cause hyperemia of the brain and depress the heart's action. It acts on the cardiac motor ganglia, and causes feeble movements of the heart and lowers the vascular system. This is just what we don't want. Dr. Elliott, my professor in Tulane University, would preach all day, "Give quinine," but I have learned better, and the man who does give it is not a conservative practitioner. Again, quinine in long continued use will irritate the stomach, and you know that in hematuria nausea is the worst symptom we have to combat. I have seen it really alarming. Then give quinine? No, some will say, give it hypodermically. If you do sometimes produce abscesses. I do not believe quinine is perfectly absorbed when given internally, therefore it must be an irritant. This hemorrhage is what you are trying to stop. If this is so, then you do not want to use quinine, for I do not remember ever seeing where quinine was used as an hemostatic. We all know that hemorrhage is only a symptom in hematuria, and there is not a case on record where quinine arrested hemorrhage. As this is so, we must resort to some other remedy. And now, if you will follow me, I will give you a treatment which I believe every physician from the Delta will endorse, a treatment that I consider the most conservative one—one in which the powers of the patient are supported and this dreaded poison eliminated. And to do this we give something to arouse the secreting and excreting organs—the liver and kidneys—and for this what are we going to give? Is it quinine? No! Is it hyposulphate of sodium? No! Still I was taught by two of the brightest lights of our profession—Dr. Elliott of New Orleans and the illustrious Dr. Sim of Memphis—to give

it. Do I give it? Yes; sometimes; and I have seen what I thought pretty good results from it. But there is one other remedy which I must speak of, a remedy time-honored for a great many diseases, one which we have all had to use. I speak of the "Great Mogul"—calomel. It may be given *ad libitum*, say ten to fifteen grains every hour, until you get the physiological effect. I have seen as high as 100 grains given in five hours. I usually give it in eight or ten grain doses until I get the desired effect, and then follow it with hyposulphate of sodium or this prescription:

	Sulph. Magnesia	℥ ss
	Aromatic sulph. acid, gtts	10
	Tr. opii, gtts	5
Sig.	Take at one dose.	

This I give about every three hours for the nausea, and give either cracked ice or water as hot as the patient can drink it, and the patient will soon learn to like it.

As soon as my patient shows signs of improvement I give some diuretic, preferably acetate of potash and the following prescription:

	Phosphoric acid (dil.)	♏ v
	Strychnia nitrate, gr	i
	Aqua, q. s.	℥ iv
Sig.	Teaspoonful every four hours.	

The acid has a tendency to arouse the liver to action, and the strychnine acts as a stimulant.

But, in conclusion, let me say, whatever else you do, support your patient and use the eliminative treatment.

WOMEN IN THE MEDICAL PROFESSION.*

LOUISA C. DROUILLARD, M.D., MEMPHIS, TENNESSEE.

From the earliest time since women have taken up the study of medicine, the department of mid-wifery was almost entirely given over to them, but it was not until 1848 that woman entered the field with a school of her own, and entered to remain. In Europe the admission of women to the profession had been widely opposed because of disbelief in their intellectual capacity, in America one is less often permitted to doubt aloud her intellectual capacity; the controversy was therefore shifted to the ground of decorum. While women were allowed to practice mid-wifery it was because it was assumed that that department of medicine did not require the assistance of medical art; that women in labor traversed a purely physiological course and only required the attendance of kindness, patience and natural sagacity, all obtained without scientific knowledge from her own sex; but when the necessity for knowledge was recognized, when men became skilled while mid-wives remained ignorant, the choice was no longer possible and the great welcome of mid-wifery was obliged to yield to the greater safety of enlightened masculine practice. The history of medical women in the United States may be divided into seven periods.

1st. The Colonial period. During this period of female mid-wifery the medical profession proper of the colonies remained entirely unorganized. Without making inquiry a superficial observer could have almost overlooked the existence of doctors as a special class in the community.

The second period was that of the Revolution. At this time physicians began to travel to Europe for instruction, and during the war their services in the military hospitals, though apparently not very useful to the sick, served to bring the profession for the first time out of obscurity and resulted in the collective observation of disease on a large scale. More than one hundred and fifty years elapsed after the first settlement before a single effort was made, either by public authority or by the enterprise of individuals, for the education of physicians, or for improving the practice of medicine; no medical journal was published until the close of the eighteenth century, and the first anatomical dissection was made in New York,

* Read before the Tennessee State Medical Society, April, 1895.

in 1750. The first achievement of the new-born art and education was the expulsion of "females" from every out-lying province of the profession, and from the world-old traditional privilege as accoucheee. It was a harsh return to make for the services rendered to the infant settlement by those valiant mid-wives who tramped through the snow by night and by day to bring into a very cold world the citizens of the future Republic.

After this came a period of reaction. In 1848 a Boston gentleman, Mr. Samuel Gregory, began to protest against the innovation of male mid-wives and, to judge by the contents of the public press, opened a crusade on behalf of the women. Mr. Gregory's protests awoke sympathetic echoes, and some that were not sympathetic, for the President of the British Medical Association said: "I am not over squeamish, nor am I over sensitive, but I almost shudder when I hear of things that ladies now do or are attempting to do. One can but blush and feel that modesty, once inherent in the fairest of God's creation, is fast fading away. You, gentlemen, who know the delicacy of woman's organization, must know that constitutionally they are unfit for many of the duties of either doctor or nurse. May not habit so change that fine organism that sensitive nature of women, as to render her dead to those higher feelings of love and sympathy which now make our homes so happy, so blessed?"

The fourth period was initiated when Mr. Gregory, supported by the popular enthusiasm which he had aroused, succeeded in opening a school of medicine (so called) for women, in November, 1848. The first term lasted three months; a second term began the following April, 1849, with the announcement that the twenty pioneer pupils had not only followed the lectures but had attended about three hundred mid-wifery cases with the most satisfactory success. In the prospectus issued for the second year of the school, Mr. Gregory brought forth a new set of reasons for its support; that in New England there was a surplus female population of 20,000, and hundreds of these would be willing to devote any necessary length of time in fitting themselves for a useful, honorable and remunerative occupation. They could afford, moreover, to give their services at a much cheaper rate than men, charging about one-third the ordinary fee—thus, five dollars instead of fifteen for attendance on a confinement case. Thus not only would the morals of the community be preserved, but the burden on its purse be considerably lightened by the employment of educated women as obstetricians. As the medical profession has become keenly alive to the lucrative character of obstetrical and gynæcological practice, this suggestion that it might now profitably be undersold, naturally aroused the keenest resentment. It was soon reported that the cheaper practitioners were to be prepared by a system of education so cheap as to be absolutely worthless and, unfortunately, the early history of the first medical schools for women entirely justified this accusation. In 1850 the Woman's College of Pennsylvania was founded, and after a long and precarious period it finally rested upon a solid basis.

Period five; the struggle for an entrance into the reputable colleges. Half-a-dozen women, unknown to each other and widely separated, appeared almost simultaneously upon the scene and demanded opportunity to be educated as physicians. The first of this remarkable group of women was Harriet K. Hunt, of Boston. This lady had for several years assumed the responsibility of practicing medicine while yet unprovided with a medical diploma. This was reprehensible, but from a practical stand-point the course seems to have been justified by subsequent events for when in 1847 Miss Hunt requested permission to attend lectures at the Harvard Medical School, her request was promptly refused. After the graduation of Elizabeth Blackwell at Geneva, in 1839, Miss Hunt thought that the times might have become more favorable and in 1850 repeated her application to Harvard. On this occasion five out of the seven members of the faculty voted that Miss Hunt be admitted to the lectures on the usual terms provided that her admission be not deemed inconsistent with the statutes, but when the students heard that a woman was to be admitted they held an indignation meeting and the faculty advised the female student to withdraw, which she did, but she continued her practice, and in 1872 celebrated her silver wedding in the profession.

Elizabeth and Emily Blackwell were led to the study of medicine in a different manner than Harriet Hunt. While still quite young their father died leaving a large family to their support. They wrote:—"When we realized the infinite narrowness and pettiness of the avenues open to women, we determined to open a new door and tread a fresh path." In this determination a new keynote for women was founded. It was in 1845 that the plan of studying medicine became a settled resolution with Elizabeth Blackwell, and she was thus the first woman on the American continent to whom such an idea had come. She applied for admission into twelve medical colleges throughout the country and at last was admitted at Geneva, N. Y. The faculty referred the matter to the students and they decided to invite the courageous applicant. After graduation at Geneva in 1849, the first woman in America of modern times to receive a medical diploma, Miss Blackwell went to Europe and by exceptional favor succeeded in visiting some of the hospitals of both London and Paris. Emily Blackwell was refused admission to Hobart College at Geneva, but was allowed one year's study at Rush College, Chicago. For this permission, however, the college was censured by the State Medical Society, and the second term was denied her. The College at Cleveland, Ohio, permitted her to complete her course, 1852. After this she became a pupil of the celebrated Sir James Y. Simpson of Edinburgh, who gave her the highest praise, as did several distinguished physicians in London and Paris in whose hospital wards she worked. In 1855, the two sisters opened a little dispensary for women which grew into the New York Infirmary. In 1850 Dr. Marion Sims arrived as an exiled invalid from Alabama. With a brilliant, original surgical operation as his stock in trade, he succeeded, with the aid of some generous New York women, in founding the first Woman's Hospital in the world. Now that there was a college in Philadelphia and a hospital in New York, more women entered the profession, but their trials and difficulties to a less determined set of women would have been unsurmountable. These did, indeed, walk by faith and under an overruling Providence.

The sixth period was the founding of hospitals where women could obtain clinical training. The New York Infirmary in 1854 by the Drs. Blackwell; the Woman's Hospital in Philadelphia in 1862; the Hospital for Women and Children in Chicago, by Dr. Mary Thompson, that pioneer of women in the West; in San Francisco, Cal., in 1875; in 1882 in Minneapolis. In 1865 a school for women was opened in New York City, much against the will of the leading women physicians, as they were anxious for the admission of women into the good colleges, but the colleges would not admit them, not but that the women had loyal friends among the men, but these were in the minority. In 1869, under the patronage of that grand man, Dr. William Byford assisted by other progressive men and by Dr. Mary Thompson, a college was founded in Chicago that has grown from beginnings so small that at one time lectures were given in a building that had been the stable of the Women's and Children's Hospital, and as Dr. Byford, in reviewing the history at the dedication of a handsome new building with every facility, said, "It did have a very horsey odor." This college has borne Dr. Sarah Hacket Stevenson, Dr. Eliza Root, Dr. Marie Kreigler, and many others that are honors to the profession. In Michigan the State University opened its medical department to both sexes. Since this, colleges for women, especially in the West, have received hearty support.

Then came the struggle for official recognition in the profession. In the prolonged debate which followed, woman's cause was defended by many distinguished men with as much warmth as it was opposed by others. The Philadelphia County Medical Society assumed the responsibility of being the first to check the alarming innovation of woman's schools and female doctors. In 1859 was introduced the resolution declaring that any member who would consult with women should forfeit his membership. Upon this resolution the censors declined to express an opinion; endorsement was, however, obtained from a committee of the State Medical Society. The recommendations of this Society were supposed to be manditory on all the County Societies throughout the State, but the Montgomery County Society, under the chivalrous inspiration of Dr. Hiram Corson, passed a resolution that "females, if properly educated, should receive the same

treatment as males, and that it was not just to deny women admission to male colleges," and after they had, with great perseverance, established one for themselves, to refuse it recognition. In 1870 this Society elected Dr. Anna Lukon to membership. In 1871, when the American Medical Society met in San Francisco, and the female physician question was subjected to a long and eminated debate, Dr. Atlee of Philadelphia, remarked that the opposition to female colleges generally came from the professors or contributors of other colleges. "These woman's colleges now stand in many respects better than many colleges represented in the Association, and give obstetrical and clinical training such as is not given in a majority of the colleges for men. By the rules of our Medical Association I dare not consult with the most highly educated woman physician, and yet I may consult with the most ignorant, masculine ass in the medical profession." In 1881 the first woman delegate was admitted as a member of the State Society of Pennsylvania, and in 1876, Dr. Sarah Hacket Stevenson was sent as a delegate by the State Medical Society of Illinois. Dr. Marion Sims was President that year of the American Medical Association, which met in Philadelphia. By an almost unanimous vote the mighty question which had disturbed the calm of so many medical meetings was settled through the influence of Dr. Jacobi of New York. Dr. Mary Putman who was the first woman of America to graduate from the Paris E'cole de' Medicine, received professional recognition. In Philadelphia, women were championed by Drs. Hartshorne, Atlee and Thomas; in Boston, by Drs. Bowditch and Cabot; in Chicago, by Dr. William Byford. The various State Societies have admitted women the years following: Kansas, 1872; Iowa, 1874; Vermont, 1875; Maine, New York and Ohio, 1876; California and Indiana, 1873; New Hampshire, 1879; Minnesotta and Massachusetts, 1880. In 1886, 91 hospitals in the United States admitted women to their clinics. In Philadelphia, in 1883, the first woman interne was appointed to the Blockley Hospital after a competitive examination. In 1881, two women were placed on the visiting staff. In Chicago, the hospital privileges have been most equitably distributed. Cook County has had five women internes, and the Insane Asylum has a resident woman physician. Dr. Sarah Hacket Stevenson is a visiting physician to the Cook County Hospital. Dr. Carson of Pennsylvania, at the meeting of the State Society offered a resolution, "That a female physician be appointed for each insane hospital or asylum where female patients are confined." This has been done in many states, both for the good of the institutions and the profession, and it is to be hoped that it will soon be so in every state. In 1882, Dr. Putman Jacobi was invited to lecture on Children's diseases in the New York Post-Graduate College, she being the first woman to lecture in a masculine school. Dr. Sarah McNutt holds a chair in the same school. If time permitted, a history of the work that women have done and are doing would amply repay the earnest effort of those who have been the means of elevating woman to the place she now so ably fills in every department of the profession.

As yet women have not accomplished much from a scientific standpoint; they have been doing pioneer work. But they have a resolute helpfulness in dealing with the individual cases entrusted to their care, and a passionate loyalty to those who who have put their trust in them. Today, the woman physician has every opportunity to fit herself to combat disease and she has the help and sympathy of the profession. Now it is hers to show by conscientious, faithful work that woman will be in the profession an honor and a refining influence.

Four years ago I came among you a stranger, and from the first I have received only kindness and consideration, I being the first woman on whom you have conferred the honor of reading a paper before you. I thank you.

A Serviceable Rule.

Dr. Goodell never passes a sound into the uterus without first demanding a full history of menstruations.

Attention to this rule will often prevent your tendering the designing patient a cheap abortion. Even with a clear history he repeats the rule of the elder Dr. Goodell, "cervix hard as the tip of your nose—no pregnancy exists. Cervix soft as your lips —pregnancy almost certain to exist."—*Medical World.*

THE MEDICAL AND SURGICAL REPORTER

ISSUED EVERY SATURDAY

Address all communications to 109 and 111 Fifth Avenue, New York.

HAROLD H. KYNETT, A.M., M.D.
Editor.

RODERIC C. PENFIELD
Publisher.

Editorial Offices, 109 and 111 Fifth Avenue, New York.

Entered as second-class matter at Asbury Park, N. J.

TERMS:—Three Dollars a year in advance. Sent four months on trial for $1.00.

REMITTANCES should be made payable to the Publisher only, and should be made by Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We invite contributions of value to the profession, and if published originally in THE REPORTER such will be paid for at liberal rates, or a limited number of copies of THE REPORTER will be supplied, as the author may elect. Hereafter where reprints are desired writers are requested to make a note of that fact on the first page of the MS., but must order reprints directly from the publisher, who will supply the same at cost rates. Contributors should inclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, JUNE 22, 1895.

EDITORIAL.

THE REMOVAL OF THE "REPORTER."

The publishers announce the removal of the MEDICAL AND SURGICAL REPORTER from the present address in Philadelphia, Pa., to New York City, where it will occupy quarters in the magnificent new Constable Building, 109–111 Fifth avenue, corner of Eighteenth street. Both the editorial and the business offices will henceforward be located at this address. All persons whatsoever having business of any kind with the MEDICAL AND SURGICAL REPORTER, will please make note of this change and direct all communications accordingly. Exchanges are requested to make immediate alterations in their mail lists. Books for review, reprints, original articles, and all communications of any nature intended for editorial attention, should be directed specifically to the Editor of the MEDICAL AND SURGICAL REPORTER. All matters relating to the business conduct of the journal should be directed specifically to the publishers. Considerable time will be saved and many mistakes avoided if correspondents will observe this simple request.

This transfer to New York City has long been contemplated and, after careful consideration of all questions involved, the publishers' decision is as here announced, they having become convinced that the highest interests of the REPORTER and of its vast patronage will be advanced by the change.

Forty-three years ago, when the MEDICAL AND SURGICAL REPORTER made its first appearance in Philadelphia, American medical journalism was in its incipiency and Philadelphia long had been and still was, the undisputed centre of American medicine. The development and changes made during these forty odd years, have been as great and as radical in the science of medicine and its correlative enterprises, as have been the changes and developments in any field of human effort. The REPORTER has grown with the growth of American medical science. It has kept its

position in the front rank of medical journalism, and it is because of its determination to advance yet further and higher that the present change is made.

It may seem somewhat venturesome for a journal to remove from the place where it was born and has lived for so many years, and undertake to establish itself in a locality where the field is already occupied by journals of the highest character, but the REPORTER is not going to New York to seek a living as an artisan out of employment. It goes as a well established business seeking opportunities for enlargement and growth under conditions which will allow of such. In journalism, as in almost any other business, of all cities in the East, New York unquestionably offers the finest facilities. Instead of going to New York to "hunt for work," the REPORTER takes to that city all of the interests and influences acquired during a successful career of more than forty years.

Again, while Philadelphia has been the abiding place of the REPORTER, this journal has never professed to be distinctively representative of the local profession. Indeed, surprising as it may seem, with so great a number of medical journals published in that city, Philadelphia has not one periodical which can be said to represent the local profession. Several publications issued are avowedly in the interest of one or another individual institution. No journal, however, represents Philadelphia medicine in the same sense that the local professional interests of other large cities, as New York, Chicago, Boston, etc., are constantly represented by the journals published in these respective cities. This is a great misfortune to local interests as eventually, must be discovered by those who are responsible, who live apparently only to preserve ancient customs, and who evidently are blind to the fact that the "world do move." The greater misfortune, however, is to the cause of scientific medicine and the advancement of higher medical education, for no body of scientific men, at home or abroad, is, so far as professional qualifications are concerned, superior to the medical profession of Philadelphia. For such a body wittingly to allow the continuance of customs and policies which we little influence and suppress knowledge which of right should be given to the entire profession is, now, as culpable as, presently it will be found to have been suicidal.

It has been the design of the REPORTER to present to the profession-at-large medicine in general rather than local interests, and since it is not essentially dependent on local support, residence is a matter largely of convenience and business facilities. The removal of the entire business to New York will involve no change in the REPORTER'S policy, but it will open up some opportunities for increasing its usefulness and enhancing its value to the general practitioner, for whose use in practical application, it endeavors to supply accurate information of the procedures of modern medical science.

Diphtheric Vulvitis in a Child.

Gnichtel (*Jour. of Cutaneous and Genito-Urinary Diseases*) has reported the case of a girl, one year old, who for five days had been irritable and restless and appeared to suffer pain referred to the gential region the symptoms being aggravated during micturition. Examination disclosed several patches of false membrane covering anteriorly the internal portion of both labia majora and nymphæ and invading the urethral orifice. The membrane was firmly attached and grayish-white in color. It was further learned that two fatal cases of diphtheria had recently occurred in the house in which the child resided, the last but a week before she was taken ill. There were no other symytoms. Bacteriologic examination of the membrane revealed the presence of diphtheria-bacilli. The patches disappeared upon the use of local applications, chiefly of hydrogen dioxid and mercuric-chlorid, and the child made a good recovery. At no time were marked constitutional symptoms observed.

SOCIETY REPORTS.

THE MANAGEMENT OF THE NEW-BORN.

See page 847.

DISCUSSION.

DR. J. W. BRANDEAU, Stribling: I have a few remarks to make. The first is as to the length one cuts the cord. I was taught and have been in the habit of cutting the cord about two inches in length, giving room for the application of a second ligature before putting on the dressing, which I apply midway between the first one and the abdomen of the child. I have never had a case of hemorrhage from the umbilical cord.

As to the dressing of the cord. I have been in the habit of using just plain clean cotton cloth—cheesecloth when I can get it in the house perfectly clean. I cut a little hole in the center, bring the stump of the cord through, and lay it to the side it will go the most naturally. I then take another clean fold of cotton cloth and place it smoothly over the cord, and over this place the flannel band. I do not advise the use of grease because that retards the absorption of the cord.

As to asphyxia. I think the old-fashioned way of blowing into the nostrils of the child gives the best results. I have been told that by this method we blow carbonic acid gas into the child, but I believe that with two or three deep breaths we so change the residual air that we do not blow much carbonic acid gas into the child. I have worked on them sometimes an hour, even after the heart would cease, sometimes before natural respiration would supervene.

As to feeding the child. When the child rests quietly it should not be disturbed. When it becomes hungry it will let you know. I put it to the breast that it may get the first oily substance in the breast, which acts as a laxative; and to promote the action of the uterus in this way reflexly I use the cow's milk, adding a little sugar to make it more palatable.

DR. T. J. HAPPEL, Trenton: I don't agree with the paper. I don't believe some of the statements there are true. I would never waste two hours fooling away with a dead child. If it is dead it is dead, and we ought to know whether or not it is dead within less than two hours.

Another thing, I never saw a piece of adhesive plaster placed on a surface without producing an eruption of some kind. Consequently I wouldn't place a piece of adhesive plaster on the abdomen of a child. I would use the band also as a preventive, for I would rather take the preventive measures than to try to cure.

As to the feeding. I don't think the Lord ever made a baby but he provided a way to feed it, and I believe the Lord has provided also the best bottle ever made for that purpose; and let us use that to feed our babies and not feed them on Mellin's food nor cow's milk nor anything else.

DR. T. K. POWELL, Dancyville: I think it is altogether unnecessary to tie the cord twice. We can leave the part of the cord towards the placenta loose. I think more children have been starved to death on Mellin's food than have ever been saved; and as to the fat meat, I don't see any advantage it could be, except possibly to make the child swallow better. It has been used by the darkies for this purpose. A piece attached to a string would be suspended from the ceiling in the middle of the room, a little above the children's heads. When the little negroes could no longer comfortably swallow the bread upon which they were fed, they would jump up and catch the piece of fat meat in the mouth, thereby lubricating the parts.

DR. N. C. NEWMAN, Normandy: I don't see the necessity of giving the newborn babies whiskey. As to the fat meat, the baby's stomach and intestinal tract are not in a condition to digest oils and meats. This can only make the baby sick. There is not a man here that can ramapiece of fat

meat down his throat without it making him sick.

As to tying the cord two or three inches long. It is a wholly useless structure after it is cut, and there is no hemorrhage from it even if you don't tie it at all. I don't see the necessity of cutting it two or three inches long.

Dr. H. J. Warmuth, Smyrna: If the child is apparently dead and warm water does not revive it, I introduce my finger into the rectum and attempt to dilate the sphincter ani. If that does not effect anything, I am satisfied the child is dead. I do not apply two ligatures to the cord. It cuts off quicker without them.

Dr. C. Holtzclaw, Chattanooga: The feeding by mothers must be stopped. It is simply a relic of barbarism. In these days of artificial light, syphilis, tuberculosis and dyspepsia, there is hardly one mother out of a hundred gives good rich food for the infant. Artificial milk, cow's milk, is the only food which should be used, and mother's milk should not be given to the child unless it can be properly sterilized. I would like my friend Happel to get a law passed through the Legislature to have nursing by mothers stopped.

Dr. W. Frank Glenn, Nashville: Genito-urinary men sometimes have something to do with new-born babies. There is no other subject, I believe, in the practice of medicine in which there is more folly and the exercise of less common sense. We give up too soon in nearly every instance in the attempt to resuscitate the new-born baby. I don't think we ought ever to cease work under three-quarters of an hour, at least. We are not scientific enough to say when they are dead. They may not breathe and the pulse may not be perceptible, yet they may live. One thing I disagree with Dr. Marable in. If the child cries, give it a little catnip and whisky. If the child is ill during the first few days, he is usually hungry. If the mother's milk does not satisfy him, give him some cow's milk and sterilized water sweetened. Nature is the best guide on earth as to food.

Dr. Happel: Didn't you say yesterday, if the child cried the best thing was to circumcise him?

Dr. Glenn: Immediately on ligating and cutting the cord, I would remove the prepuce; therefore, that would have been done and could not be blamed for it.

As to the cord. You have here a useless appendix, which must slough off. You need simply antiseptic dressing. I wrap it, after cleaning, with carbolic gauze, then with soft cotton to protect the abdomen of the child, and secure it, and in a few days it sloughs off and the umbilicus is well. I do think if anything in medicine needs common sense and the discardance of old women's advice, it is the management of the new-born. It is a mistake to think a person living at a cross-road in the country is not entitled to the scientfic practice of medicine as well as those in New York City and London. If the old women in a cross-road of fifty inhabitants would say: "Put a piece of fat bacon in the child's mouth," I would say, "No, I don't want it." And if they said, "Why, we have all done it," I would say, "The child's mouth was made for the mother's milk and not for the fat." Then, for the cord, plain antiseptic dressing is all that is necessary.

Dr. M. L. Bradley: Saddlersville: We have neglected to speak of the eye. I always use a solution of nitrate of silver, which is dropped into the eye. My brother, over there, would lead us to believe that the mothers are infected with diseases, that the child has to pass through an infected passage, and the child's eyes are exposed often to the gonorrhœal discharge, which could be gotten out of the eyes and the child protected from the disease the mother had.

Dr. Roberts, I want to say a word in defence of the scorched linen. In this regard the old women were ahead of Lister, for they rendered it aseptic. Therefore, if you have to resort to a piece of cotton or linen which has been lying in the drawers for a long time, by passing it through the flame you, to a certain extent, get rid of germs.

You make it more or less absorbent, if it is dry.

Dr. Smith: The method of Crede is the introduction into the eye of a two to nine per cent. solution (ten grains to the ounce) of nitrate of silver. This should be dropped into the eye immediately after birth after cleansing any discharge on the outside of the eye. This has reduced the percentage of ophthalmia neonatorum cases from ten to less than one per cent.

DR. GLENN: Do you mean every child born is to have medicine dropped into its eyes, whether you know of disease or not?

DR. SMITH: Yes, sir.

DR. GLENN: I would never agree to that. It is unnecessary to drop any such solution into the new-born's eye.

DR. SHEDDAN: That may be all right in the state of New York, where nearly the whole state is a city, but in country practice ophthalmia neonatorum is a very uncommon disease, and I think it would be absurd and ridiculous to go through any such procedure.

DR. BAXTER: It is not a question of the country or city, but the chance of ophthalmia neonatorum arising. New York recognizes neither city or country, and it has reduced the rate markedly. It is a scientific point we are arguing.

DR. SHEDDAN: In this work of obstetrics in the country you may take the universal opinion of country men. What is it you wish to prevent the eye against? Irritating vaginal discharges is all you claim for it, from gonorrhœal infection from the mother. In country work, as my friend, Dr. Joseph Price has said in his acquaintance in the valley of Virginia, ophthalmia neonatorum would be as great a curiousity as would be a case of leprosy in the city of Philadelphia, or more so. No, sir; I wish to say with Dr. Price, in this work where due precaution is used—I admit it is needed in the cities—it is absolutely useless to talk of dropping such a solution into *every* child's eyes. I would like to ask if that prescription was in the Garden of Eden, and has it been handed down ever since? When did blindness commence? In my practice in the country, in 554 cases of labor I have never seen ophthalmia neonatorum, except in the negro population.

DR. HITT: Our friend has just spoken of ophthalmia neonatorum in the Garden of Eden. I have just returned from a district as near to it as any man can get—India,—and I will say there are thousands and thousands of children born there annually who have this disease.

DR. OMOHUNDRO: It is a law in Austria to use a two grains to the ounce solution of nitrate of silver. It is considered malpractice if the doctor fails to introduce it.

Dr. W. I. EDWARDS, Nashville: I think a physician should have sufficient intelligence to know when a child he delivers is subject to such trouble, and then is time to apply the nitrate of silver and not put it in every infant's eyes.

DR. H. BERLIN, Chattanooga: The nitrate of silver is recognized as a preventive throughout the whole civilized world. As to my friend saying such a disease does not exist in the country, my experience is quite different. Cases of this kind of disease are not stayed, it seems, by the hand of man. Consequently, he may not know what is going on in his own community. As nitrate of silver in such strength as is recommended, a one or two per cent. solution, can do no harm to the eye, and, it seems, may do considerable good, there is no contraindication for the use of it. In fact, in Austria the mid-wife carries not only the carbolic solution for the hands, but she must also carry this solution of nitrate of silver for the eyes of the child. Now, Dr. Glenn says every boy should be circumcised as soon as born; why not put this in the eyes of the baby at the same time? It is not absolutely necessary to understand that we must use it as a preventive against this disease produced by the gonococcus. It has been remarked that in India it is produced, not by gonorrhœa, but by the filth and dirt. Now, if the gentlemen in the country would come to the city, it would give them a good chance to see how these things are transferred from the cities to the country.

DR. SMITH: In regard to the point Dr. Edwards makes, I will say we cannot wait until the diagnosis is made because it is everlastingly too late. The nitrate of silver solution must be dropped in before the germs have had a chance to develop in the tissues. At that time there is no disease of the tissues and the germs are simply on the surface. In regard to this disease being absent from the country, the experience of every specialist, I think, will contradict that, because these cases come to us from the country at least as often as from the city. And suppose Dr. Sheddan has had 554 cases without a case of ophthalmia; suppose he has had a thousand, would it not be better to put in a few drops in the thousand cases than to have one case of opthalmia neonatorum? The statistics in the blind asylums, where this practice is not followed, show that ten per cent. of the inmates have opthalmia neonatorum.

DR. GLENN: Does every child having

ophthalmia neonatorum go blind? Do you mean, if you don't prevent it, you will lose the eye if it exists?

DR. SMITH: No, not always; but the great majority, even if properly treated, will become blind.

DR. GLENN: I wish to say I have never lost an eye, where I have had an opportunity to treat the patient properly.

DR. T. H. MARABLE, Clarksville, (closing discussion):—The discussion seems to have been so diversified that a man could take almost any course that he sees fit in the treatment of the new-born. As to resuscitation. I must confess, and I am very sorry in that confession, that I am not such a brilliant diagnostician as Dr. Happel, in deciding as to whether or not the child is dead in 20, 25 or 30 minutes. I would not be surprised, if Dr. Happel has discontinued trying to resuscitate children in that time, he has found them living, if he has not buried them too soon, for I have treated them an hour and a half and then laid them away and known them to be resuscitated. Certainly you can resuscitate children when they are seemingly dead.

Now as to Dr. Holtzclaw. Yesterday I was struck by Dr. Powell's statement that East Tennessee was God-forsaken, because I had been taught that East Tennessee was the pure part of Tennessee. I think the purity of the air was what led them to go to the polls without the poll-tax receipt. But he says the frequent diseased condition of their females would cause them to resort to artificial feeding. Well, I am glad to say this is not the case in Middle Tennessee. Our women are healthy enough to nurse their babies, unless they are too fashionable. I hate most awfully to have to acknowledge that fact, after being raised and taught what a healthy country East Tennessee is.

As to Dr. Powell. Dr. Powell says in North Carolina, where he practiced before the war, they would hang a piece of fat meat up from the floor for the little negroes to jump up and grease their throat with. I did not practice before the war, and can say nothing about that.

I can see no use of going further into this matter, except the eye trouble. I did not touch that through an over-sight. I began the practice of medicine in the country, have been in the profession eighteen years, and have seen but two cases of ophthalmia neonatorum. In neither was there blindness following. I do as a fact wipe off the face, but I must confess I would never follow the practice of putting foreign matter into the eye. The Doctor spoke of adhesive plaster. It was surgeons' plaster I referred to. Perhaps he did not clean the child thoroughly enough. If he will try that, and try a little longer to resuscitate the child, he will probably succeed better.

THE DAMAGE SUIT.

See Page 849.

DISCUSSION.

DR. MENEES: There is not one of us who is not more or less interested in this subject; almost all of you certainly much more so than I am, and the young members especially, who have their races in the main before them. Dr. Eve states in that paper correctly that the large majority of these suits are brought by pauper patients. He miggt have gone further correctly and stated that nine out of ten of them are brought by professional pirates. [Applause.] Sir, are there no means of protection against this sort of insidious and stealthy assault upon the members of the best profession, except possibly the theological profession, and the one which does the most charitable work, not only without gratitude, but absolutely with malice and prosecution at the bottom of it?

One time, Sir, during the life time of Dr. Eve's father, I was summoned from my couch to go see a woman, who had unfortunately sustained some accident on the way home from church. The messenger, who was a very bright young man,

impressed upon me especially that they wanted me and nobody else. I said, "You are mistaken about that, you want anybody else rather than me." "Well, she must have you and she will have nobody else." And he talked about it so convincingly and earnestly, I said, "Young man, there is a malpractice suit lying at the bottom of this. Go for Dr. Eve and get him." Very reluctantly the messenger went for Dr. Eve. In the ripeness of time the Doctor came to me and asked if I had any recollection of that case. "Don't you think, they have sued me for damages in that case!" I said, I knew from the beginning there would very likely be a suit for malpractice. Dr. Eve and Prof. Lindley were both sued.

Gentlemen, they lie in wait for you in the dead of night, come and arouse you from your slumbers, and with their oily tongue seduce you and rob you not only of your services but of your well-earned gains.

DR. W. FRANK GLENN, Nashville: I want to say a word in reference to the action of the profession when a law suit threatens. A patient almost invariably, before he sues for malpractice, goes to some Doctor he has confidence in and relates the case, with the statement that a physician did so and so. It may be wrong or ignorant, and the Doctor says it is wrong, and the patient immediately concludes to enter suit. I have always discouraged these patients. When asked if I would be a witness I have said, "No Sir, I will not." I would not go to the court house for any such thing. You can nine times out of ten say, "You have not paid him, probably, when you did send for him, and I will not testify against him." We should stand as a brotherhood, and I believe it is safe to say not a suit is brought without the advice of some professional man being asked

DR. T. K. POWELL, Dancyville: My knowledge of these cases is that they are usually gotten up by the shyster lawyers who haven't much to do. A plan was suggested in Chicago, viz., for you gentlemen of Nashville, for instance, simply to employ a first-class lawyer to take charge of these cases throughout the year, and pay him a salary. Dr. Eve and some others can stand these suits, but some of us cannot afford them. If we employ to take charge of these cases, we will stop them to a great extent at least.

DR. W. A. H. COOP, Nashville: I don't aid or abet a suit against the veriest quack. Not that I have any sympathy for the quack, but for the precedent. If you aid and abet a suit against a quack and obtain damages againt him, then some other individual will undertake to get damages against the honorable, upright and well-prepared physician. I well remember in the graduating charge, the late lamented Governor said, "Swear for no other; I will swear for you."

C. Holtzclaw, M. D., Chattanooga, presented a paper on

CHLOROFORM.

DISCUSSION

DR. T. L. MADDIN, Nashville: The subject is a very interesting one. There is one point I will speak of, and that is in reference to the dilatation or stretching of the sphincter ani. The most extraordinary experience I ever had with the administration of chloroform was when I was dilating the sphincter ani in performing an operation for hemorrhoidal tumors. The patient was a distinguished officer of the Confederate Army. I had been operating for some twenty minutes or half an hour, and thought I had removed all of the tumors. I insisted upon him taking ether, although I believed chloroform the best for that kind of an operation. I got through, except a little pimple of a tumor. I said to the Colonel, There is only a little pimple left and if I can clip it off the operation will be done. The gentleman administering the anæsthetic was a man of inexperience, but the Colonel said, "Don't be afraid of giving me chloroform. I was shot almost to pieces in the Confederate Army, and was filled with chloroform for three months. They just gave it to me by the gallon. I have taken chloroform enough to swim a boat." I whispered to the gentleman, to just give the Colonel a whiff or so of the chloroform. He didn't put a teaspoonful of chloroform on the inhaler. I felt the pulse just before I began to operate, thinking it was all right, but there was no pulse. I thought he was dead. They all thought he was dead. I was dilating the sphincter ani and yet that symptom occurred. It is true I was not dilating at that time, but I had been dilating for some time previous.

I worked two hours and a half to keep

the man alive. After we had kept up artificial respiration for an hour and a half without any apparent effort on the part of the patient to breathe, we stopped, and he made one inspiration. We waited for a second, but it didn't come. We then commenced our artificial respiration again, and after about five or ten minutes we suspended the artificial respiration and he gave us two inspirations and stopped, and stopped so long I was afraid he would never breathe again. We commenced the artificial respiration again, and absolutely it required two hours and a half to resuscitate him. He is living to-day.

DR. SMITH:—In regard to the use of cocaine in operations on the nose. The use of cocaine in chloroform narcosis has been considered especially dangerous. The symptoms from cocaine and from chloroform we would consider in the same way, and cocaine would be contraindicated when we use chloroform. I have never used cocaine and chloroform at the same time. I would suggest, as an anesthetic for the mucous membrane, a solution of antipyrin. With regard to the dilatation of the sphincter ani, I see that the suggestion is made to place a piece of ice in the rectum.

DR. GRADY: I have not had as much experience in the use of chloroform as Dr. Holtzclaw, yet I have used it and seen it used for 25 years, and I must say I have never seen any trouble from its use. I have seen some deaths following the administration of ether; whether from the use of ether I cannot say.

I have seen the section of the kidneys arrested after the use of ether, although not entirely arrested. So I want to commend highly and give my sanction to the paper of Dr. Holtzclaw. I would like to ask the Society one question with regard to the use of nitrate of amyl. I see some physician has recommended the combination of one ounce of nitrate of amyl with six ounces of chloroform, saying that will make it absolutely safe and effectually do away with any bad results from the use of chloroform. If any of the gentlemen have had experience with this, I would like to hear it.

DR. J. W. BRANDAU: I have recently had some experience with the combination of nitrate of amyl with chloroform. I saw a suggestion in the *Journal of Materia Medica*, that the proportion was very large so I combined about two drops of the nitrate of amyl to a dram of chloroform. In the cases I have used it, it has had a very happy effect. In the case of an inebriate, I kept the patient under about 30 minutes without any untoward result. But in plethoric cases I would think it not so good.

The Bacteriology of Rheumatism.

Dr. Saccaze (*Arch. Gen. de Med.*) has recently reported six cases of rheumatism which clearly indicate a causative relation of the staphylococcus to this disease. Dr. Saccaze remarks that "it is frequently possible, in cases of acute articular rheumatism, to discover in the history of the case evidence of a lesion preceding the pain, and other symptoms whereby infection with the staphylococcus might have occurred." In four cases of the disease, rheumatism occured consecutively after two attacks of sore throat in persons suffering from chronic hypertrophy of the tonsils. It is remarkable that these acute exacerbations of throat ailment are frequently observed in connection with the acute attacks of articular rheumatism. In the opinion of Dr. Saccaze, the general condition of the body which gives rise to the joint affection, occurs in these cases through the tonsils, which are constantly exposed to infection by the staphylococci which abound in the mouth.—*Modern Medicine and Bacteriological Review.*

Perityphlitic Abscess not Due to Appendicitis.

Homans (*Boston Medical and Surgical Journal*), gives the details of a case of abscess in the right iliac region occurring in a child 4 years of age. There was pain to right of and around the umbilicus, also distension of abdomen and tenderness. The pulse was 120, and temperature 103° F. A dose of oil produced only a slight movement. On opening the abdomen the healthy bowels were seen, and to the right of the umbilical region was a level surface of grayish color. This was the roof of an abscess, and on it lay the healthy appendix. The abscess was evacuated and recovery ensued, the appendix not being disturbed. Except for the youth of the patient and the fact that the appendix was normal, the case did not differ from others that are called appendicitis when operated on, and in which the appendix does not happen to be seen.

PERISCOPE.

IN CHARGE OF WM. E. PARKE, A.M., M.D.

MEDICINE.

Prognosis in Slight Amounts of Albuminaria.

Dr. G. V. Poore (*Lancet*), from the study of many cases concludes that the discovery of even a small amount of unsuspected albumen by the acid test of boiled acid urine should lead the physician to re examine the patient carefully, to be sure that some of the concomitants of such a condition have not been overlooked. A trifling hypertrophy of the heart, slight pallor, deficient body weight, slight increase of the tension of the pulse, ever so slight a puffiness around the ankles, tongue slightly furred or slightly tremulous, a florid complexion or other evidences of an old and perhaps forgotten syphilis, at once assumes a serious importance. If, after repeated examinations of the urine, the albuminuria is found slight and temporary, the patient otherwise looking strong and hearty, with no suspicion of intemperance and with no flaws in the family history, the prognosis is good. If the albuminuria is slight and permanent, the prognosis is grave in the majority of cases. When much albumen is continually found in the urine, the patient is in imminent danger, though Dr. Poore has had one such case in which the patient lived for twenty-six years. It should not be forgotten that albumen may be temporarily present in the urine of persons who afford no reliable evidence of kidney disease. In such cases it is the result of various disturbances, such as cold bathing, excessive exercises, injudicious diet, sexual excess, menstruation, leucorrhea, and other causes.

Do Not Lance the Gums.

So good an authority as J. Lewis Smith has recently spoken against the practice of lancing infants' gums. In a paper read before the New York County Medical Association (*Medical Record*), he said the belief prevails to a wide extent that the cutting of teeth is a common cause, not only of painful gums and poor appetite, but also of enterocolitis and other serious maladies, which are often allowed to run along until beyond the skill of the physician. Our ancestors in the profession were to blame for the wide-spread impression that much disease is due to dentition, since at one time it was a common custom to incise the gums. As to lancing the gums, he thought one could get along as well without it. If the gums were red and irritated, there must be some other condition to account for the irritation. He did not think the physiological process of normal dentition was to be interfered with any more than any other physiological process.

Sexual Debility—Their Causes.

Dr. T. R. Sturgis in a recent number of *Gaillards Med. Journal* formulates the following:

1. That the cases of sexual debility which are marked by imperfect erections and by premature emissions, are usually if not entirely due to hyperæsthesia of some portion of the urethra.
2. That masturbation has very little, if anything to do with it, beyond the fact that if indulged in to excess it may induce a tendency toward this hyperæsthetic condition, but this is no more marked in masturbators than it is in those persons who indulge to excess in the venereal act.
3. That organic stricture has little, if anything to do with it; but that associated with this hyperæsthetic condition there is an irritable condition of the canal which produces spasmodic contractions of the urethra upon attempts to pass instruments, oftentimes during the first act of micturition and at the time of connection.
4. That varicocele plays no unimportant part in these cases.
5. That neuralgia of the testis, if a cause of this disease, induces it merely as a secondary consequence to the pain which is one of the distinguishing features of this disease.
6. That tuberculosis, syphilis and gonorrhœa may also play their part and should all be reckoned with in summing up the causes which may induce this peculiar and depressing condition of affairs.

Hunger.

Many persons have noticed that even if hungry on retiring, it is an exception to have a feeling of hunger on awakening in the morning. It is probable that during sleep the functions of digestion being in abeyance, the stomach contracts, and this is probably why some persons cannot eat late at night. The empty stomach having no function to perform, contracts on itself and in the morning it requires some little stimulation for it to begin its daily work. This is why so many, especially invalids, cannot take a hearty breakfast and why in some countries the breakfast consists of a cup of coffee, and a second breakfast is taken at noon when the whole body is awake.

The hearty American breakfast strikes terror to the average European and the delicate French woman would probably faint at the sight of a beefsteak at breakfast. For those who can, it is a good plan to drink a little cold water on rising. It washes out the somach, takes away any mucous that may have collected there in the night and stimulates the digestive glands to give forth their secretion and prepare for that important act, digestion.—*Popular H. Magazine.*

Primary Peritonitis Due to the Pneumococcus.

At the same meeting Dr. Le Gendre, on behalf of Drs. Arnozan and Bassaet (Bordeaux), read a note, of which the following is a summary:

Primary peritonitis with pneumococci is so rare an affection that its existence in the adult has been denied; but we recently met with a case in a young girl of eighteen.

The pus, in this case, presented all the characteristics of that found in pneumococcic infections, viz., the greenish-yellow color, downy appearance, consistency, adhesion and fibrino-albuminous composition which distinguish the latter. Moreover, bacteriological examination revealed the presence of numerous disseminated, encapsuled diplococci resembling in appearance those described by Talamon and Frankel, and which were not decolorized by Gram's method.

Adding this observation to those published by various authors, there are in all eleven cases, of which only two were adults. Of the eleven patients, eight died, the mortality thus being about 73 per cent, which indicates that primary pneumococcic peritonitis is much graver than any other localization of this microbe. It is probable, however, that when the affection becomes better known and intervention more successful, this unfavorable impression will be greatly improved.—*N. A. Practitioner.*

A Case of Perforated Gastric Ulcer.

Kirkpatrick (*Montreal Medical Journal*), reports the case of a girl admitted to the hospital suffering from pain in the abdomen and shoulders. This pain started two days before and was accompanied by vomiting. The abdominal pain was particularly acute in the epigastric region. The patient was not vomiting at the time she was first seen. There was tenderness in the epigastric and innermost portion or the right hypochondriac regions. The belly was tympanitic. Cœliotomy was performed. The anterior wall of the stomach was slightly adherent to the parietes. The adhesions were broken down, gas escaping, and the lesion was found in the anterior wall of the stomach, a little to the right of the œsophageal line, and more towards the superior than the inferior gastric border. The opening was a little larger than a five-cent piece, and was closed with a continuous Czerny-Lembert suture, after trimming the ragged edges with a pair of scissors. A drainage-tube was inserted and the wound was closed. The tube was removed in twenty hours. Food was administered on the third day. The patient made an uninterrupted recovery.

Electrical Treatment of Red Noses.

Dr. Helling, *Med. Rec.*, says that a red nose is due to contraction of the arterioles and dilation of the veinlets. He claims to have cured a number of cases by the application of a continuous current of moderate intensity for five to ten minutes daily.—*Ex.*

Dangers of Thyroid Feeding.

Beclere remarks that the benefits to be derived from thyroid feeding in myxœdema must not make us forget its dangers; for thyroid juice poisons the heart, and may cause death by syncope. This has been found by experiment on the dog.

The writer fed an ape on fresh thyroid glands from newly killed sheep. The animal died in ten days. It had survived the same treatment when tried a month earlier.

It is said that an adult and one or two children have died in the Paris hospitals from treatment by thyroid feeding, and if this be so, it is to be regretted that the cases have not been published, so that practitioners may be put on their guard against a repetition of such occurrences. In connection with this mode of treatment the pulse is the best guide. Not only must its acceleration be noted, but perhaps still more its instability. Under the influence of the slightest effort, its frequency may be raised to 110, or even 160. At the commencement of treatment the patient ought to be confined to bed, or at least to his room, and he ought to be warned to avoid every exertion that might suddenly accelerate the heart's action. He ought to be kept under observation for some time after the treatment has ceased, because thyroid juice seems, like digitalis, to have cumulative effects. Some patients who died suddenly in England had taken no thyroid glands for some days before the fatal issue. The idiosyncrasies of patients are very various, and it is well to intermit the administration from time to time until the useful and safe dose of the remedy for the particular individual has been ascertained.—(*La Medicale.*)

Posture During the Growing Age

of children exerts a marked influence on their bodily development. Everyone is somewhat familiar with the physiological fact that the constant use of a muscle causes an increase in its size, while disuse causes it to weaken and become smaller. Recognizing the importance of this well-known physiological law, teachers and parents should keep ever in mind the effects of school life on the symmetrical and healthful development of the bodies of school children. A popular writer on such themes says:

There is a tendency among school children, especially among school girls, to assume habitual postures both in sitting and standing. The habit of throwing all the weight of the body on one leg produces a corresponding throwing of the upper part of the body toward the opposite side in order to establish the necessary equilibrium. This tends, of course, to curve the spinal column on which the upper part of the body is supported. In this position the body and all the internal organs are thrown out of their normal vertical position, and the force of gravity still further exaggerates this result. Thus the muscles of the neck are unevenly exercised in the unconscious balancing of the head upon the vertebral column.—*Popular Health Magazine.*

Effect of Muscular Overwork on the Heart.

As muscular exertion continues and the vessels of the muscles become dilated the flow of blood from the arteries into the veins will tend to become much more rapid than usual. The pressure in the arterial system will fall consequently, but that in the veins will become increased, and, unless a corresponding dilatation occurs in the pulmonary circulation, blood will tend to accumulate in the right side of the heart, the right ventricle will be unable to empty itself completely, shortness of breath will arise, and even death may occur. At first the right side of the heart is affected and the apex beat disappears from the normal place and is felt in the epigastrium; but the left ventricle also becomes dilated, though whether this is simply through nervous influence tending to make it act concordantly, or for some other reason, it is at present impossible to say. Severe exertion, even for a few minutes, may produce this condition in healthy persons, and when the exertion is over-continued it may lead to permanent mischief. More especially is this the case in young growing boys; and it is not merely foolish, it is wicked, to insist upon boys engaging in games or contests which demand a long-continued over-exertion of the heart, such as enforced races and paper chases extending over several miles. Intermittent exertion, either of a single muscle or of a group of muscles, or of the whole body, appears to lead to better nutrition and increased strength and hypertrophy, but over-exertion, especially if it continues, leads to impaired nutrition, weakness and atrophy. If we watch the movements of young animals, we find that they are often rapid, but fitful and irregular, and varied in character, instead of being steady, regular and uniform. They are the movements of the butterfly, and not of the bee. The varied plays of childhood, the gambols of the lamb, and the frisking of the colt are all well adapted to increase the strength of the body without doing it any injury; but if the colt, instead of being allowed to frisk of its own free will, is put in harness or ridden in races, the energy which ought to have gone to growth is used up by the work, its nutrition is affected, its powers diminished and its life is shortened. The rules which have been arrived at by the breeders of horses ought to be carefully considered by teachers of schools and by the medical advisers who superintend the pupils.—*Lauder Brunton in Br. Med. Jour.*

On Transmisibility of Cancer from Man to Animal.

M. Boinct, after a long series of experiments on the transmissibility of carcinoma from man to animals, states that after having made repeated inoculations on the rat, the rabbit, and the guinea-pig, he concludes that histologic examination of the lesions which resulted does not authorize him to pronounce in favor of such transmission. —*Semaine Medicale.*

Inflammation; its Nature and Significance.

Dr. J. Froehlich (*Aertz Rundschau*), as long as the organism is alive, it will react against every local irritation, that is, attempt to counteract the same if possible. If the irritation is slight, the force of resistence of the tissues will overcome it; if more pronounced than the force of resistence it becomes pathological, and the simplest form of inflammation results. Without inflammation, repair cannot take place, vital activity will cease, and destruction follows.

The real nature of inflammation consists in an active hypermia and an increase in the processes of metabolism. There is a dilatation of the arteries, later on of the veins, and last of all of the capillaries. The blood stream is at first accelerated, but very soon becomes permanently retarded on account of the choking of the capillaries with cellular elements. The white blood corpuscles will move slowly along the walls or the vessels or become entirely stopped, and then enter the tissues in a greater of less number, where they exert an important and active influence in destroying the germs of infection.

In the treatment of an inflammation the use of ice does more harm than good. We should not try to overcome the arterial congestion, but the venous engorgement, and for this various hydrotherapeutic procedures and massage are the best. Frequently the strengthening of the whole organism is more important than the local treatment, this being especially the case in chronic processes.

Prophylactic Treatment of Ophthalmia Neonatorum.

Dr. P Budin by long experience has found the Crede solution (nitrate of silver 1:50) effective in the prevention of ophthalmia neonatorum, but it often produces considerable swelling of the lids, with a moderate conjunctival suppuration on the second day after use. On account of these disadvantages other antiseptics, as phenic acid, corrosive sublimate, iodoform, etc., have been recommended. The author finds that a weaker solution of nitrate of silver (1:150) acts with almost absolute certainty in preventing the disease, and is free from the objections of the stronger solution generally applied. Among 2,004 cases treated there were only two cases of ophthalmia, and seven cases of secondary conjunctivitis. Patients are prepared previous to accouchement by having a bath and a vaginal injection of sublimate solution (1:4000). Immediately after birth the child's eyes are carefully wiped with cotton and one or two drops of a 1:150 nitrate of silver solution are instilled between the lids. The author has made this application to the newborn in his private practice for two years past, during which time no case of purulent ophthalmia has occurred. Only one case of mild conjunctivis was seen that recovered in a few days under simple dressing fluids.—*Progress Medical.*

Treatment of Cystitis in the Female.

John C. Hersler (*Univ. Med. Mag.*) the chief indications for treatment are:

1. To remove any discoverable sources of irritation which act through the medium of the urine. This may be effected by a milk diet, and a discontinuance of the use of acid, pepper, etc. Any mechanical source of vesical irritation should receive appropriate treatment.
2. The urine should be rendered bland by the use of a milk diet, the ingestion of considerable quantities of water, the administration of potassium citrate, if the urine be too acid, or of boric acid if it be alkaline.
3. Pelvic congestion should be relieved by hot vaginal douches, placing the patient in the knee-chest position; and the correction of constipation.
4. The inflamed cystic mucous membrane may be relieved by the administration of boric acid, salol, ol. santal, copaiba, or creosote by mouth; or the use of injections of boric acid, carbolic acid, or nitrate of silver in suitable strengths.
5. The patient's general health should be improved by tonics, etc.
6. Rest in bed, especially in all acute cases, is absolutely imperative.

While advocating direct local treatment for cases of cystitis which do not readily respond to ordinary therapeutic measures, the writer advises that it should be employed with judgment and caution.

The Micro-Organism of Chronic Rheumatism.

Schuller (*Medical Record*) has found a specific bacillus for chronic rheumatism. The organisms are described as measuring 2.6x0.85, and are constricted at the middle. They stain well with carbol-fuchsin, but are easily decolorized by acids. They are said to grow fast at 25°C. in the dark. All the ordinary culture media are fitted for their development. Schuller inoculated the joints of rabbits with cultivations obtained from human joints, and succeeded in producing a non suppurative arthritis analogous to the rheumatoid arthritis affecting man. The chronic rheumatism seems to be an entirely different disease from the acute, from which Schuller has only succeeded in cultivating staphylococci and streptococci, never the specific baccillus described above.

Electricity in Amenorrhœa.

Dr. Panecki, in the *Therap. Monatsch.*, says the *Medical Times*, lets the profession know that the faradic current is the most successful means of treating amenorrhœa. The poles should be allowed to act inside the uterus. The current can be increased at each sitting, and the treatments required, ranging from five to fifteen minutes, are all the way from five to thirty. The doctor had treated eighteen cases and cured them all. One was a married woman, aged thirty-one, who had never menstruated, though she had periodical headache, etc.

Presystolic Apex Murmur of Aortic Regurgitation.

Fisher (*Lancet*) cites a case, and remarks that a low-pitched presystolic murmur may occasionally be heard at the apex in cases of aortic regurgitation. The high-pitched, blowing diastolic murmur may possibly be audible from base to apex, and even in the axilla, but just at the apex a rumbling sound takes its place. It may be made to disappear by pressure of the stethoscope, and thus be overlooked. "In this instance the presystolic bruit was not low-pitched and rumbling, but of that loud, rolling character which reminds one of the sound produced by a flapping sail as it is filled by a puff of wind. Well marked though the murmur was, the mitral orifice proved to be of natural size." There was also present a presystolic thrill at the apex. Fisher also mentions that presystolic apex murmurs may occur unassociated with either mitral stenosis or aortic insufficiency, being due simply to adherent pericardium, and suggests that in both of these conditions simulating mitral stenosis the innervation of the heart may be, in some obscure way, affected, giving rise to the production of the murmur.

The Diagnosis and Theory of Morbus Basedowii (Graves's Disease).

Lemke (*Deutsche Medicinische Wochenschrift*) comes to the following conclusions concerning Graves's disease: (1) A patient suffers with Graves's disease as soon as delirium cordis and tremor are present. All other symptoms are consecutive and of secondary nature; they simply confirm the diagnosis. (2) The cause of Graves's disease is in all probability to be sought in a faulty chemical influence exerted on the blood by the thyroid gland. (3) Graves's disease, therefore, is no disease of the nervous system; one requires for its diagnostication no special neurological knowledge. He believes the diseased product of the thyroid gland to be a special muscle poison, the delirium cordis being the result of this poison exerted on the heart muscle, and the tremor the result of the same poison on the skeletal muscles.

Menstrual Agina.

M. Raymond Petit has been led to regard the sore throats of menstruation as caused by steptococci. They are generally benign, but may terminate in the formation of an abscess or give rise to facial erysipelas. The writer is of the opinion that women during menstruation should guard against infection by the use of antiseptic linen and by particular care of the mouth. Women, during all her genital periods (menstruation, accouchement) affords a specially favorable soil for the development of the streptococcus.—*La Medecine Moderne.*

Menstruation, Gestation and Small-pox.

Voight (*Volkmann's Samm. klin. Votrage*), has prepared a monagraph on the influence of Variola on Menstruation, Pregnancy, Labor and Fœtus. Small-pox, he says, causes congestion of the endometrium, both when the fever begins and when the rash appears; in consequence, menstruation or metrorrhagia occurs in the non-pregnant subject. Half the cases of pregnancy in small-pox patients vaccinated in youth end in abortion or premature labor. The pregnant woman's condition is desperate in confluent or hæmorrhagic small-pox. These two specially severe forms are very much more frequent in pregnant than in non-pregnant women. The mortality of pregnant small pox patients once vaccinated in youth varies between thirty and thirty-five per cent., but 50 per cent. of patients delivered while suffering from small-pox die. The danger of small-pox in pregnancy is found, as might be expected, much worse in women who have not been vaccinated. Nearly all the infants are lost, as they are either born very weak, or contract small-pox before or after birth. When an epidemic of variola occurs, prophylactic vaccination of all pregnant women must be practised, and, should an infant be born strong and healthy, it should also be vaccinated.—*British Medical Journal.*

Pigmentation in Amenorrhœa.

Lawrence (*Bristol Medico-Chirurgical Journal*) reports the case of a girl suffering from amenorrhœa with pigmentation. This became so marked as to suggest Addison's disease. She was treated with wine of iron, 1 drachm, and Fowler's solution of arsenic twice daily, burgundy in moderation, careful diet, the addition of milk, and her life regulated in accordance with general hygienic principles. This resulted in complete cure after many months.—*Therapeutic Gazette.*

The Improvement of the Results in Complete Hysterectomy for Carcinoma of the Uterus.

Mackenrodt (*Zeitschrift fur Geburtschilfe und Gynakologie*) believes that the operation of complete hysterectomy for carcinoma of the uterus does by no means offer absolute results, that the disease returns in more than half the cases operated upon. One cause of this unquestionably lies, as shown by the investigation of Winter, in the possibility of the inoculation of healthy tissue from the carcinomatous part; also, and particularly, has the writer concluded from the same investigations that the operation is not radical enough. Carcinomatous nodules are very frequently allowed to remain in the broad ligaments, and a necessary result is that the disease sooner or later returns. Mackenrodt has demonstrated this through the careful examination of a large number of extirpated uteri. The operator, he says, has believed that the incisions were made only in healthy tissue but the microscopical examination of removed organs show the infiltration extending to the line of incision. Thus, in order to improve the results of complete removal of the uterus for carcinoma, he believes that more tissue should be removed from the broad ligaments than is the custom. In accomplishing this the injury of the ureters must be carefully avoided. This last is attained by separating the bladder not only from the uterus, but also from the anterior surface of the broad ligaments. The bladder, with its attached ureters, is thus considerably separated from the uterus, and the tissue for a distance of an inch on each side of the cervix can easily be excised. The injury of the ureters after this procedure is scarcely to be considered. The separation of the bladder and ureters from the anterior surface of the broad ligaments can be accomplished quite as well in vaginal as in abdominal hysterectomy. Where there is a rigid vagina, large uterus, and advanced carcinoma, Mackenrodt usually does abdominal hysterectomy.

Urination after Labor.

Dr. N. Recht (*Rev. Internationale de Bibliog. Med.*) in a thesis has made a study of micturition in the lying in period. He comes to the following conclusions:

1. Urination, after labor, in the majority of cases, follows spontaneously.
2. Catheterization is but exceptionally required; if it be necessary, it should be deferred as long as possible.
3. It is only indicated when the bladder assumes abnormal proportions, or if retention occurs.
4. Catheterization is liable to occasion two evils—cystitis, in spite of all precautions, and dependence of the bladder for a time upon the catheter.

Dangers of Massage of the Uterus.

M. Pozzi presented the specimens from a case illustrating the injurious effects of massage in suppurative lesions of the appendages. A patient suffering from metritis and double salpingo-ovaritis, after an attack of pelvic peritonitis diagnosed as hæmatocele, was treated by massage, the operator being a skilled one. The treatment was badly borne, and caused no improvement. M. Pozzi afterward performed laparotomy and extirpated both tubes, which presented the external appearance of pyosalpinx. Outside of the left tube there was a small purulent area. On opening the tubes the left one was found to contain blood and the right a rose-colored pus. Under the influence of the pressure exercised during the massage, rupture of the vessels and hæmorrhage in the tubes had evidently occurred. The same pressure might also have driven pus out of the tube, thus explaining the purulent area found on the wall of the pelvis at the outer extremity of the tube. M. Pozzi believed that massage should be reserved for

chronic cases in which there was no suppuration.

M. Bouilly reported several cases illustrating the bad effects of massage. A woman with a neoplasm in the posterior cul de-sac was submitted to massage, when suppuration of the tumor took place, causing the death of the patient. Another case of simple retroversion suffered the most painful symptoms after massage, and a third was confined to bed from its effects, though she had only a slight ovarian affection. The indications and contra-indications of the treatment should be clearly defined.

M. Lucas Championniere had also observed similar ill effects, and had been recently obliged to perform laparotomy in one such case and hysterectomy in another.

M. Richelot had performed hysterectomy on a patient who had undergone treatment by massage with only temporary relief.

M. Routier stated that he had made use of massage in his practice for the past eight months with good results, but that he employed it only in cases in which no lesion existed.

M. Monod regarded the method as an excellent one when suppuration was not present, and in this opinion the members generally concurred, stating that they wished only to call attention to the dangers of its abuse and the necessity of intrusting the cases to competent persons.—*Universal Med. Jour.*

GYNECOLOGY.

New and Speedy Method of Dilating a Rigid Os in Parturition.

At a meeting of the Obstetrical Society of London, Dr. Farrar (Gainsborough) gave the details of two cases in which he had used a 10 per cent. solution of cocaine as an application to the rigid os. In one case he had applied the cocaine after endeavoring vainly to relax the cervix by means of chloral, bromide of potassium and morphia, and the most persistent attempts at digital and mechanical dilatation, with and without chloroform. He decided upon incising the os, and used the cocaine to this end. After five minutes he introduced the finger as a guide to the scissors, and, to his surprise, found the os widely dilated. In the second case, a primipara, forty-eight years of age, he used every effort, as before, to produce relaxation, and waited three days before making the application of cocaine, which was immediately successful. In four minutes the os had yielded. He considered the dilatation to be due to the cocaine in both cases. Dr. Armand Routh said that Dr. Dibbs, of Shankin, had recommended cocaine as relieving the pains of the first stage of labor, and that Mr. Head Moore advised cocaine and boric acid pessaries in cases of rigid os. He himself had found it useful. The president, Dr. G. E. Herman, said that two cases were rather a slender foundation upon which to base a conclusion, but if Dr. Farrar's results were confirmed by further experience, he would have made a valuable addtion to our obstetric resources.—*The Lancet.*

Immediate Trachelorrhaphy.

There are always old questions in gynecology that will be resurrected and discussed and ardent supporters for both sides are not wanting. Dr. Boldt recently advocated waiting for some time after childbirth before sewing up lacerations.

This Dr. A. Palmer Dudley opposes in the *American Journal of Obstetrics* and asks a number of questions bearing on a comparison between immediate and intermediate trachelorrhaphy, and after citing a number of cases in support of his side, gives for the purpose of emphasizing his remarks the following summary:

1. That suturing the lacerated cervix properly immediately after delivery will result in primary union of the same and prevent many of the evils that follow in the wake of a union by second intention.

2. That the fear of septicemia attending the manipulation of the cervix for the same, and the introduction of poisons which will induce septicemia at the same time, is an unfounded one, and would be dissipated by giving such work a proper test.

3. That it is a method of procedure more justifiable than an immediate repair of the perineum, the latter of which the profession of to-day universally advocates.

4. That the securing of primary restoration of the laceration hastens involution, prevents subinvolution and the various forms of displacement which are induced by it in such an over-weighted organ.

5. The catgut is the proper suture and perfectly safe and reliable when properly prepared.

THERAPEUTICS.

The Rational Treatment of Diphtheria.

Local Treatment. 1. Thorough disinfection with peroxide solution, rendered neutral with bicarbonate of soda. 2. Administration of freshly prepared pineapple juice, either alone or with the tincture of the chloride of iron, if a condition of anæmia be present. 3. Application of papoid, either by insufflation of powder or painting with strong solution.

Constitutional Treatment. 1. Alcohol given in heroic doses. 2. Hypodermatic injections of strychnine pushed until there is exaggeration of the deep reflexes. 3. Concentrated nutritious diet.

Wind Colic of Infants.

Dr. G. C. M. Godfrey in the *Medical Record* suggests the following:

Extract zingiberis fluidi,	c.c. 6 (ʒ iss)
Tincturæ asafœtidæ	c.c. 12 (ʒ iij)
Aquæ menthæ piperitæ	
Aquæ cinnamomi,	aa c.c. 30 (ʒj)
Syrupi simplicis,	q. s. ad. c c. 120 (ʒiv)

M. Sig.—ʒ j (c.c.4) t. i. d. in water before meals.

Of course, the practitioner will change the quantities and ingredients to suit each case; it is very hard for an infant to take.

ORIGINAL ARTICLES.

A PLEA FOR EFFICIENT LEGISLATION REGULATING MEDICAL PRACTICE.*

PERRY H. MILLARD, M. D., ST. PAUL, MINN.

During the last decade no question in medical sociology has attracted greater attention than medical education. The requirements of our colleges not being upon a par with those of other countries, nor with other departments of education in this country, it was but natural that the profession as a whole, the medical press, and organized bodies of medical men, should join in a demand for needed reforms. During the formative period of our history it is but natural that abuses should have arisen in methods of education and obtain a firm rooting. A spirit of criticism exists that will not subside pending the definite determination of a question of such vital interest to the profession of the country.

As a nation during the first century of our history, we have established a system of common school education that challenges the admiration of the civilized world. It is a subject of regret, however, that in certain advanced lines of education our methods have proven most defective. This is true of medical education; a system having secured foothold with us that is indeed anomalous.

Having no support other than the fees of students; without university or college connection; without support from the state, generally accorded other systems of education; without restraining legislative enactments; without laws regulating the granting of charters for purposes of medical instruction; it is indeed little wonder that at the end of the first century of our history as a nation, chaos should reign supreme.

The agitation of the question of medical education is bearing fruit however, in that a majority of the schools situated in the northern states demand at the present time evidence of preliminary fitness before matriculation, and that in a period of five years all colleges known to the writer have extended the period of time of study; with a change of the minimum length of term from five to six months. After the present year every medical school of recognized standing will require attendance upon four courses of lectures in different years, each course, of six months' duration before conferring the degree of M.D. The reforms thus far accomplished have only been secured in the face of determined opposition at the hands of the representatives of the low-grade institutions. Future opposition will result in disaster to the participants. Professional sentiment

*Read before the American Academy of Medicine, at Baltimore, May 6, 1895.

is decidedly with those schools now operating under the advanced curricula. This is particularly manifested by the increased number of matriculates in the last three years at schools operating under the four years' course. The fiscal matriculation at the University of Pennsylvania and Columbia is, approximately, eight hundred, Harvard five hundred, and others in proportion; while that of the recognized low-grade institutions has sensibly fallen off.

Notwithstanding the trend of public opinion, we are firmly of the conviction that our only safety consists in the establishment of efficient legislative acts in substantially every state. The high-grade schools are undergoing a period of evolution and are determined to inaugurate greater system in methods of work; with low-grade schools little evidence is at our command pointing to improvement.

The elevation of the standard of requirements in the latter class of schools have seemingly been entirely in response to the requirements of the respective state boards of medical examiners.

The indifference of the profession to methods of medical education has been far reaching in its pernicious influences. Blinded by our own shortcomings we did not awaken to a realization of our environment until our interests were greatly jeopardized. We found ourselves drifting, in the estimation of both the public and profession, towards a condition of professional inefficiency, not unlike that of French medicine in the seventeenth century, so graphically described by Moliere. One of the greatest evils of our system was the flooding of our ranks with a horde of poorly educated practitioners far in excess of our legitimate demands. The latter assertion is convincingly illustrated by the statistics gleaned from the recent excellent paper of Professor Pepper on Medical Education, affording comparative statistics relating to the proportion of practitioners to the population in different countries of the globe.

TABLE INDICATING THE PROPORTION OF PHYSICIANS TO THE POPULATION.

Austro-Hungarian Empire	1	to	5,857

It will be observed from the above that the proportion of practitioners and the number of schools are greatly in excess of other countries. Medical colleges in foreign countries are likewise independent financially, being, as a rule, directly supported by the state or possessing a direct university connection.

An investigation of this subject reveals beyond the possibility of successful controversion that the most efficient profession is found in those countries protected by efficient legislation; while a correspondingly low standard of professional fitness exists in countries not similarly protected.

At one time considerable opposition existed to the regulation of medical practice by legislative enactments. With the defeat of attempts to destroy the effects of this form of legislation by litigation, and the moral support afforded by the recent decision of the Supreme Court of the United States and Supreme Courts of the several states, as well as the apparent benefits from the successful operations of the law in a large number of states, it is pleasing to note a decided change of sentiment in favor of this form of legislation.

The existing opposition to this form of legislation is greatly disappearing, being greatly confined at present to the charlatan, the faculties of a few of our low grade schools and the public press. We can trace the existence of statutes regulating medical practice from the thirteenth century; in the year 1237 licenses were only obtainable in Italy upon attendance at medical lectures for a period of five years, with preliminary entrance requirements demanding three years' work in philosophy.

The first degrees in medicine were evidently conferred in Italy in 1384. Laws

regulating medical practice have existed in all civilized countries for many centuries. It is unfortunate that in this country the diploma has been given a legal interpretation; in foreign countries it is simply an evidence of scientific value. With the advent of statutes regulating medical practice this custom upon the part of the courts is becoming abrogated. We cannot but conclude that in the older countries we have a superior profession in point of intelligence, with a more desirable environment; while with us we have, as a whole, men somewhat inferior in their preliminary training, a number triple that of any other country and a professional environment most undesirable.

The essentials of efficient medical legislation will incorporate the following features:

(1) The adoption of more rigid rules governing the admission of students to medical schools.

(2) The determination of the applicant's fitness to practice by an examination upon all the branches of medicine.

(3) The right to refuse or revoke licenses for unprofessional or dishonorable conduct.

(4) An adequate penalty for violation of the provisions of this variety of legislation.

(5) The boards of examiners to be appointed by the Governor, with proportionate representation by different schools of practice.

In support of demands for an adequate entrance requirement, it is conceded that medicine is now more nearly practiced from a scientific basis than at any time in its history. Without adequate preliminary fitness the broad field cannot be grasped nor its practice entrusted to persons without well trained minds.

Persons contemplating medicine as an avocation should give the scientific branches particular attention in preparation. A thorough course in the scientific department of our better equipped colleges or universities will permit of the successful accomplishment of the course now provided in the four years' curricula in a period of three years. I fully concur in the position taken by Professor Vaughan, however, in that the classical course does not prepare the student in a manner that he can safely abridge the work now required in the four years' curricula. The necessity of a thorough college training is more apparent now than at any previous time. While an immediate attempt, looking to the demand as above suggested, would probably meet with defeat, I am of the opinion, however, that by concert of action we can secure the adoption at this time of an elevation of the standard of fitness, requiring a college or university matriculation, or its equivalent, of all students wishing to commence the study of medicine. If the student cannot furnish a matriculation ticket from a recognized college or university, he or she should be required to undergo an examination that would admit to such course.

Under existing relations we cannot safely entrust this examination to the representatives of the teaching body. Except in a few of our high grade schools the entrance examination as at present conducted has been a farce. The factors leading to this condition are the same as outlined earlier in this paper. It is the result of college competition with an unnecessary multiplication, in recent years, of the number of teaching bodies. It is my judgment, based upon a somewhat varied and extended experience, that a majority of the schools in this country exist to serve the personal interests of the respective faculties rather than to serve the legitimate demands of the people. About twenty-five per cent. of our schools have a matriculation of less than sixty pupils.

The determination of the fitness of the student to commence the study of medicine should be placed in the hands of a body of men entirely disinterested. I know of no body better qualified to superintend the execution of this important trust than a state board of medical examiners. If not such a body, then a committee composed of members of a faculty of a college or university.

The minimum of entrance requirements should be uniform between the different states. Under the operations of the New York law regulating the examination of students commencing the study of medicine, much good is being accomplished. I desire to urge upon the profession the necessity of provisions in future acts looking to a rigid protection of the gateway to the study of medicine.

Having submitted satisfactory evidence of preliminary fitness, only such persons

should be admitted to undergo the professional test as have received their course of professional education at schools of medicine whose curricula of requirements are acceptable to the respective boards. A minimum of requirements, both as to time and teaching facilities, are as essential in measuring professional fitness as it is for similar purposes in universities, colleges, and our public school system. A school should not be recognized unless it is working under a minimum that will assure the graduation of a class of persons that can safely be entrusted with the care of the sick. In arriving at a conclusion upon this most important function I desire to particularly impress upon the members of these boards the fact that medicine as at present understood and practised is radically different from that of a few years ago. To comprehend requires years of study and a training in laboratory methods and surgical technique that can only be grasped when afforded by a person trained in methods of medical pedagogy. The clinical and laboratory facilites of many of our schools are shamefully inadequate. Several colleges known to the writer having operated for years with substantially no assets. It is the duty of each board to enquire fully into the facilities of each school represented by graduates who are applicants for degrees.

Having determined upon the fitness of the school to afford satisfactory courses of medical instruction, applicants holding degrees from such institutions should be admitted and a further test of fitness demanded by requiring an examination upon all the recognized branches of medicine. These examinations should be conducted by numbers, be scientific, and of sufficient severity to assure the public a thoroughly educated profession. Students from the respective schools of practice should undergo an examination upon the same questions, no necessity existing for questions not primary in character.

Licenses should not be refused or revoked for other than gross unprofessional or dishonorable conduct. In criminal cases it is not well to anticipate the processes of criminal law. The latter feature of our legislation has been instrumental in protecting the people from the professional charlatan in several states. Its provisions should be incorporated in all statutes regulating medical practice.

Owing to the difficulty in securing indictments and the consequent tardiness of legal processes the penalty for violations of the provisions of this form of legislation should be by penalties imposed by a justice or a municipal judge; the latter method has given satisfaction as far as I am aware. Reasonable efficiency upon the part of the officers of these boards have been awarded by a full compliance with the provisions of this form of statute in all instances. The Governor should have the appointing power, being responsible for the successful operations of the different state boards. Experience satisfies us that the so-called mixed boards are doing satisfactory work and operating in perfect harmony. Seemingly no excuse exists for the duplicate boards operating in a very few states. At present approximately thirty states possess legislation regulating medical practice. Seventeen states have a form of statute that fails to recognize the diploma as evidence of fitness to practice; consequently they may be classed with those states operating under efficient acts. In the latter class of states I particularly desire to call your attention to the results of work thus far accomplished. In a paper read before this learned body, at Detroit, Michigan, in 1892, I suggested the future influences of these boards as most important in shaping the future medical education in this country. I submit data at this time confirmatory of the position then taken and reaffirm my former suggestion that future legislation will in a great measure determine and govern the work of the teaching bodies of the country.

I am deeply indebted to the officers of the various boards for courtesies extended and regret that space forbids reference to many suggestions and conclusions arrived at in the work of the different boards.

Data have been obtained from the following named states: Alabama, Minnesota, Maryland, North Dakota, North Carolina, New York, New Jersey, Virginia, and Washington.

The subjoined table indicates briefly the work of these boards.

State.	Examined	Licensed	Rejected	Per Cent.
Alabama.....	647	558	89	0.862
Maryland.....	150	105	25	0.806
Minnesota.....	641	499	142	0.778
New York.....	967	797	170	0.824
New Jersey....	447	417	30	0.955
North Carolina	615	508	207	0.71
North Dakota.	81	76	5	0.938
Virginia.....	835	613	222	0.734
Washington...	207	167	40	0.806
Totals.....	4670	3740	930	0.822

It will be observed that of four thousand six hundred and seventy persons examined but eighty-two and two-tenths per cent. were successful in securing a license. The nine hundred and thirty unsuccessful applicants have, we doubt not, principally located in states not protected by this form of legislation.

I am pleased to direct your attention to the good work of the Minnesota board. The first act regulating medical practice in this State became operative in March, 1883. It was the form of legislation at present in force in Illinois. It was in operation five years, being supplanted by the present law. The present act requires an examination of all persons commencing the practice of medicine and as amended by the last legislature, the minimum of requirements is changed, demanding that all graduates of later date than 1898, furnish satisfactory evidence of having attended at least four courses of lectures in different years, of not less than six months duration each.

We have in Minnesota a practical illustration of the position taken in my former paper: "that in medical legislation we have the only solution of the problem of higher medical education." Having drafted these bills and by force of circumstances been somewhat conspicuously aggresive in urging their enactment, I have, in consequence, witnessed their operations with some concern and interest. The result is all that the most sanguine could have anticipated. In a period of twelve years the proportion of physicians to the population in Minnesota has been reduced from one practitioner to every six hundred and fifty in 1883 to one to every one thousand in 1895. The State has been substantially rid of the travelling charlatan. The present able secretary, Mr. McDavitt, informs me that the medical census just completed is accurate and that the present operations of the law is quite faultless. We therefore conclude that in one State at least the number of physicians has been reduced to a number commensurate with the demands of the people.

The work of the New York board is attracting considerable attention. Notwithstanding pronounced opposition and many embarrassments the act is destined to strengthen the character of the profession in this state. From advance sheets kindly furnished for use in this paper, I observe the following verification of a position taken by the Secretary, James Russell Parsons, in his 1893 report. He reiterates that the records of the past year conclusively prove the position taken in 1893 report, "That the new law proves a barrier to the ingress of the incompetent, has operated to raise the standard of preliminary education, improve the methods of teaching and terms of study of the different schools of medicine."

The following resolution from the president and secretary of the board to the State Medical Society is significant and should meet the approval and support of every member of the profession of this great state, "*Resolved*, That in the opinion of this Board the best interests of the public and medical profession would be materially advanced by gradually increasing the minimum of requirements as to general preliminary education till no candidate be entitled to matriculate in 1897 at a degree granting medical school in this state, that has not completed at least a full high school course."

I am pleased to note that this bill has already passed the senate in New York and is in a fair way of becoming a law. If it becomes operative it will operate to improve the character of matriculate in New York schools and will be followed by similar legislation in other states. Greater coöperation is necessary between different state boards, as it is essential that harmony of policy exist as far as practicable. As in foreign countries their relations to the profession and teaching bodies is most important, their functions being that of professional censors of the conduct of the members of the profession, and guarding at the same time the avenues of entrance to professional work. It being the duties of these boards to protect the people from professional incompetency and charlatanry the duties are briefly comprehended in the performance of the following duties: 1. In establishing a minimum curriculum for all colleges whose alumni apply for a license to practice. 2. The individual examination of all persons wishing to practice medicine in the commonwealth. 3. A professional censorship, granting the right to refuse or revoke a license for incompetency and gross unprofessional or dishonorable conduct.

As this form of legislation becomes more fully understood and appreciated by

the better class of schools, it will be observed as one of the most certain and reliable avenues of placing before the profession of the country the character of work being done in all colleges whose alumni apply for a license. A school doing honest work has little to fear at the hands of these boards; upon the contrary, as suggested in my former paper, it will be found that the proportion of applicants able to pass successful examinations will be a certain index of the character of instruction afforded students in the respective schools.

While the proportion of applicants successful is only eighty-two per cent., it will be found that from the schools heretofore operating under a high grade of requirements that, thus far at least in the work of these boards, nearly all graduates are successful in obtaining a license upon examination. In substantiation of this conclusion I again submit data, using therein the same schools as in my former paper.

The following table indicates the proportion of students successful on examination from alumni of schools heretofore operating under three years' curricula:

Colleges.	Examined.	Licensed.	Rejected.	Per cent.
Harvard	31	31	0	1.000
Columbia	123	118	5	.952
Univ. of Penna.	126	123	3	.976
Univ. of Michigan	83	78	5	.940
Northwestern Univ.	26	22	4	.846
Univ. of Minnesota	149	148	1	.992
Totals	538	520	18	.964

I cannot but conclude, gentlemen, that efficient medical legislation will operate to bring about the following results, as applied to the profession and public:

1. It will protect the people by affording a profession of greater intelligence.

2. It will suppress charlatanry.

3. It will reduce the number of persons practising medicine to a number commensurate with the demands of the people.

4. It will reduce the number of medical colleges, at present far above legitimate demands.

5. It will raise the general standard of professional fitness, assuring us a professional prestige in the future becoming the most important of the learned professions.

In conclusion, we appeal to the profession to renew their efforts in securing efficient medical legislation, believing its operations will result most beneficially to both the public and profession.

DRIFTING, WHO, HOW, WHITHER.*

LEARTUS CONNER, A. M., M. D., Detroit, Michigan.

The study of medical sociology exhibits a drifting in the matter of consultations. Rightly considered, the medical consultation is the "holy of holies" of associated work. He only can enter it aright, who, in the words of the Great Teacher, "hath clean hands and a pure heart; who hath not lifted up his soul unto vanity, nor sworn deceitfully."

Its history shows that the medical profession has ever taken the greatest interest in the qualifications of those seeking its fellowship. Not all calling themselves "doctors" have been admitted within its fold and many have been ejected therefrom who have entered by ways other than the strait gate.

Because of its jealousy of the proper character of its membership, the laity have termed the profession intolerant, bigoted, and narrow—so little has the world ever comprehended the sacred trust assumed by the physician.

The medical profession holds as sacred all knowledge acquired in the performance of its duties; it suffers in silence that the sick may recover health; it endures misrepresentation and obloquy because its nature and purpose are exalted above popular comprehension; it must be clean in thought, pure in life, and unselfish in work, if it would most effectively accomplish its purpose. Hence the necessity of ever keeping its ranks free from those lacking these qualities.

Differing standards of admission to the

*A paper read before the American Academy of Medicine, at Baltimore, May 4, 1895.

medical profession have prevailed in succeeding ages, different countries, peoples, and civilizations; but each has had some standard for both admitting and expelling members. No physician was ever burned at the stake by the medical profession for holding diverse views on matters of medical theory or practice, but many have been ostracised and regarded with contempt.

The standards of professional association are partly written, but more generally unwritten. Our written standard was adopted in 1847, but our unwritten one traces its origin to the first medical-man, being inherent in the nature of the medical profession—a part of the medical training. The son absorbed from his father, or the student from his preceptor medical knowledge, morals, and etiquette, and transmitted the same to their sons or students. Thus from hand to hand, mouth to ear, hand to eye, the real standard by which we accept or reject professional fellowship, has come to us as a direct personal testament from generations far antedating the earliest historic record.

The Roman Catholic Church regards the medical profession as *the* profession, all else but fragments, and in this respect it concurs with the estimate of itself by the profession. It is a gigantic tree whose germ sprouted when human beings first needed relief from suffering, whose leaves have been for the healing of the nations, and under whose sheltering bows the worn and distressed are protected from the scorching heat of life's physical diseases. The question before us is what shall be the relations of the medical profession to the "sects" and "isms" as homeophathy, eclecticism, etc? The code of ethics adopted by the American medical profession in 1847 makes the specific statement, that all professional association with members of these sects is derogatory to the medical profession. To "aid or abet" in the education of the believers in these sectarian views is also regarded with similar disfavor. For many years some have doubted whether ostracism was the wisest method of dealing with these sects. The number of doubters has, from year to year, so multiplied, that the student of medical sociology notes the change with increasing interest. He is led to inquire whether this drifting, starting in city and country, upon the mountains and in the valleys, from thousands of active centers scattered throughout the entire land, will finally lead the profession, to unitedly accept some method of dealing with medical sects, creditable to all and promotive of the best interests of the profession and humanity, or cause it to return to the primeval principal of an honorable fellowship, thoroughly trained in medical science and art.

Of this drifting we briefly note a few illustrations.

First in the matter of medical education.

When all medical colleges were manned by regulars, homeopaths and other sectarians obtained their scholastic education at these schools. Later the sectarians were able to educate their students in their own colleges, hospitals and dispensaries. When medical departments were established in state universities, the sectarians sought a position in the same, that they might teach their peculiar view. Notable among the institutions where this end was sought is Michigan University. Shortly after its foundation the homeopaths induced the State legislature to instruct the board of regents to place in the regular faculty a professor of homeopathic meteria medica and practice of medicine. For many years the agents refused to accede to this instruction; nor did they yield until it became an alternative of a sectarian professor or no university appropriation from the legislature. At this juncture the Michigan State Medical Society arose against the alliance and protested with such force as to cause the authorities to pause. The matter was at last carried to the American Medical Association and settled by the passing of a resolution to the effect that it was as derogatory to educate sectarians as it was to consult with the same after they were educated. The regents now set up a distinct homeopathic college (on paper). The phrase on paper is used because the homeopathic students still continue to be taught by regular teachers in the following subjects, *viz.*, chemistry, physiology, anatomy, bacteriology, hygiene, physiological chemistry, physics, pathology, histology, etc. That the regular professors should not be compelled to sign the diplomas of sectarians a new scheme of issuing university diplomas was adopted, by which no professors names appeared

thereupon but only those of the president and secretary. It will thus be seen that in spite of the resolution of the American Medical Association, the regular faculty have been and are constantly engaged in educating those whom they know to be sectarians in medicine. As this arrangement is universally acquiesced in by the profession, it is clear that in the matter of educating sectarians there has been a great drifting.

Of interest in this connection is the present agitation respecting the Homeopathic Medical College at Michigan University. Under the arrangement described this college failed to commend itself to the homeopaths, so that the members of this sect practically repudiated it. Hence its classes so diminished as to compel the regents to seek some other method more satisfactory to all parties. The plan which thus far has seemed to meet the wishes of the regular faculty, the board of regents, and a portion of the homeopathic faculty was the abolition of the so-called Homeopathic Medical College and the placing of a professor of homeopathic materia medica and practice of medicine in the faculty of the regular school. The final decision has not yet been announced. But that the deans of both the regular and homeopathic faculties, and the regular physician on the board of regents should unite in seeking to place on the faculty of the regular school a homeopathic professor, is significant of a drifting quite startling, and the more so as no public protest has been made against it by the regular profession. Other State universities than that of Michigan having medical departments are arranged along similar lines. These are all more or less responsive to the demands of the popular will, and this will, generally speaking, demands the full recognition of one or more of the "pathies" and "isms."

The first extensive revolt against the written law under consideration occurred in New York. It was preceded by an extremely bitter conflict and caused not a few ripples in the American Medical Association. The result of this revolt was that the friends of the written law established the New York State Medical Association and retained their allegiance to said law, while the opponents captured the old State Society, abrogated the written and returned to the unwritten law. To many this seemed a revolutionary proceeding, but when it is remembered that the revolting faction simply returned to the first principles of the medical profession, principles which satisfied the profession during thousands of years, the matter assumes a different aspect. The reformers only abrogate the written law of 1847, preferring the larger individual liberty of the profession anterior to that date. Previous to this, Massachusetts had a contest along similar lines, which resulted in affording sectarians equal rights with regulars, and turning popular prejudice against the medical profession.

The Mississippi Valley Medical Association gives its members entire freedom in the matter of consultations. Other medical societies in other places have taken similar action, notably in Chicago, Cleveland, etc.

An extensive knowledge of the habits of prominent physicians leads to the conclusion that a fat consultation fee is rarely refused because the attending physician is a sectarian. Personally the writer has often been told by colleagues that he was a fool because he regarded it a matter of gentlemanly honor to obey the spirit and letter of the law of consultations while he retains membership in societies having this law as a condition of membership.

Another marked illustration of this drifting was seen when a committee of its own appointment reported to the American Medical Association that it favored such alteration of the code of ethics as would permit consultations between all physicians properly educated, legally qualified to practice medicine, and of honorable reputation in the place where they live. When it is remembered that the committee so reporting individually obeys both the letter and spirit of the code bearing upon this point, it will be evident that their report indicates a drifting of the medical profession.

This drifting is farther seen, in that regulars and sectarians work side by side on boards of health, state and local, and on boards of other state institutions. This very imperfect sketch shows that, whether we like it or not the fact cannot be disguised, the professional relationships of regulars and irregulars are, at many points, multiplying and extending. If, finally, through these relationships the

sectarians shall be swallowed up by the medical profession, history will simply repeat itself. Within the memory of living physicians, specialists of all sorts were ranked as "irregular," and with them were classed "practitioners of massage," "electro-therapeutics," "hydro-therapeutics," etc. Now work in these fields is regarded as the most honorable, and the workers receive the largest returns in money, honor, and fame.

Whither does this drifting tend? The history of the past and the logic of existing social forces point to but one result; *viz.*, the absorption of all ideas that are true and helpful, and all persons who are honest and of good report into the medical profession. To this end larger liberty will be accorded the individual physician. He will be permitted to choose his professional associates from among those whom he knows to be properly educated, legally qualified to practise medicine where they reside, and of good report. Qualifications other than these will be regarded as purely local and temporary in their necessity and temporary in their existence, and to be controlled entirely by the individual physician. It were wiser to object to consultation with a physician because of known ignorance, lack of skill, dishonest methods, or disreputable character, than because of his sectarian name. Objection on the first ground is readily understood by any layman, but objection on the second fails to commend itself to most persons, and not infrequently brings the objecting physician into discredit.

The medical profession originated in the effort to systematically relieve human suffering and promote human health. Amid the glimmerings of dawning science, it jealously guarded each addition to its knowledge and incidentally contributed largely to the advancement of science. In every age parasites have sought to ally themselves with the medical profession that they might use its resources to plunder a suffering, credulous humanity. To exclude such parasites from the profession has ever occasioned perplexing thought, and for this purpose the unwritten custom of centuries was maintained, and to add still more in the same direction, in 1847, the American Medical Association adopted the written law of consultations now in force. But from the facts presented it is clear that at the present this law fails of its benificent design. Large bodies of physicians no longer regard the written law as in accord with the nature of the medical profession, and believe that this law should either be abolished or made to accord with the changed condition of our environment.

Apparently, if the profession is to present a united front to the world on this matter, a new statement must be made, satisfactory to the majority. All agree that the profession should be kept intelligent and clean, but all do not now unite upon a practicable method for attaining this end. Until such a method is devised and adopted with substantial unanimity, the drifting will continue; a drifting from a position incomprehensible by the laity towards one clear to every person; a drifting from a position calling for defence and explanation, towards a vantage ground commanding the entire field; a drifting from an indefinite standard towards a definite one; a drifting from a position affording no hope to those outside its circle, towards one giving hope to every intelligent, honest practitioner; a drifting from a position which loses the good work done by institutions other than its own, towards one in which it can absorb all good work, wherever done, and all good workers wherever trained; a drifting from a position of inflexible definition towards one of intelligent accord with forces animating the medical profession.

Urging on this drifting are very antagonistic elements. Physicians of the purest motives and highest character coöperate with those of selfish character and despicable motives. Promoting this drifting are state university medical schools, state medical examining boards, state and local boards of health, specialists, physicians, avaricious for fame, power or wealth, irrespective of the means by which they may attain their ends, and physicians jealous of professional honor and unselfishly serving humanity.

All these however are but instruments of far larger forces, which form a part of the development of the medical profession as a portion of the nineteenth century civilization. Of these we note briefly the following. First—The intellectual atmosphere of the century has become softer, as seen in the diminishing asperity in religious, social, scientific, political and

medical circles. Quite generally, we are learning that our opponents may be gentlemen, scholars, and valuable citizens, while vigorously opposing our individual beliefs and practices. Significant of the quality of this atmosphere was the meeting at Chicago of the representatives of all religions, and their discussing, under one roof, each others religious tenets. This atmosphere of free thought and untrammeled practice has stimulated men to expend their energies, without diversion, in the investigation of new fields or enriching old ones; to develop good rather than destroy evil; to prevent infection more than to cure the infected; to establish the conditions needful to produce level-headed physicians, rather than fight sectarian titles.

Second—With the advancing century humanity has acquired a larger faith in the ability of truth to look after its own interests, if only each individual did his own life-work in the most perfect manner. Hence, physicians have been disposed to give plenty of rope to the offenders of truth, in the belief that thus they will best dispose of themselves after the classical method of Judas Iscariot.

Third—The rapid incubation of physicians, by emigration of the products of the doctor factories of other countries, (an importation which pays no government duty), and by the swarms yearly graduating from the medical schools of the United States, has swelled our ranks to quite uncomfortable proportions. The situation is still farther aggravated by the fact that vast numbers of patients, which naturally should contribute to the support of physicians, are largely absorbed by hospitals, ambulances, dispensaries, contract physicians, railway physicians, accident insurance companies, medical college clinics, and numerous private institutions supported by shrewd advertising. This crowding compels each physician to cultivate his field to the fullest degree possible. He is compelled to know all about the sectarians as well as the physicians of his field. This close contact has proved that some sectarians are better educated, more gentlemanly and honorable than some regulars. This personal knowledge renders it possible for him to coöperate with the sectarians in the management of cases in which they have a mutual interest and profit. Except for the crowding, this knowledge would have been difficult of attainment; now it leads him to believe that professional character and ability are of higher importance than a sectarian name, and so powerfully drifts him away from the written law of consultations.

Fourth—Experience has shown that the fighting of a name, as that of a sectarian, is unprofitable to the fighter and the medical profession. Here, as elsewhere, "The blood of the martyrs is the seed of the church." Persecution of sectarians, under their official designation, but increases their prosperity and discredits the medical profession. The profession is drifting to the practice of ignoring the special name and of looking after qualifications for doing creditable work, of persuading individuals to abandon untenable errors in theory or practice, or better still, of so training medical students that they will avoid "isms" and "pathies," and intelligently enter upon their relations with active physicians.

Conclusions.—1. In the matter of consultations the medical profession is drifting from the law written in 1847 to the unwritten law inherent in the medical profession since the first doctor entered upon his work—far anterior to any historic record.

2. This drifting was inaugurated and is continued by forces and agencies which have made the nineteenth century the most remarkable in history—individual men or institutions have merely served as instruments for the operation of these forces and agencies.

3. There need be no anxiety concerning this drifting. The medical profession will always remain anchored to its fundamental nature of a competent honorable brotherhood. The changes sought are merely the substitution of a thing of universal application for a sectarian name of limited scope. It is sought to exclude from fellowship all who are incompetent or disreputable, whether they have or have not a sectarian name. The final attainment of this drifting will mark a far higher standard of professional life, and a truer exemplification of individual liberty.

4. It is believed that we are drifting towards the practical adoption of the following: "Every physician shall be deemed eligible for professional consultation who has shown that he has such pre-

liminary training as enabled him to comprehend the study of medicine; has fully mastered the elements of medical science and art; has complied with existing laws respecting physicians in the state of his residence; and who has maintained an honorable reputation. Of these qualifications the physicians of his locality shall be the final judges. If those who know him best endorse him, then shall he be freely admitted to membership in all medical organizations and be eligible for consultations."

5. If the profession fails to agree upon a statement in substance like the preceding, the logic of events points to a rejection of the entire written law of 1847, and a return to the unwritten law of previous centuries—the one now holding sway in all countries except the United States.

OSTEO-LIPO-CHONDROMA OF THE UPPER END OF THE HUMERUS; RESECTION OF HUMERUS.*

THOMAS R. NEILSON, M. D., PHILADELPHIA, PA.

The case is that of a young man who suffered from a tumor involving the head and upper end of the shaft of the right humerus. I saw him first in the early part of last February. His history was as follows: J. T. P., twenty-one years of age, worked on a farm until two years ago, when he learned the trade of electrical construction, in which his work has been light. Family history good; no history of tumors among relatives. In June, 1893, his attention was called by a fellow-workman, who saw him stripped, to an enlargement of the humerus the size of a pigeon's egg. One year later it had slowly grown to twice that size. Afterward it grew more rapidly, and in November, 1894, it began to cause inconvenience by its size—limiting the motions of the joint, and giving rise to a sensation of numbness occupying the back of the arm as far down as the elbow; there was also loss of sensation in the fingers, and he noticed some diminution of power in the hand, especially in using the hammer. At no time was there any pain in the growth. There was no history of injury to the shoulder.

Upon examination I found the upper end of the humerus markedly enlarged, the growth being hard and immovable and having an irregular surface, the larger portion of it projecting inward toward the axilla, and preventing complete adduction of the arm. From the history, the slowness of the growth, the absence of pain, the irregularity of the surface, and the uniform density of the mass, I believed the tumor to be an enchondroma, and felt that resection was to be advised. In this opinion Prof. Ashhurst, who kindly examined the patient for me, concurred.

The patient was admitted to the Episcopal Hospital on February 7, 1895. The measurements of the right shoulder as compared with the opposite side were as follows: Around the most prominent part of the head of the bone, just below the acromion (arm adducted), right, 18 inches; left, 15 inches; two inches below the acromion (arm adducted) the circumference of the right shoulder was 14¾ inches, and of the left 12 inches.

Operation. On February 13, with the assistance of my colleagues, Drs. Harte and H. C. Deaver, I resected the growth by the deltoid flap operation. Starting my incision at the tip of the coracoid process, I carried it downward along the groove between the deltoid and pectoralis major, and then across the arm to the outer side at the level of the insertion of the deltoid. I next dissected back the skin and superficial fascia about an inch for the whole extent of the incision, and then divided the deltoid transversely about two inches above its insertion. The flap being turned back, the tendon of the long head of the biceps was freed from its groove and held to one side, the capsule of the joint opened,

*Surgeon to the Episcopal Hospital and to St. Christopher's Hospital for Children.

the insertions of the supra and infra-spinatus and teres minor severed, and the attachments of the sub-scapularis divided. The growth was so large thas it was found impossible to complete disarticulation until the attachments of the coraco-brachialis and of the pectoralis major were also divided. This being accomplished I sawed through the humerus just above the insertion of the deltoid. After making the section I noticed a suspicious spot of degenerated tissue remaining, and, pushing back the periosteum with the insertion of deltoid, I cut off another inch of the bone.

Throughout the operation there was no arterial hemorrhage of moment, only a few muscular branches requiring ligature; but the cephalic vein was, unfortunately, slightly torn at the beginning of the operation while pushing it aside in the groove between the deltoid and the pectoralis major, and again later when delivering the growth. I tied it below the tear, and again some distance further up, and resected the intervening segment—about five inches in length.

This being done, the wound was flushed with normal salt solution, and the deltoid united with several quilted sutures of kangaroo-tendon. A large rubber drainage tube was inserted, and the wound closed with silk sutures. A bichloride-gauze dressing was applied and the arm bandaged to the side, a large axillary pad supporting it.

The patient did remarkably well and the wound healed kindly.

There was no noteworthy occurrence until the eighteenth day, when it was found that, at a point about the centre of the wound just over the anterior axillary fold, the union had broken down, and there was a slight purulent discharge. The cause of this was found to be one of the kangaroo-tendon sutures, which was working its way out. Four days later another of these sutures was discharged from the little sinus, and again in five days a third one. The sinus then healed firmly.

On March 30th the patient was discharged from the hospital. At that time the contraction of the deltoid showed that it had united firmly, in spite of the fact that three of the kangaroo sutures had cut their way out, owing to imperfect sterilization.

The patient has now very good motion of the arm, and he tells me that he has returned to his former work at electrical construction. The specimen shows the tumor to be nearly twice the size of the fist, and to have grown largely toward the inner aspect of the bone. A section of the growth was examined by Dr. Joseph McFarland, pathologist to the Hospital, who reported the microscopical diagnosis to be osteo-lipo-chondroma.

DEFORMITIES FOLLOWING FRACTURES OF THE SHAFTS OF BONES, WITH OBSERVATIONS ON THE TREATMENT.*

THOMAS H. MANLEY, M.D., NEW YORK.

Serious fractures of the shafts of long bones constitute a considerable proportion of all the major traumatisms of the body. Many are attended with danger to the vitality of the limb by such destruction as may lead to ultimate gangrene; while a considerable number leave various grades of deformity, with or without shortening.

Deformity after fracture is dependent on various causes, some of which are preventable and others are not. These have reference to local conditions, the quality of the fracture, the age of the patient, the state of the general health and the treatment instituted.

Fractures which extend into a joint or involve an articular diastasis, or subluxations with an extensive laceration of ligament and tendon, are liable to unite with an excessive callous formation and more or less distortion of contour.

In one class of fracture-deformities but little functional impairment or diminished strength is experienced, while in fracture

*Author's abstract of paper read before the American Medical Association, May, 1895.

dislocations ultimate impediment in action is the marked characteristic. This it notably the case in the typical Potts' at the ankle joint, Colles' at the wrist and elbow-joint fractures where the bone gives way through the condyles of the humerus. Under many circumstances we are obliged to content ourselves with endeavoring to save the damaged limb, quite irrespective of the quality of deformity.

Preventable causes of deformity are neglect, or want of skill in treatment. In all simple uncomplicated fractures the tendency of the fragments is to fall into place and unite without resulting in displacement; but in certain varieties in order to prevent distortion we must anticipate those conditions which lead to it. This is only possible through a familiarity with the various phases of osseous regeneration, which can only be acquired by a knowledge of the correct principle of fracture-therapy, with ample opportunity to observe and treat a large number of cases.

Theoretically the successful treatment of a fracture is the essence of simplicity; for, mechanically, there is no displacement which we cannot overcome and no shortening that may not be obviated. But when we bear in mind that we are dealing with living structures which, after injury possessing but a feeble vitality, are not prone to bear pressure well; that the tolerance of the tissues or structures to manipulation widely varies; and that commonly we have to deal with severe internal injuries simultaneously, the problem is not so simple.

In strumous and rickety patients union may be greatly delayed or be very imperfect. In others again it may fail for weeks and then for some unknown reason ossification will suddenly set in and consolidate the fragments in a few days. Where there has been but slight damage to the overlying parts in young subjects, and perfect reposition is possible, complete consolidation may occur in one week. Therefore if we relax our vigilance and fail to provide proper support at the right time, a deflection or displacement is quite certain to result. This is most liable to occur when plaster-of-Paris is employed, because the gypsum dressing fails to hold the fragments steady after the swelling of the limb subsides; nor can it be well removed without jarring the limb. It so hermetically conceals everything that nothing short of its entire removal will enable us to frequently examine the limb during the course of treatment. In fractures of the femur the patient's health, failing under compulsory confinement to bed, may so suffer that we are obliged to raise them and relax their supports before final consolidation, when by so doing the tendency to overriding or bowing of the fragments will be greatly enhanced.

SURGICAL MEASURES FOR THE RELIEF OF DEFORMITIES AFTER FRACTURE.

As it is true that deformity cannot be prevented in a considerable number of fractures, it is equally so that but comparatively few can be overcome after union by surgical measures, except in occasional cases at the elbow in youths. For those fractures extending into joints little or nothing can be promised by surgical operation in the way of overcoming a deformity, though for the impediment in function, by anchylosis or wasting, very much may be accomplished.

Surgical operations which may be utilized to overcome this class of deformities may be technically divided into: 1, Osteorection; 2, osteoclasis; 3, osteotomy; 4, osteectomy.

The first two may be utilized safely and with advantage in a large number of cases, while the two latter are not to be employed unless the extent of deformity is great, or is a source of constant pain, or seriously impairs the limb. At any stage of fracture treatment before ossification is complete we may employ osteorection—a bending of the bone—with great advantage. In certain femoral cases with marked bowing and shortening, utilized at the proper time it is marvelous how we may by a simple bending of the shaft into line, at once restore symmetry and normal length.

Osteoclasis, or re-fracture, succeeds well in the smaller bones of growing subjects, but with the large bone shafts, as the femur, while we may succeed in effecting a re-fracture, it may not be at the right point to be of any benefit and, besides, in applying the necessary force we may do serious damage to the large blood-trunks or to nerves which are in near contact. The period at which osteoclasis can be utilized with advantage and safety is in the transitional stage from the

endo-chondral to ossific development while the callous is yet succulent and pliant. After the consolidation is complete and the hardening stages are past the most certain and reliable success of fracturing a bone over the site of a recent fracture is to resort to osteotomy.

This, it should be remembered, in this class of cases is a severe procedure which is by no means uniformly successful in its results. In some the extent of reaction, local and general, is very great. In the femoral deformities of the adult the extreme intolerance of the medullary substance to mechanical interference renders it an operation of great uncertainty and always full of peril. It will do better in the bones of the leg and upper extremity. The most rigorous asepsis must always be observed, and we should have a care that no irritating chemicals or hot water come in contact with the osseous elements.

Oste-ectomy, or excision of the bone-substance, is rarely required in deformities of the shafts after breaks; but in three difficult cases of clavicular fracture, with resulting hyperostosis and displacement attended with arm paralysis from pressure of the callous on the brachial plexus, it has served me a most useful purpose. Like osteotomy, it is a severe undertaking which should not be resorted to unless its indications are clear and the environment of our patient is such as will warrant the risk which it always entails.

To recapitulate, it may be said that in this class of surgical cases, as in many others, "an ounce of prevention is worth a pound of cure"; that the main object is to endeavor, if possible, in all cases to obviate deformity in the primary stages of treatment; and when one has any doubts as to his own ability to properly manage a complicated case, it will tend to safeguard his own reputation and will be in the interests of his patient if he summons an experienced surgeon. When there is reasonable ground for believing that a marked deviation is setting in, active, early interference will in many cases readily correct it, while if permitted to remain until solidification and eburnation are advanced, nothing short of a major operation, quite on a par with an amputation, can even give us hope for restoration of contour and full functional action in the now distorted limb.

REMARKS UPON TREPHINING THE CRANIUM.

JOHN ASHHURST, JR., M.D.,* PHILADELPHIA, PA.

I find that I have performed the operation of trephining the skull forty-one times, not including those cases in which I have merely opened the frontal sinuses, nor those in which I have removed bone-fragments without using the trephine. Of these forty-one cases twenty ended in recovery and twenty-one in death, showing a mortality of little more than 50 per cent. In many instances I have refrained from interference when other surgeons would have operated, so that my cases have been of an unfavorable type, and the mortality has no doubt been higher than if I had operated more indiscriminately.

The details of these cases are as follows: Twenty-four were primary operations for compound fracture, with eleven recoveries and thirteen deaths; two were operations during the intermediate period, both successful; and three were secondary operations, with one recovery and two deaths, both in cases of abscess.

As far as it goes this analysis confirms what has so often been pointed out, that there is not so much urgency in operating as upon compound fractures of the extremities. In the latter, the sooner the operation is done, if the patient is able to bear it, the better. This has long been the rule in military surgery when amputation is required, and some years ago I collected extensive statistics from civil practice which showed that the same rule of procedure applied there. But this is not so

* Barton Professor of Surgery and Professor of Clinical Surgery in the University of Pennsylvania, Surgeon to the Pennsylvania Hospital, etc.

in compound fractures of the skull, and the proportion of recoveries is larger in delayed cases than when the operation is done immediately, as is well shown by Bluhm's statistics. At the same time, in a bad case, where an operation is evidently necessary, I do not advise delay; but early trephining is not so imperative as is early amputation for compound fractures of the long bones. Trephining for suppuration, occuring as the result of injury, is usually fatal.

In three cases I have operated for syphilitic disease, with two deaths and one recovery. In the latter case, besides evidence of syphilitic brain disease, there were painful nodes on the skull, and I operated by dividing the nodes with a Hey's saw, and then made a single opening with the trephine, so as to relieve the intracranial tension. The patient was much benefited for a time, and left the hospital relieved, though not cured. The fatal cases were in patients suffering from syphilis of long standing, with necrosis and intracranial suppuration.

I have been induced to trephine in three cases of epilepsy, all the patients recovering from the operation. One, an epileptic with suicidal tendencies, came under my care at the University Hospital in October, 1886. After the operation the patient was much benefited as long as he remained under observation. In the other two there was no evident improvement, though both did well as regarded the operation. In a case of melancholia following an old fracture of the skull, trephining gave no relief, and of two cases in which I operated for convulsions, etc., following old injury, one terminated fatally, while no permanent gain resulted in the other.

I have operated unsuccessfully upon three patients for the cerebral complications resulting from disease of the middle ear. Statistics show that many lives have been saved by trephining under these circumstances, but in my own cases, though the abscesses have been reached and evacuated, the patients have died.

Although I have thus operated in twenty-one fatal cases by trephining, in only one case did the operation seem to have been responsible for the patient's death. This case was that of a child with a depressed fracture over the lateral sinus. On removing the depressed bone profuse hemorrhage occurred, and the patient died in consequence. I had not then learned the futility of attempting to check bleeding from the brain sinuses, except by prompt plugging. I have since had four cases in which the longitudinal sinus was opened, and in two of them the patients recovered. In a third, bleeding was readily controlled by pressure, but ultimately death followed; while in the fourth a clot had formed in the sinus, giving time to apply a lateral suture to the divided vessel. This case was an interesting one; it was that of a boy who had been injured by a nitro-glycerin explosion, a piece of the metal being found lodged in the longitudinal sinus, causing a clot as mentioned.

As regards the locality of the injury, I find that of fractures of the frontal bone, omitting those simply involving the frontal sinuses, there were five, with four recoveries and one death. These figures do not confirm the general impression that there is special danger in fractures of the frontal bone. Indeed, much more depends upon the amount of injury to the brain than upon the place of the fracture. In one case the indication for trephining was bleeding from the middle meningeal artery, and in that case the patient recovered. He was an athlete, who, while playing football came into violent collision with another player, sustaining a fissured fracture of the parietal bone. He was stunned at the time, but soon recovered consciousness; in the course of half an hour, however, convulsions came on, followed by coma. He was brought to the hospital, and I applied the trephine, evacuating a considerable quantity of clot; the patient made an uninterrupted recovery.

In cases where there is a marked depressed fracture of the skull, whether to leave it and wait for developments, or to proceed at once, I wish to be understood as saying that I would not push the argument from statistics, and that in cases in which the operation was clearly indicated I would operate at once; but that in cases where there was a doubt in the mind of the surgeon as to whether or not he should operate, a short delay would not be as injurious as it would be in the case of amputation. In cases of impacted fracture my practice has been, as a rule, not to interfere in the absence of symptoms. In cases where there is no opening into the cranial cavity and where there are no cere-

bral symptoms, I think the surgeon is justified in waiting for more definite indications. At the same time I find myself more inclined to operate than I was twenty years ago, on account of the greater safety afforded by modern methods of wound treatment.

I do not recall any case of discharge of brain-matter from the ear, but loss of brain-substance not infrequently occurs at the seat of fracture. With regard to the watery discharge from the ear I have often observed that as long as the discharge continues the patient may do well, but that if it suddenly stops the patient will probably become comatose and die in a few hours; the arrest of this flow seems to increase the pressure upon the brain. Old residents of the Pennsylvania Hospital will remember a case under the care of the late Professor Joseph Pancoast, in which there had been such a free discharge from the ear that it had been collected in a cup to be measured. The cup was found empty in the morning, and upon investigation it was learned that the night watchman had mistaken the fluid for medicine and had administered it to the patient, a tablespoonful every three hours, during the night.

With regard to fractures at the base of the skull, I have not seen any case which I thought trephining indicated. I think that an attempt should be made to prevent infection in these cases by cleansing the ears, and, as far as possible, the nasal and buccal cavities. After securing cleanliness I rely upon the use of calomel and Dover's powder, with hygienic treatment, rest in bed, cold to the head, laxative enemata, etc., and by these means recovery will be obtained in a considerable number of cases.

EXPERIENCES IN THE TREATMENT OF DIPHTHERIA.*

WILLIAM SHAW STEWART, A. M., M. D.,† PHILADELPHIA, PA.

In the limits of a ten-minute paper on *treatment* of diphtheria there is not time to enter into a differential diagnosis of the true and false or spurious and genuine. I will, therefore, trust that you will credit me with a knowledge of the various forms, conditions and characteristics of this disease after being in constant general practice for more than thirty-two years. It was my privilege, while a student of medicine, in 1861, to apply a treatment for this disease successfully—a remedy which has been, with me, most efficacious ever since.

At that time, diphtheria of a most virulent type was prevailing in Western Pennsylvania. The doctors were unable to combat it or arrest its progress. In a village near my home a child complained of sore throat, the family physician was not available, I was requested to see the child, a boy about two years old. The patches of membrane were plainly visible on both tonsils. The only remedy at hand was the Tinctura-ferri-chloridi; a swab, saturated in a solution of the iron, applied briskly over the tonsils dislodged the membrane. Courage was inspired by this result and the application was repeated several times daily until the child made a complete recovery. Another member of the same family took the disease, was subjected to the same treatment and recovered. I was then obliged to leave the locality to attend lectures in Philadelphia, but learned subsequently that a third case in the family succumbed to the disease; the family physician was summoned but failed to effect a cure. I was consequently impressed with the fortunate hit on so valuable a remedy.

Immediately after graduating from the Jefferson College, I went before the State Examining Board and was commissioned Assistant Surgeon in the Army of the Potomac. While in winter quarters I had abundant opportunity to study this disease

*Read before the Pennsylvania State Medical Society, Chambersburg, May, 1895.

† Professor Emeritus of Obstetrics and Clinical Gynecology in the Medico-Chirurgical College Philadelphia; Member of American Academy of Medicine; also American, State, Philadelphia County, Obstetrical and Medico Legal Medical Societies, etc. etc.

and was led to experiment with the application of the well known styptic which was among the army supplies, liquid persulphate of iron. It proved to be the "sine qua non," and your speaker realized he could truly exclaim "Eureka! Eureka!" After the close of the war, on engaging in general practice and joining the Philadelphia County Medical Society, I was persuaded that it would be an advantage to the profession and a relief to humanity to announce the success attending the new method of treatment. Accordingly I read a paper before the Society. In opening the discussion on the value of the new method, a prominent specialist, who was regarded as an authority on throat diseases, did not hesitate to annihilate the young doctor in his opening sentence, "I condemn the doctor's paper in toto." Such a squelching remark, followed by the assertion that the cases must have been spurious or his statements false, prevented any credence being given to the valuable discovery. I was practically left to pursue my course alone in the treatment of this dreadful disease.

It is now thirty-four years since I began this treatment and I am no less sanguine about the value of liq. ferri sub-sulphatis, and I can now state further that I have never in all these years lost an adult having an uncomplicated case of diphtheria, and only one where pneumonia was the complication and the patient really died from the effects of the latter. Can we expect better results from antitoxine? I must admit, with great regret, that the record is not so gratifying with children, although from comparison I find, even among them, this remedy is exceptionally successful.

The difficulty is in the application. To overcome this, in the families regularly under my care, I impress upon parents and nurses the importance of teaching young children to gargle, using plain water, thus preparing them for an emergency. It is imperative that the membrane should be cleaned from the throat as it re-forms, the swabbing must be not only carefully but thoroughly done. A busy practitioner can rarely find time to visit his patient more than twice a day, so co-operation on the part of parents, nurses and, if possible, the sufferer, greatly facilitates the end to be obtained. The true secret of the successful treatment of diphtheria is to keep the deposits cleaned off and thus prevent propagation—for in the development of the germ seems to lie the devitalizing element.

Internally, a saturated solution, potassium chlorate, in teaspoonful doses (equivalent to about 7 grains) given every two hours, in each dose two drops of the subsulphate of iron, if taken in the beginning, will often arrest the development of the disease, but if the patches have appeared, you dare not rely on internal medication alone, but should immediately resort to the gargle of Monsel's Solution in the proportion of a drachm to the ½ pint of cold or hot water, as is most agreeable to the patient. There is but one rule for the gargle. At each time the patient must not desist until by repeated persistent efforts every particle of the membrane is removed, and repetition every half hour or oftener is necessary. If the patient cannot gargle, there should be the careful application of a swab, saturated in diluted sub-sulphate of iron, making as little abrasion of the mucous membrane as possible, repeated as frequently as needed to keep the disease under control, not permitting the patient to sleep more than two hours at a time during the night or day.

My experience warrants the assertion that faithful, persistent use of this remedy in the manner stated will carry the patient over the crisis of the most malignant attack in from four to five days, provided, the patient comes under your care in the early stages of the disease.

Causes.—This being a practical rather than a scientific paper on this subject, permit me to mention some of the ever possible sources of diphtheria. Putridity arising from decaying vegetable or animal matter in the cellar, house or yard, the decomposing of animal matter, such as a mouse or rat, under the floor or in a heater, as experience has proved, also the unflushed sewer, containing debris from street, public house or private dwelling.

Communicability.—Diphtheria, if neglected in one case, will soon become a nidus from which every member of a household may be infected, but if promptly attended, and the membrane kept cleaned off, there is little or no danger of contagion. In my experience, on more than one occasion, I have been able to determine the nature of the disease before speaking to the patient I have been sum-

moned to see, by the characteristic odor. I remember, during the Centennial being called to see a man who was ill; he had brought his bride from Jefferson County on their wedding trip, to the Exhibition. Stating the trouble to be diphtheria, when I entered the room, shrieks of despair from the bride and demonstrations of grief warned against any further declarations. Being assured that her husband would be well in about five days, she became calm and told me that in their county this disease was an epidemic and almost every case proved fatal. The disease yielded to treatment and the last visit was made on the fifth day. Because of the prompt and successful results in this case an urgent request came through the mail for the name of the medicine which had been so effectual. I need hardly add, it gave me great pleasure to respond, and to give specific directions how to use the remedy.

In this connection, as confirmatory proof of the value of the medicine, I will refer you to a clinical report published in the MEDICAL AND SURGICAL REPORTER, of Phiiladelphia, May 12, 1894, which was quoted from the Clinical Society of Louisville. This is the language of Dr. P. Gunteman:

"I want to give my testimony to a drug that I have used for the last two years, exclusively in the treatment of diphtheria, i.e., the local application of the subsulphate of iron, since the report of some physicians from Bowling Green, Kentucky, whose statement was to the effect that they had treated 250 cases by this method with only one death. I had treated 18 cases and no death." In the discussion which followed, Dr. J. W. Irwin said, "I listened with a great deal of interest to the remarks made by Dr. Gunteman concerning the use of Monsel's Solution, locally, in the treatment of diphtheria, etc., and I had just read an article written by somebody in Pennsylvania, who wrote of the wonderful effect of this remedy, and like every new thing it was lauded to the skies, etc."

The "somebody in Pennsylvania," who lauded the remedy then, is still as sanguine as ever that he made no mistake in proclaiming the virtues of sub-sulphate of iron as a local treatment of diphtheria. Although I have expressed my confidence in the local application of liquor ferri subsulphatis as superior to any other remedy, yet do not understand that I would have you depend entirely upon this powerful styptic. I have at times been obliged to use a blunt curette to scrape off the membrane, afterwards applying cosmoline, sulphur and soothing unguents. In the post-nasal development of the disease, I do not hesitate to pass an aluminum probe through both nostrils, the probe curved to suit, wrapped with absorbent cotton and saturated with whatever the conditions suggest in order to destroy the germs of the disease, which I have frequently found passing along the mucous track and the channels leading from the openings of the eyes and ears. As a final word I would urge upon you not to undertake to treat a case of diphtheria unless you do your work fearlessly, heroically, attentively and thoroughly, and you will not fail in your results.

THE PROTRACTED FEVERS OF WEST TENNESSEE.*

T. R. MOSS, M. D., DYERSBURG, TENN.

In West Tennessee we have a form of fever which, I think, has been more prevalent during the past twenty years then at any time prior to this period. It generally continues about four weeks, but frequently longer when complicated. There has been much said and written concerning a proper name for it but it has never been settled beyond controversy as in other sections of the country is typhoid fever, scarlet fever, or variola, etc., the identity of which no one calls in question. I cannot say if it is clinically the same fever as is met with in other states of similar climatic influence; but I can say, however, that the descriptions which I see from time to time do not correspond entirely with those cases I am accustomed to deal with. That the name typho-malarial as given to a certain fever by Dr. Joseph J. Woodward in 1863, still has its advocates, no better proof can be given than the following, from the pen of the

*Read before the Tennessee State Medical Society, April, 1895.

worthy man, now deceased, whose name appears as President of the Tennessee State Medical Society: "Is Typho-Malarial Fever a Disease Per Se?"

Summarizing I have reached the following conclusions: *First*—The fever we have in this part of the country every autumn is not an acute infectious disease as is typhoid fever. *Second*—Typho is probably due to pathological changes, the result of long continued exposure to malarial influences or theoretically to one or more of the six or eight parasites found in the blood of patients suffering from malarial fevers. To some of these quinine is said to be nontoxic. Typhoid is due to a specific poison. *Third*—The incubation and duration of typho are much less fixed than that in typhoid. *Fourth*—The temperature range of typho is less uniform and regular than that of typhoid. *Fifth*—Diarrhœa is often wanting in typho and rarely absent after the first week in typhoid. *Sixth*—The typho tongue never evidences the gravity of disease that the typhoid tongue does. *Seventh*—I have never seen sordes on the teeth, gums, lips and in the roof of the mouth in typho, but have frequently in typhoid. *Eighth*—I have never discovered the typhoid eruption on the persons of typho-malarial patients. It occurs in eighty-eight per cent of typhoid patients. *Ninth*—Bronchial and pulmonary symptoms are rare in typho, common in typhoid. *Tenth*—The nervous symptoms in typho are absolutely wanting in comparison to their constancy and gravity in typhoid. *Eleventh*—The great pathology of typhoid fever as discovered by the symptoms, existing in a much smaller percentage of cases in typho than in typhoid. *Twelfth*—By the intestinal dejecta typhoid fever is disseminated, but there is no evidence that this is true of the dejecta of typho. Finally, even if the so-called typho-malaria fever of this country is really typhoid fever, the abandonment of the name typho would, in the present status of our knowledge, be premature. Thus it is to be seen, gentlemen, that there are still those who cling to the name typho-malarial, notwithstanding much has been said and written in favor of calling the disease typhoid fever. This fever is no respecter of persons except that those at the extremes of life are probably not so susceptible to its influence.

The onset of an attack occasionally appears to be sudden, but usually it is gradual.

In nearly all cases, if sought for, a history will be elicited of general malaise, loss of appetite, slight fever, a furred coat on the tongue, constipation and headache extending back for one or two weeks. At his first visit the physician usually finds his patient with a temperature from 101½° to 104° or higher, and, by the way, the themometric range at the first visit is quite often a fair index as to the gravity of the case. The tongue is generally red at the tip and edges, the triangular red spot at the tip being the most important sign connected with that organ in the beginning when it is necessary to give an opinion as to the probable duration of the illness.

I regard the red tip and edges of more importance as a diagnostic sign than the pale flabby tongue, on the edges of which the teeth's print can be seen. I frequently meet with this character of tongue, but I do not think it has any great significance in so far as pertains to this special form of fever. The pulse is rather peculiar, in the fact that quite often for a number of days it ranges from seventy-five to ninety, while the temperature is 102½° to 104°. I cannot account for this and would like to know if the experience of others corroborates my own. As the disease continues and the heart's action grows weaker, the pulse increases, buf the temperature curve so characteristic of typhoid fever in its typical form is entirely wanting, and quite often the fever is as high, or higher, at the first visit as at any time thereafter. According to the rule which most fevers obey the temperature is lower in the forenoon than in the afternoon. A temperature of 103½° or 104° in the morning is quite significant, and prompt measures should be instituted to reduce it, else as night approaches it will get very high, probably reaching 105°, or higher.

In some instances the disease is so mild that patients will not remain in bed, but drag themselves around for several weeks with a temperature of 99½° or 100°. In a case of ordinary severity properly treated the temperature ranges from about 102° in the forenoon to 104° in the afternoon, and quite often in addition to the afternoon rise there will be another at some time

during the night, usually between 12 and 4 o'clock. There may be others at irregular intervals but most usually only one or two, coming as stated. These exacerbations are frequently attended with rigors, the patient calls for more to cover him and thinks he is about to freeze when the thermometer under the tongue registers 104½° or 105°, and when in this condition patients will usually protest most vigorously against cold water to the body, and usually a warm water bath will be consented to. In most cases the bowels are not troublesome, but generally laxatives have to be administered to make them act as often as is necessary to the comfort and well-being of the patient. It is often the case that diarrhœa is present and requires something to control it, which usually is not hard to do.

When there is diarrhœa the stools are generally thin and quite offensive in odor, their odor and color indicating an absence of bile.

Intestinal hemorrhage sometimes occurs, and in the cases coming under my observation was rapidly fatal.

There is frequently tenderness over the abdomen and in one case under my care—a little girl 13 years of age—the pain in the iliac region was so marked for several days that I began to suspect appendiciitis.

Tympanites is rarely present to a marked extent, but when it is so, becomes a most formidable symptom. Sordies does not occur except in grave cases attended with hebetude or a low form of delirium. I have never seen the rose colored spots which are of such diagnostic importance in typical typhoid fever, but possibly I have not made close enough search for them in every case.

Neuralgic pains in the chest or back is present in nearly every case at the beginning. As a rule they disappear after three or four days and do not return. Head-ache is frequently present, but usually not marked except when the temperature is high. Delirium is usually absent, but in severe cases where it comes on late in the progress of the disease indicates a gloomy outlook for the patient.

Epistaxis was present at the beginning in the majority of cases which I saw.

Vomiting frequently occurs during the first few days after which it usually subsides. Exceptionally, however, it persists throughout the entire attack, materially interfering with the administration of remedial agents. I just now call to memory a case which continued for twelve weeks which could retain absolutely nothing but fever powders and buttermilk. The patient finally died from hypostatic congestion of the lungs, and heart failure. Bathing even could not be satisfactorily carried on in this instance.

The urine is frequently scant and highly colored, but usually the kidneys are not very troublesome. Venous thrombosis occasionally occurs and when present adds to the gravity as well as duration of the disease. A case is referred to under the head of treatment in which the fever continued 105 days. Venous thrombosis and probably phlebitis occuring first in the left, and afterwards in the right leg.

The history of swampy, timbered countries, when new especially, is that of acute malaria manifesting itself in chills and transient fevers, that as they grow older and the population increases, this gradually gives way and typhoid fever makes its appearance. A quarter of a century ago, chills and the fever which follows them were common, now they are very uncommon. Simple remittent or billious fever lasting from 3 to 10 or 12 days was also quite common, now it is uncommon.

The causes which produce malaria have not all disappeared from the country, but a change has come over the character of sickness, and the question arises, what have we now, and what the cause which produces the change?

In the beginning of my practice calls were frequent for prescriptions for chronic chills; now I don't have six a year. Why this difference?

(1st.) We now have in typhoid fever one which is self limited.

(2.) We now have a form of fever which no known medication will check, but which runs its course in spite of all the ingenuity of man. Typhoid acts similar.

(3rd.) Frequently when it enters a household, one, two, or a half dozen others follow. This is true of typhoid fever.

(4th.) Diarrhœa and intestinal hemorrhage are symptoms which make their appearance in this disease. These symptoms belong to typhoid fever.

(5th.) Venous thrombosis occasionally occurs as a complication with this fever.

(6th.) Epistaxis is present in the majority of cases at the beginning. It is a

symptom of diagnostic importance in typhoid fever.

With the foregoing train of symptoms which I have given as faithfully as I know them, after an experience of fourteen years practice in West Tennessee, and recognizing that some valued sign of typhoid in its typical form are wanting, I desire to ask of this intelligent body of medical gentlemen, shall we denominate this fever typho-malarial or a typical typhoid fever?

Treatment:—I generally begin treatment with an effective dose of calomel with soda. Quite often it is necessary to repeat this two or three times in the course of the disease. Proper treatment and good nursing will succeed in curing a majority of cases.

The nurse should be instructed in the use of the thermometer, and given to understand how to keep a regular record of the case, so that when the physician makes his visits he can get a more reliable history as to the progress of the case.

Patients should not be allowed to lie on feather-beds, mattresses are far better. In one instance an air bed was used, but having been covered with some kind of an oily preparation, though it was dry, the osmosis from the skin towards the bed was so great that in a short while the gown would be perfectly wet and water standing in the depression beneath the body. On this account it had to be abandoned though it was exceedingly comfortable and the patient was very fond of it. It is difficult to use a bed-pan on a bed of any kind. Patient should maintain the horizontal position during the entire attack and when one is stubborn and will not do so, he always suffers in consequence, unless it be a very mild case. Good milk, according to my observation, is the most suitable diet. Sweet milk is more nourishing but most patients prefer buttermilk, and will take it with avidity from the beginning to the ending of a four or five weeks spell. Occasionally persons are met with who can not be induced to take milk under any circumstances, when soft eggs or milk toast, etc. may be cautiously given. In giving buttermilk it should always be perfectly fresh. It is sometime ssurprising how well buttermilk will nourish a patient with this fever. The stomach and bowels are usually free from gas and the restlessness and nervousness are less with a pure fresh milk diet than any I know of.

It is highly important to keep the stomach quiet throughout an attack, because if rebellious it materially interferes with the administration of proper remedies, and a simple case is resolved into one of gravity. In order to do this studiously avoid the use of opium and do not use it if possible to get around it. Opium checks the secretion from the liver, constipates the bowels, and causes them to fill with gas. In cases attended with laxness of the bowels or diarrhœa, opium sometimes renders good service. I use phenacetine to a very limited extent, and rarely give it at all unless the temperature is above 102½°, and then in doses just sufficient to produce a slight moisture of the skin, intending that it shall only act as adjuvant to a more desirable method of reducing fever. Free bathing is absolutely indispensable to a successful issue in the treatment of this fever, except in very mild cases. In private practice however, it is entirely impracticable to follow the Brandt method of immersing the body in cold water, as it requires a number of assistants which are seldom to be had, besides very few patients are provided with bath tubs and still fewer able to buy them.

My custom is to have the water applied to the body as the patients lies in bed; it is best applied by means of soft cloths, bathing constantly for twenty or thirty minutes. Cold or warm water may be used according to the wishes of the patient. Cold water will reduce fever quicker, and when agreeable I prefer it; but with a tendency to cold hands and feet and other evidences of internal engorgement warm water is, I think, safer. When water is applied to the patient one nurse can for weeks frequently give all attention necessary. I have a patient who is now recovering from an attack in which the fever lasted 105 days, and during the whole of this time he was nursed and bathed almost exclusively by his wife. A towel wrung out of cold water and applied to the bowels, covered by a dry one invariably gives quite a degree of comfort, besides it helps to lower temperature and has a good influence in keeping down tympanites.

Of all internal remedies for the reduction of temperature in the protracted fevers of West Tennessee none are to be

compared for efficiency and safety with quinine. The sulphate or bi-sulphate may be used, but unless contraindicated by an irritable stomach or nervous system the sulphate is preferable.

Some practitioners treat this fever with but little if any quinine after the first 3 or 4 days, and mild cases with a low grade of fever require very little, but my observation during fourteen years experience in the treatment of this fever with and without quinine, has convinced me that cases with a high grade of fever treated by antipyretic doses of quinine and free bathing do better than treated by bathing without the quinine. In cases where quinine is required for its antipyretic influence less than 40 or 60 grains in the 24 hours does very little good, and quite often this amount will have to be increased to meet the requirements. Care should be used to avoid depression and sometimes stimulants and nerve sedatives are necessary in order to its successful administration. Usually, however, after it has been given 2 or 3 days the system becomes tolerant of its presence and no more trouble is experienced from it.

The object in its administration should be mainly that of an antipyretic, and inasmuch as a temperature of 101° or 102° does not exhaust rapidly, only enough should be given aided by the bath to keep the fever at about this point. As a rule this can be done without "fever powders." Occasionally the stomach rebels at quinine, and an amount sufficient to reduce the fever can not be tolerated, the nervous system becomes disturbed and through this violent persisting vomiting is induced. I instances of this kind if possible the quinine should be lessened or suspended for awhile, but if not considered safe to do so, then chloral hydrate and potassium bromide suspended in mucilage of Acacia should be given per rectum; but if both the stomach and the rectum are irritable, hypodermic injections of morphine and atropia sometimes act nicely; very often, however, the after effects of the morphine is worse than the quinine.

I have never been very successful in giving quinine by suppository, and never but in one case was I cruel enough to give it continuously by hypodermic injection. Possibly it might be said do not give it at all under such circumstances. It is needless to give such advice as it cannot be given to any advantage, but such cases frequently terminate unpleasantly because one of the best friends of both the patient and doctor has failed, and the chances are that ordinary bathing will not control the fever which is rapidly consuming the body.

If some doctor would invent a contrivance by which private families could immerse their sick fever members in water as often as needed with a limited amount of assistance, he would confer an inestimable blessing on the human race. The wet sheet is about as inconvenient as immersion in water.

Very often a case will be pursuing a satisfactory course when severe rigors, followed by immense elevations of temperature, will occur. It is in just such cases that quinine, if given with a liberal hand, will do a most noble work. Having seen this state of things yield so nicely to quinine and free bathing, and having seen bathing alone so utterly fail, is it any wonder I should consider quinine my friend under such circumstances? Quinine should be given with three objects in view: 1, Reduction of temperature; 2, equalization of circulation; 3, neutralization of any malaria which may arise from time to time on children. It is best to keep a close watch for amblyopia, inasmuch as some are very susceptible to the action of quinine. Amblyopia is not as transient as some authors would seem to think. I know two cases, one of nearly six and one of nearly two years duration, in which the field of vision is very much contracted. Guaiacol has been vaunted as an efficient agent in reducing the temperature in typhoid fever.

An article in *Medical News* of January 19, 1895, from H. G. McCormick, M. D., of Williamsport, Pa., concludes as follows: "I have thoroughly tried the bath and cold packs and I know they have proved very efficacious in many cases, but with my experience with Guaiacol I have no desire to return to either of them." I can not speak from experience. The bowels need attention and if constipated should by mild measures be induced to move every 24 or 36 hours. If diarrhœa is present and the stools offensive opium, bismuth subnit, and salol should be given to check the frequent actions and destroy the odor. Intestinal antiseptics are always indicated, whether there be diarrhœa

or constipation; and I know of no better mixture than carbolic acid. Co. tr. iodine and Fowler's solution, in which is combined both antiseptic and anti-malarial agents. Turpentine suspended in cinnamon water and powd. acacia is a very effective mixture and but little, if at all inferior to the carbolic solution. I have used sulpho-carbolate in two cases only, they did well. I think favorably of the chlorinatep quinine solution of Yeo but have not used it. It is composed of potassium chlorate made strong by hydrochloric acid and water, to which quinine is added and syrup of orange peel to flavor. If this is not too bitter, I think it is worth trying. Dryness of the mouth needs attention; a solution of chloride of sodium is a good wash, and glycerine will help remove the dryness. Exhausting sweats frequently occur late in the disease, for this tr. digitalis with atrophia or tr. belladonna answers a good purpose. Strychnia, alcohol and ammonia have their places in the treatment, and under certain conditions can not be dispensed with; but I will not take up time to dwell on them. Hypnotics are frequently required to produce sleep, and for this I am partial to Wampolea hypro-bromic compound. Venous thrombosis, with its results, requires soothing applications with anodynes to relieve the pain of the accompanying phlebitis, careful handling, and later, electricity and bandaging. I have a case of this kind under treatment at present. After the cessation of fever, prudence in diet, tonics and the avoidance of severe muscular exertion are conducive to a speedy convalescence.

EXAMINATION FOR LIFE INSURANCE.*

I. A. McSwain, M.D., Paris, Tennessee.

The importance of this subject and the responsibilities connected with it, together with the fact that it has not been a usual one discussed at our meetings, would be a sufficient apology, if any was needed, for the presentation of this paper.

An idea may obtain entrance in the minds of some physicians that no special qualifications are necessary, and but little preparation is required for this work, when indeed the fact exists that in view of the financial interests involved in life insurance, and that the success or failure of the vast enterprise rests almost entirely with the medical examiners, it becomes a matter of great interest, and calls for much thought and careful study upon the part of medical men.

It is notable that the profession is not slow to recognize this, as several medical colleges have instituted special lectures on the subject; books have been written by able authors; instructions are sent out by medical directors of companies to local examiners, and no physician who accepts the office of medical examiner should long remain ignorant of his duties in the premises.

Most companies of any note pay a reasonable fee for examinations, and no member of a great profession, proverbial for its sense of honor, should take up a fee for which he had rendered no just equivalent. And indeed aside from the question of compensation, if we voluntarily accept an appointment or position, we should conscientiously discharge its requirements, or resign.

The object of a medical examination is to ascertain the true physical condition, personal and family history, hereditary or acquired predispositions, occupation and sanitary environments, and the mental and in some larger degree the moral status of the applicant.

In order that information on these lines may be had at the home office, blanks are furnished examiners on which to make the required reports; but while these blanks should be carefully filled in they should be considered as aids or conveniences, and in no sense should they take the place of careful study and inquiry on the part of the examiner.

To sit down and hurriedly run over the questions laid down on the blanks, and

*Read before the Tennessee State Medical Society April, 1895.

write applicant's answers, would in many instances amount to no examination at all. For this reason, the questions are easily understood by medical men, but many of them are without meaning to the average applicant unless they be explained.

Take one or two examples: "Have you ever had peritonitis, or any disease of the abdominal organs?" or, "Have you had stricture of the urethra, enlarged prostate, or disease of the genito-urinary organs?" In a blank before me, I find the following in a column of questions: "Apoplexy, diabetes, delirium tremens, epilepsy, fistula, insomnia, otitis, syphilis, varicose veins, &c."

A few men, who perhaps had given some attention to the study of medical terms, might answer such questions intelligently, but we must keep in mind a remarkable truth that however well posted a man may be in regard to the ordinary affairs of business or social life, he may not, and usually does not know anything about diseases, much less the names given them by the profession.

A physician is perhaps often excusable for using technicalities, for it frequently occurs that he does not desire the patient or friends to comprehend his meaning, or he might be in doubt as to his diagnosis and find it quite convenient to intrench himself by medical phraseology while he awaited further developments. But in examination for insurance, it must be the purpose to make ourselves understood; hence it would be better to ask the questions at once in such terms as we know the applicant can fully comprehend, or else explain their full significance before writing the answers. If we do not he is liable to give an unsatisfactory answer, from one of two reasons, either he does not wish to appear ignorant, or he will regard the questions as important relative to his acceptance, and will answer in the way most favorable to himself.

We must remember that in common practice the patient is anxious to explain everything connected with the disease or accident, and thus aid the physician in ascertaining the true condition; but the reverse is often true in the case before us. A person having once decided to apply for insurance, becomes anxious about it, and in no event does he wish to be rejected; hence the temptation to cover up his health record, or his family history if it be unfavorable, and it need not be expected that he will volunteer information that would be detrimental to his purpose.

Ingenuity and tact, together with a keen insight into human character, are in many instances needed by the examiner to enable him to elicit the facts and arrive at just conclusions.

We should never be content with such answers as "don't know," "female disease," "lingering illness," or, "old age." Such expressions are very confusing to the medical directors of a company.

For instance, "of what did your mother die?" "I do not know," or, "She died of female disease." Such answers would leave the company in great doubt on a vital point, that of family history.

So, if the desired information cannot be obtained from the applicant, search must be made elsewhere; the physician who attended her, or the nurse; if these cannot be found, some friend or acquaintance should be interviewed. I remember on one occasion to have gone nine miles for information relative to the family history of a man, who personally had the appearance of a good risk, but whose mother died in his infancy and he was unable to give satisfactory information relative to his maternal relations, some of whom it was reported had died of consumption. It cost me some time and trouble, but I secured for the company what has proved to be a first-class risk. All sources of information should be exhausted before we write unsatisfactory answers to vital questions.

Many persons know but little about their parents; very few indeed know anything about their grand parents, and such knowledge is sometimes difficult to secure, but we may frequently get the main facts from some old citizen who has known the family and their history through one or more generations.

I would like to state before leaving this part of the subject that an answer which would involve the rejection of the applicant should not be made without due consideration.

To illustrate, "Have you ever had vertigo?" This being explained to mean dizziness, or swimming in the head, he will probably answer, "Yes."

If this answer is so recorded and goes in unqualified, the company will naturally conclude that the "vertigo" is an indication of serious brain or aural trouble,

or apoplexy, and the applicant will be rejected, while perhaps the vertigo was caused by malaria, bilious disorder, loss of sleep, or some trifling ailment.

Very few persons have not at some time had palpitation, but we know that slight disorders of digestion or strong mental emotions may produce it, and if there be no disease of the heart, no irregularity of the pulse, no difficulty of breathing, only a little palpitation at some time, it should not be sufficient to reject the applicant.

In such cases as the above, we would be warranted in giving a negative answer.

"But," you say, "we should tell the truth." That is just it. But what is truth in such instances. It is that the vertigo or palpitation being wholly accounted for by the existence of slight ailments of other organs are mere functional disturbances, and a close examination showing a healthy brain and heart the symptoms referred to should be disregarded, for if answered affirmatively they would mislead the company, and the applicant would be rejected, not upon facts but upon a false conception of the applicant.

Examinations should always be made in private for obvious reasons, and when at all convenient, in the physician's office. When, however, the interest of the company demands it, we must not refuse to go to the house or place of business, for it is important that the examination be made with as little delay as possible after the application is made, otherwise, the party might change his mind, and thus the company be deprived of the business, and the family of the applicant remain unprotected by his failure to insure.

Examinations should never be made in a hurry. The company pays the physician for his work and he cannot do justice to either party in the transaction unless he takes time and acts deliberately.

If the applicant manifests restlessness and want of time, he should be informed that this is a business matter of importance and cannot be lightly treated.

No matter how hale and robust the applicant may appear, a careful physical examination should be made in every case. Previous to this, the applicant should be relieved as far as possible from embarrassment or morbid timidity. This may be done by some general conversation about the weather, business, or society. Then let him divest himself of his outer clothing, and shirt if it be stiff front, and place himself in an easy position. Proceed with the examination, having your own mind concentrated upon the object in view; but direct the patient's attention away from himself towards other objects. In short, it is desirable to arrive at the normal condition, free from all causes calculated to disturb or pervert the functions of respiration and circulation.

The abdominal organs, as well as the heart and lungs, should be submitted to physical examination, as should also the muscular and cutaneous systems.

Great caution must be exercised at this point—business habits, exercise, recreation, sleep, regularity in eating, the use of tobacco and other narcotics should be inquired into; but that which concerns us most is the drink habit. While it would be better if no man drank alcoholics as a beverage, yet moderate drinking of itself does not debar an applicant; so then if he drinks at all, we must find what he drinks and how much, when and where he drinks it, and with whom he drinks.

A farmer or laborer in the rural districts, industrious and frugal, regular in his habits of exercise, eating and sleeping, though he takes his "dram" with as religious punctuality as he attends church, and on certain great occasions becomes convivial and drinks to excess, might be a fair risk. But the man who loiters around saloons in idleness, though he may drink but little, yet is seen daily with the drinking and lawless element, engaging with them in their lives of debauchery and crime, should be promptly rejected because the baneful influence by which he is surrounded is sure to lead to profligacy and drunkenness. So that the line drawn by Dr. Anstie at one and one-half ounces of alcohol, or its equivalent, per diem, might be safe in rare instances—such as the farmer referred to, but certainly would be extremely dangerous if indulged in the ordinary drinking circles of towns and cities and under saloon influences. Therefore no definite quantity can be fixed without considering other factors involved in the habit.

No company ought to issue a policy of any sum whatever, unless the urine of the applicant has been thoroughly tested and found in a healthy condition.

I have repeatedly examined applicants, who in every other respect appeared to be

first-class risks and would be surprised to find the urine highly albuminous. This, if persistant, would necessitate the rejection of the applicant. The same might be said of other abnormal deposits.

It is not necessary in this paper to suggest methods for analyzing the urine, as it is presumed that every practitioner, whether he be medical examiner or not, has in his office the necessary apparatus, and certainly no one would attempt to perform the duties of medical examiner without first familiarizing himself with the essential part of the work.

We should also be assured that no deception is practiced, but that the specimen was passed by the applicant under examination.

There are other matters of importance connected with this subject that must be considered by the medical examiner, but can not be treated of in this paper within the time prescribed.

And while we exercise great prudence and care in every detail before recommending a risk for insurance, it must be remembered that a perfect human being, with a perfect health record, a family history absolutely free from disease or hereditary predisposition, one also who follows an occupation free from danger, and whose habits are above reproach, has never been found on earth since,

"Man's first disobedience and the fruit
Of that forbidden tree whose mortal taste
Brought death into the world, and all our woe,"

and our first parents receiving from Jehovah their marching orders, with much fear and trepidation took their final departure from the beautiful garden of Paradise.

So that due allowance must be made on account of the common frailties and infirmities incident to all the race. Otherwise insurance companies could have no existence, and the large benefits accruing by this wise provision would be lost to mankind.

Insurance companies desire business, and what they expect and require is such material as may reasonably be supposed will live out the ordinary expectancy,

Medical examiners having gained as nearly as possible all the facts, and having carefully reviewed and weighed them must make up their estimate of the case as a whole, and upon this basis, and with the golden rule before them recommend the acceptance or rejection of the risk.

In view of the essential qualifications of a medical examiner, his responsibilities, the necessity of thorough investigation, the demands made on his time by insurance companies, the delicate attitude he sustains both toward the company and the applicant, his fee in no case should be less than five dollars—in some instances more—and should always be paid by the company and from the home office.

THE USE AND ABUSE OF COCAINE IN NASAL DISEASES.*

S. W. SANFORD, M. D., UNION CITY, TENN.

Too often papers prepared for and read at these annual reunions are of such length, and deal so much in theorizing to the exclusion of practical, actual bed-side experience, that we are not benefitted by these meetings as we should be.

I will not take up much of the Society's time with this short article, yet if I succeed in impressing upon the members the alarming extent to which cocaine is used by the laity who are afflicted with some nasal trouble, I will have accomplished my purpose.

It is useless to consume your time in discussing the merits of this drug as a local anæsthetic, as that property is well known to you all, and as such it is indispensable to the oculist, dentist, and those of us who do much nose, throat and ear work. All operations in the nose, such as removing polypi, hypertrophies, exostoses, etc., are rendered painless by the use of a four, six, eight or ten per cent solution, thoroughly applied by a spray, or by saturating a pledget of absorbent cotton of suitable size and carefully applying it to the part to be operated on; or first spray and then apply the cotton satu-

*Read before the Tennessee State Medical Society, April, 1895.

rated with the solution—the latter mode of application being my preference.

I have found that in order to secure complete anæsthesia of the parts it is necessary to keep the solution in contact with it from ten to twenty minutes. My experience is that a ten per cent solution is sufficient, and many patients are so susceptible to the effects of this drug that a four or six per cent solution will be strong enough. I have found some patients who could not bear stronger than a two per cent solution. Although a twenty per cent solution is advised by such authority as Bosworth of New York, I would not use or advise a solution of such strength for two reasons; first, I have never found it necessary; and secondly, I regard the use of solutions of such strength dangerous; for it is a fact well known, that cocaine is very uncertain in its action, even upon the same patient.

The point, as I have stated, that I am most anxious to especially call attention to, is the alarming extent to which cocaine is being used by those who are sufferers from ordinary catarrhal troubles, particularly hypertrophic rhinitis. The fact that this drug so quickly astringes the mucous membrane, thereby giving immediate relief has been recognized and taken advantage of by unscrupulous manufacturers of patent medicines, and the daily papers are full of advertisements of Dr. So-and-So's never failing cure for catarrh, and every drug-store has it for sale. Now it is a fact that nine-tenths of these patent catarrh snuffs contain large quantities of cocaine, combined with menthol, bismuth, carbonate of magnesia and bi-carbonate of soda.

The sufferer from catarrh reads the flaming advertisement of Dr. Blank's wonderful and never failing catarrh snuff, and then goes to the nearest drug store, buys a box containing a powder similar to the above formula, pays an exorbitant price for it, with directions to "snuff a small quantity up each nostril several times a day or as often as needed to keep the nose and head clear." Now thus prepared to treat and cure his catarrh he goes on his way rejoicing and snuffing, and the relief he gets from the annoying and distressing symptoms is something wonderful to him, and he hastens to tell all of his friends who are thus afflicted, and those he fails to see, he sends word or writes to them, and still continues to rejoice and snuff and bless Dr. Blank for his wonderful discovery, and should he possess the title of Rev. So-and-So, D. D., the news of his miraculous cure and rescue from death will be heralded broad-cast over the country by means of an "unsolicited testimonial." By reason of his prominence as Rev. —— D. D., the more harm will be done; but lo! in a short time he finds that the more he snuffs the more he wants to snuff, and the more nervous he gets, and just here he finds that "Nature's sweet restorer" has taken wings. Then he goes to his physician, who may at the first consultation discover the cause of the trouble, but oftener he does not.

Now the patient has fallen a victim to one of the most, if not the most, seductive and dangerous of drugs, which has been called the greatest recent triumph of the Devil. If he were the only victim in that community it would not be so alarming but through his personal influence and the "unsolicited" testimonial the amount of harm done is simply appalling to contemplate.

This is what is being done daily in almost every community and by the most insidious means, and is wreaking sad havoc. In a majority of cases the patients are made victims innocently and unwittingly, and it is time for us as guardians of the public health to speak out with no uncertain sound, and invoke the aid of our legislators in exposing and crushing out this monster evil of the age the unrestricted manufacture and sale of patent medicines.

To more forcibly impress upon you the extent of this evil, I refer you to a paper read by Dr. George Wilkinson, of Omaha, Neb.—at the meeting of the American Medical Association, 1893. In this article Dr. Wilkinson gives a sketch from a study by personal contact with a colony of cocaine habitues in Omaha, caused from using one preparation advertised as a snuff and cure for catarrh, with the result of an assay of —as he calls it—"products of his Satanic Majesty." He states that the amount of cocaine used daily was often so much as forty to sixty grains.

This, gentlemen, seems to me to be a matter demanding most thoughtful and serious consideration.

TRANSLATIONS.

THE CHOREA OF PREGNANCY.

The chorea of pregnancy, according to Dufournier (*Le Bull. Mèd.* November 21, 1894) does not differ symptomatically from infantile chorea. The chorea of pregnancy occupies in the pathology of pregnancy a special place, in that it is not an accidental accompaniment of the pregnancy, but is provoked by the pregnancy itself. From an etiologic point of view, all of the causes which are noted as predisposing to infantile chorea, in large part are present in the chorea of pregnancy. The nervous system in these patients offers a special impressionability which may be hereditary or acquired after diverse affections. Chorea is transmissible by heredity. Lannois, Déjerine, Huet and Charcot are all in accord upon the importance of the role of heredity in the development of chorea. Another element of etiologic importance is the history of infantile chorea. When a young woman has been afflicted in childhood with a mild or severe chorea it is not rare for this to return in the first pregnancy. It appears most frequently in the first pregnancy, so that primiparity may be stated as a cause of the disease. But the rôle of primiparity must not be exaggerated, because primiparæ constitute the greatest number of pregnant women. Also chorea is most common among young women and these are most frequently primiparæ.

When a woman in her first pregnancy has presented the symptoms of chorea, it is frequent for her in successive pregnancies to show anew the disease, and in each recurrence in a more grave form. The opposite may also be seen, and a young woman who in her first pregnancy had been afflicted with chorea may not show any signs of it in subsequent pregnancies. It is a more complex matter to determine the part which rheumatism, chloro-anemia, hysteria, previous acute diseases, and in a general manner the various infections and auto-intoxications may have in the development of chorea. For a long time Sydenham's chorea was regarded as a rheumatic manifestation. It seems difficult to admit this interpretation in the case of the chorea of pregnancy, because in most of the cases the authors relate an absence of rheumatism in the antecedents of their patients. The analogy which exists between the modifications of puberty and the modifications of pregnancy from the point of view of the nervous system, may permit the adoption for the chorea of pregnancy the conception of Joffroy in regard to Sydenham's chorea, which he considers as a disease of evolution affecting the cerebro-spinal axis. W. A. N. D.

Influence of Odors upon the Voice.

It is well known to singers that perfumes influence the voice. The violet is regarded by artists as the flower which especially causes hoarseness. The rose on the contrary, is regarded as inoffensive. The subject is studied by M. Joal in a brochure recently published. He does not believe that the emanations of the violet prevent free vibration of the vocal cords, and thinks that if this flower has any injurious effect upon the voice the rose and other flowers must have the same action. There is, in fact, nothing fixed or regular in the influence exerted by the perfume of flowers. It is a matter of individual susceptibility. Some are affected by the lilac; others by the mimosa. Others, again, are in no manner affected by flowers, musk, amber, civet, or the various toilet preparations, but experience obstruction of the nose, hoarseness and oppression from the odors of oils, grasses, burnt horn, and the emanations from tanneries and breweries.

"It is very difficult," adds M. Joal, "to furnish an explanation of these peculiarities, and we must content ourselves by regarding them as examples of olfactive idiosyncrasy. It cannot be denied that odors may occasion various accidents and vocal troubles, especially in persons of nervous temperament and excessive sensibility. Six out of seven of his patients were decidedly neuropathic.— *La Médicine Modern.*

THE MEDICAL AND SURGICAL REPORTER

ISSUED EVERY SATURDAY

Address all communications to 109 and 111 Fifth Avenue, New York.

HAROLD H. KYNETT, A.M., M.D.
Editor.

RODERIC C. PENFIELD
Publisher.

Editorial Offices, 109 and 111 Fifth Avenue, New York.

Entered as second-class matter at Asbury Park, N. J.

TERMS:—Three Dollars a year in advance. Sent four months on trial for $1.00.

REMITTANCES should be made payable to the Publisher only, and should be made by Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We invite contributions of value to the profession, and if published originally in THE REPORTER such will be paid for at liberal rates, or a limited number of copies of THE REPORTER will be supplied, as the author may elect. Hereafter where reprints are desired writers are requested to make a note of that fact on the first page of the MS., but must order reprints directly from the publisher, who will supply the same at cost rates. Contributors should inclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, JUNE 29, 1895.

EDITORIAL.

DYING DECLARATIONS.

The following act is pending in the State Senate, having passed the House of Representatives of Pennsylvania:

AN ACT

Making dying declarations competent in prosecutions for criminal abortions and attempted abortions where the subject shall die in consequence of such unlawful acts.

Section 1. "*Be it enacted by the Senate and House of Representatives of the Commonwealth of Pennsylvania in General Assembly met, and it is hereby enacted by the authority of the same:*

"Section 1. That the ante-mortem statements of any woman who shall hereafter die in consequence of any criminal acts producing or intended to produce a miscarriage of such woman, as to the causes of her injuries shall be competent evidence on the trial of any person charged with the commission of such injuries with like effect and under like limitations as applying to dying declarations in prosecutions for felonious homicide.

"Provided, however, That before such statement shall be submitted to the jury as evidence, the Commonwealth shall by competent and satisfactory evidence prove that such woman was of sound mind at the time such ante-mortem statements were made. And provided, further, That no conviction shall be had upon the uncorroborated declaration of such woman.

"Section 2. All acts or parts of acts inconsistent herewith be and the same are hereby repealed."

If this was an act that created a few political offices thus increasing the leverage of the political power of our statesmen, it would receive their immediate attention. All good people, all with a high sense of what the justice and morals of a community should be, and would have the same copied into our law, will see the wisdom and justice of this act.

Yet all the virtue of this act should not

be destroyed by the one closing proviso—"That no conviction shall be had upon the uncorroborated declaration of such woman."

It should be remembered that it is only in very rare or exceptional cases that any but the wronged woman can testify as to the crime committed against her. The crimes to which she is most exposed are those of the darkness. She should be permitted to speak and speak freely under the rules of law which have centuries of endorsement.

ABSTRACTS.

TECHNIQUE OF MAKING URETHRAL INJECTIONS.

Guiard (*Annales des Maladies des Organes Genito-Urinaires*,), gives the results of his investigations concerning the urethra and its medication. The capacity of the uretera had been stated by Jarin and Leprevoct to be from five to eight grams, therefore it was held that a urethral syringe should not hold more than five or six grams, equal to about one and one-half drachms. Later it was shown that posterior urethritis, particularly late in the disease, was far more frequent than formerly supposed. The author by expermenting on the living subject found that the urethra would always hold eight to ten grams (two to two and one half fluid drachms), and more often twelve to fifteen grams, and sometimes sixteen to seventeen. As the patient could tell when the sphincter was forced, this was avoided. These deep injections are only called for when definite symptoms have already demonstrated that the posterior region of the urethra is already affected.

In order to administer these deep injections, the author uses a syringe of twenty grams (five drachms) capacity. When it is desired to overcome the sphincter, gentle pressure is made when the liquid will enter. In an experience of ten years he has never had any accidents, and only encountered one case in which the sphincter would not relax. It is better to give the injections when the patient is lying down than when he is standing up. The requirments of an effective injection is that it shall reach the diseased parts. To do this a syringe of twenty grams (five fluid drachms) capacity should be used, and the injection of its entire contents, if carefully done, is easy and causes no inconvenience. —*Univer. Med. Mag.*

THE CAUSE AND PREVENTION OF NEURALGIA IN AMPUTATION STUMPS.

Witzel (Centralbl. f. Chir.), holds that neuralgia after amputation is not caused, as is generally supposed, by the formation of neuromata at the ends of the divided nerves. He states that if such were the case it would be necessary to lay aside the amputating knife. The neuralgic pains, he believes, are due to adhesion of the neuromatous swelling to the end of a bone. In order that its functions may be properly performed a nerve should move freely in its sheath. The structural elements which serve the special functions of a nerve are during life extremely delicate and almost fluid. The ordinary movements, therefore, of an adjacent joint would interfere with the structure and functions of the nerves of a limb if these nerves had no longer free range of movement in the direction of their long axes. In two cases of neuralgia after amputation in which Witzel had opportunities of dissecting the

stumps he found thick neuromatous swellings at the ends of the divided nerves. which were bound down by tough cicatricial tissue to the ends of the bones. It is evident that during movements of the stump at the nearest joint the fixed nerves must be stretched, those on the flexion side during extension and those on the extention side during flexion. In neuralgia caused by confinement of a nerve in a mass of callus the pain, it is held, is due to the prevention of the nerve's movement and not to its compression. As a preventive treatment Witzel recommends that in every amputation as much attention should be paid to the nerves as to the large arteries, and that the former should be pulled away from the flaps and divided high up. Attention should be particularly directed to this precaution in cases of amputation at the ankle and shoulder.—Brit. Med. Jour.

THE CLINICAL USES OF APOMORPHINE.

In an extended article, J. Boyer and L. Guinard (*Bull. Génér. de Thérapeutique*) write of the physiological action and clinical uses of apomorphine. The authors state that the drug produces two kinds of physiological phenomena, one being characterized by *excitation*, in which spasms, trismus, convulsions, agitation, vertigo, and hyperæsthesia are observed; the other, by *depression*, in which there occur syncope, collapse, hypothermia, general weakness, muscular paralysis, weakness and arrest of respiration, cardiac enfeeblement, and anæsthesia. These various phenomena are the result of the actions of two different kinds of drugs. The writers believe that the crystalline form of apomorphine causes exciting and convulsive phenomena, while the amorphous salts of the drug produce chiefly symptoms of stupor and paralysis. To obviate the production of diverse phenomena, and in order to obtain in the adult a simple and pure emetic effect, the white *crystalline hydrochlorate of apomorphine* should be employed in doses of 3 to 5 milligrammes ($\frac{1}{20}$ to $\frac{1}{12}$ grain). The authors believe that, judging from the results of the principal researches so far published, and which they review in a careful and thorough manner, apomorphine is a medicament of real value. Its efficacy and the superiority of its action over other emetics have been established. The easy method of its administration by subcutaneous injections and the rapidity of its action make it an excellent therapeutic agent. If employed in a pure form, apomorphine will not cause serious after-effects.—*Therapeutic Gazette.*

HOT SALINE BATHS IN INFANTILE PARALYSIS.

In the chronic stage of infantile paralysis, the mother should be instructed to bathe the affected parts daily with a hot solution of common salt. The solution should be of the strength of three or four ounces of salt to a quart of water and the application should be as hot as can be borne and should be followed by vigorous rubbing of the affected parts with oil. The mother should also be instructed to flex all the joints completely, taking care to antagonize any tendency to equinus, or equino-valgus, or-varus, which may occur. The writer recently operated upon a case in which the most extreme degree of equinus possible, had resulted from neglect of this precaution. Both feet were affected. In one foot the equinus was complicated with varus, and in the other with valgus. These cases are often neglected, to the great detriment of the patient. Applications of electricity, systematic massage, and skillfully directed gymnastics are of great value in these cases, and should be employed as soon as lesion is discovered, or at least as soon as the acute symptoms have disappeared. In some cases orthopædic apparatus is necessary to prevent serious deformity. Great results can often be accomplished in these cases; even the most unpromising symptoms may sometimes be made to yield surprising results by persevering treatment.—*Ed. Mod. Med.*

THE LIBRARY TABLE.

TWENTIETH CENTURY PRACTICE.—An International Encyclopedia of Modern Medical Science, by leading authorities of Europe and America. Edited by Thos. L. Stedman, M.D., New York City. In twenty volumes. Volume I, "Diseases of the Uroporetic System;" Volume II, "Nutritive Disorders." New York: Wm. Wood & Company. 1895.

Wm. Wood & Co., the well-known medical publishers of New York, have conceived and are carrying into execution one of the most daring ventures known in the history of medical publications. A colossal work of twenty large octavo volumes, presenting in some fifteen thousand pages all that is pertinent to the practice of modern medicine, as set forth by upwards of one hundred of the leaders in medical thought, men, who, without exception, are of international reputation.

During the past two decades numerous strides have been made toward placing the art of medicine upon a scientific basis, and it is the purpose of the present publication to place before the medical world, the results of the profound study which has done so much to revolutionize our notions as to the prevention and cure of disease. It is probably safe to say that never before was such an aggregation of medical masters secured as in the production of this enterprise.

The initial volume treats of "The Uroporetic System" and includes elaborate discussions of the diseases of the kidneys, ureters, bladder, prostrate, male and female urethra and urine.

The contributors are Francis Delafield, Howard A. Kelly and G. Frank Lydston of America, and Reginald Harrison and E. Harry Fenwick of London.

The work opens with a masterly monograph on "Diseases of the Kidneys," by Francis Delafield of New York, and the section by Reginald Harrison of London, upon "Diseases of the Ureters and Surgical Affections of the Kidneys," reflects great credit upon the writer.

Special attention is directed to the chapter by Howard A. Kelly of Baltimore, on "Diseases of the Female Bladder and Ureters," which is full of originality and marks a great advance in a heretofore much neglected branch of gynecology.——

The second volume of this work comes to us as a monument of much instructive, as well as interesting reading, and its builders are Dujardin-Beaumetz, Sir Dyce Duckworth, Archibald Garrod, Henry M. Lyman, Thos. J. Maclagan, Carl von Noorden and Max J. Oertel—an array of talented writers, quite sufficient to insure the worthiness of the book.

The work opens with an interesting essay on "Addison's Disease and Other Diseases of the Adrenal Bodies," by Sir Dyce Duckworth, of London. He admits that little new light has been thrown upon the nature of these diseases, or on the functions of the supra-renal capsules since Dr. Thos. Addison of Guy's Hospital first called attention to the subject in 1855.

"Diabetes Mellitics" is disposed of in a fluent manner by Prof. von Noorden of Frankfort, and he offers some suggestive proof as to the possibility of certain exceptional cases of this affection being contagious; an idea, however, which is strongly controverted by other eminent observers. It is interesting to note that although this article comes from the pen of a German physiologist, some sixty pages are devoted to the consideration of treatment.

Prof. Max J. Oertel completes the volume by a treatise on "Obesity." This monograph bears with it special weight, since the writer may be regarded as the inventor of, perhaps, the most successful method of treating this inconvenient ailment.

In conclusion it may be said that this second volume, as a whole, quite maintains the high standard accorded its predecessor.

W. H. P.

TRANSACTIONS OF THE ANTISEPTIC CLUB. Reported by Albert Abrams. Illustrated. New York: E. B. Treat. 1895. Price, $1.75.

Intervals come in every practitioner's life when a little light reading affords a relaxation to the mental strain incident to every busy life. The present volume contains its share of humor and manifests a considerable originality of wit on the part of its author.

SUGGESTIVE THERAPEUTICS IN PSYCHOPATHIA SEXUALIS; with Especial Reference to Contrary Sexual Instinct. By Dr. A. Von Schrenck-Notzing (Munich, Germany). Authorized translation from the German by Charles Gilbert Chaddock, M.D., Professor of Diseases of the Nervous System, Marion-Sims College of Medicine, St. Louis; member of the American Medico-Psychological Association; Attending Neurologist to the Rebekah Hospital, St. Louis, Mo., etc., etc. One volume, royal octavo, 325 pages. Extra cloth, $3.50 net; sheep, $3.50 net. Sold only by subscription to the medical profession exclusively. Philadelphia: The F. A. Davis Co., Publishers, 1914 and 1916 Cherry street.

Aside from the interesting reading which this book affords, a new field of treatment is opened up, applicable to a class of cases which often prove most intractable to cure. The author recounts in detail some seventy cases of sexual perversions treated by hypnotic suggestion, some ineffectually, but the majority either cured or manifestly improved.

This work, while of benefit to the intelligent physician, would be a great source of harm were it to reach the hands of the laity—a calamity which the author seeks to avoid by preserving a strictly technical style.

A MANUAL OF THE MODERN THEORY AND TECHNIQUE OF SURGICAL ASEASIS. By Carl Beck, M. D., Visiting Surgeon to St. Marks' Hospital and the German Polliklinik of New York City, etc., with 65 illustrations in the text and twelve full page plates. Philadelphia: W. B. Saunder's, 925 Walnut St. 1895. Price, $1.25.

Owing to our increasing knowledge of the subject of bacteriology, and the consequent advancement in surgical technique, it is quite impossible for the larger text books on surgery to keep abreast of the times. In the manual before us we have a thoroughly up to date presentation of the subject of surgical asepsis and the practical methods of securing it. In addition to the interesting chapter on the influence of microbes, the author details the method of sterilizing instruments and dressings; of treating aseptic and infected wounds; of preparing an operating room in a private house as well as in a hospital (etc).

A chapter on Anæsthesia is a feature. This is a valuable addition to the book and should receive the careful notice of every physician. In embarrassed reputation the author describes the method usually adopted, namely to force the jaws apart with an instrument and draw out the tongue with forceps, and push the angle of the jaw forward. The critic believes this to be a needless waste of time and energy. If the head be lowered and the point of the chin be firmly drawn back so as to put the muscles, joining the chin, the hyoid bone and the sternum on the stretch, the tongue which is attached to the hyoid bone must necessarily be raised up and the glottis opened—and if the nose is not obstructed air will rush in.

The book is well illustrated, the print excellent and altogether it does credit to the well known publisher. W. E. P.

SURGICAL PATHOLOGY AND THERAPEUTICS, by John Collins Warren, M.D., Professor of Surgery in Harvard University; Surgeon to the Massachusetts General Hospital. For sale by subscription only. Cloth, $6.00; one-half morroco, $7.00. W. B. Saunders, publisher.

This work covers the subject well, handling it in an entertaining style, and leaving the reader with a clearer idea of the pathological conditions in a given surgical case than he could get from a book in which operative technique was given on the same page with the description of the disorder. The book is intended particularly for those who have more or less practical acquaintance with surgery, and who are anxious to study it further in a more purely scientific way.

Beginning with a description of bacteria as the cause of various disorders, lencomaines and ptomaines are defined, and a general outline given of the methods for their study now followed in laboratories, but for minute details the reader is referred to books on bacteriology.

Inflammation of various kinds is now taken up and the supposed causes given; then surgical diseases, tuberculosis, actinomycosis, gangrene and others, and their clinical appearances described.

The differences in appearance, structure, and progress, between different varieties or benign and malignant growths, and the different treatments to be adopted follow, and finally a chapter on aseptic and antiseptic surgery.

Very many fine illustrations, the majority of which are collected, present a vivid description of the subjects written about.

PERISCOPE.

IN CHARGE OF WM. E. PARKE, A.M., M.D.

MEDICINE.

Chest Pains.

These may be due to:

1. Intercostal neuralgia; tenderness at points only.

For neuralgia strap the chest and give arsenic, with an occasional mercurial purge. Quinine acts best after mercury.

1. Rheumatism of the fascia, the whole region being tender.

Chest rheumatism is connected with beer-drinking. The salicylates are useless; alkalies of doubtful utility. The best remedy is water drunk in enormous quantities.

3. Neuritis; circumscribed linear tenderness.
4. Acute pleurisy; chill, fever, friction sound.
5. Dry pleurisy: very common, relieved so surely by adhesive straps that this relief confirms the diagnosis.
6. Neuroma.
7. Aneurism; may not cause pain, even if large.
7. Cancer.
9. Ataxia.
10. Spinal disease.
11. Bronchitic pain; calls for strapping and opium.
12. Myalgia; relieved by straps.
13. Mitral disease; rarely painful.
14. Aortic disease; generally painful.

Premature Births.

M. Villemin (*Universal Medical Journal*) reported before the Societe Obstetricale et Gynecologique the case of a two-year-old child, born in the sixth month of pregnancy. That the child had not had six months of intrauterine life he could vouch, the statement being borne out by the last menstrual period of the mother, the date of the first fetal movements, the child's weight, which was thirty and a half ounces, and its appearance.

Budin had had this infant under observation from the beginning and corroborated Villemin's statements He had examined infants of six or seven months that had cried and lived a few days and had found the alveolar cavities filled with epithelial cells, the lung sinking when placed in a vessel of water.

Charpentier reported a case of premature birth in his practice, the child being not more than 6½ months and weighing thirty-three and one-third ounces. So sure was he that it would not live that he placed it in a basin while he was attending to the mother. After the mother was attended to, the child being still alive, he wrapped it in cotton, and was surprised next day to find it alive. It was then placed in a small well-heated room and fed with a spoon on human milk; on the twelfth day it could take the breast, and since it has thrived and grown.

Gastro-Intestinal Disorders and Female Affections.

Theilhaber cites forty-five cases (*Boston Med. and Surg. Journ.*) of women suffering from stomach disorders, twenty-five with nervous dyspepsia, twelve with stomach atony, two with stomach catarrh, two with chronic intestinal catarrh, and four with other affections. Gynæcological examination revealed absence of any abnormalicy in four cases; in nineteen catarrhal endometritis, with more or less thickening of the parenchyma of the uterus, three of oophoritis, two of parametritis, one of old puerperal parametritis, one of retroversion of the antefluxed uterus, and one of small ovarian tumor. As to the connection between the gynæcological troubles and the stomach and bowel affections, Theilhaber divides the cases into three groups. The first embraces those cases in which the gynæcological condition is only a chance occurrence. In the second group belong those cases in which the gynæcological disturbances are caused by the gastro-intestinal affection. Theilhaber mentions here especially cases in which metrorrhagia and dysmenorrhœa are caused by constipation. In the third group the uterine condition is the cause of the stomach trouble. Six of the patients with nervous dyspepsia suffered from retroflexion; in four of these the dyspepsia was cured by the reposition of the uterus, in two not. Nervous dyspepsia and hœmorrhagic endometritis existed in three cases. In two the digestive difficulties which had existed for years disappeared after curetting; one patient withdrew herself from treatment. Of eleven cases of nervous dyspepsia and catarrhal endometritis local uterine treatment had prompt effect in eight. Four cases of stomach atony which were associated with various local conditions were cured coincidently with the cure of the uterine conditions. Theilhaber concludes from his observation that in all cases of nervous dyspepsia, atony of the bowels, or of the stomach, hyperacidity, want of acidity for a long time where rational medicinal treatment has not been successful, thorough gynæcological examination should be made especially when the patients complain of menstrual irregularities or of leucorrhœa. Still though gynæcological treatment is important, it is necessary that stomach treatment should also be carried out.

Intramural Abscess Cavity Filled With Gas and Purulent Material.

(*American Journal of Obstetrics and Diseases of Women and Children.*) By A. F. Jonas, M.D.

Labor in which the right arm presented, necessitating version, was followed a month later by enormous enlargement of the abdomen, the circumference measuring forty-eight inches. On examination, a large mass was found, attempts to move which caused simultaneous movements of the cervix and the supposed fundus. A cystoma with infectious contents was diagnosed and an operation performed. A trocar was introduced into the tumor, and on withdrawal a large quantity of fetid gas rushed out, which reduced the tumor nearly one-half, and was followed by very thick purulent material which contained broken shreds and sloughing tissue. The fundus uteri, ovaries, and tubes were found forced low down in the pelvis and free posteriorly, but anteriorly the uterus was attached by its entire surface to the wall of the cystoma, which was located between the bladder and the uterus. There was no connection with the uterine cavity.

The origin of the abscess was in the anterior uterine wall, and it gradually separated the muscular layers as the quantity of pus increased. Suppurative processes in muscular structures usually produce liquefaction unless a capsule such as would surround a neoplasm is present. A small fibroid was found in the posterior wall, and, since fibromata are frequently multiple, it is not improbable that one existed encapsulated in the anterior wall. An existing intramural fibroid subjected to long continued pressure, such as would occur in pregnancy, becomes more or less bruised, and is in excellent condition for microbic infection, development of suppuration, and distention of the cavity with gas, the product of microbic action. So large a quantity as was found in this case is extremely rare.

Nuclein in Therapy.

Dr. F. W. Garber cites thirteen cases benefitted by the use of Vaughan's nuclein. Of these (*Therap. Gaz.*) ten were of tuberculosis, one of neurasthenia, one of follicular tonsilitis, and one of troublesome sinus with phlegmonous cellulitis induced by a sloughing tendon leading from the second finger high into the palm of the hand. Dr. Garber concludes nuclein is of value in incipient tuberculosis. Whether positively curative he is not yet in position to say, but by its early use it is possible to give patients longer lease of life and very much more comfort. If the patient be in position to take advantage of favorable climatic conditions, he has great faith in the complete restoration to health by the use of nuclein of a large number of persons now dying under other treatment.

Tying the Funis to the Maternal Thigh.

Dr. W. M. Guice of Louisiana reported a case of labor (*Med. Brief*) in which he found the funis tied to the maternal thigh to prevent it escaping into the uterine cavity. Dr. White of Riley, Kansas, reports the case of a II-para. He found the child born and the cord tied to the mother's thigh. He cut it and removed the placenta while a neighbor woman bathed the child. She had tied the cord to the mother's leg to prevent it from going back. This is an odd piece of obstetric folklore found among many races. In both instances the women were Americans.

In the Department for Diseases of the Chest, Dr. Mays prescribes sodium salicylate in pleurisy. The pleural cavity bears a marked structural analogy to the synovial sacs, and is as liable to rheumatic attack as they are; and these cases are greatly benefitted by the agent mentioned. Unless clearly due to other causes, pleuritic affections ought to be tested by an anti-rheumatic drug. Even in cases of serous effusion, or of empyema, either before or after the fluid has been drained off, sodium salicylate is of great value. It is given in five or ten-grain doses, four times a day.—*Polyclinic.*

A French doctor, according to the Cincinnati *Medical Journal*, has devised a vibrating helmet, constructed of strips of steel, and the motive power is a small electric motor. Its inventor uses it in case of nervous headache. The sensation, which is described as not unpleasant, produces drowsiness, the patient falls to sleep under its influence, and awakes to finds that the pain has ceased.

In the Treatment of Pleural Effusion

Segalea (*La Medecine Moderne*) has employed with success topical applications of guaiacol in the following formula:

Guaiacol	m xxxvi.
Glycerin }	ää ℥ss.
Tincture of iodin }	

M.

The applications are made by means of a brush to the entire posterior aspect of the chest, which is then covered with cotton and an impermeable dressing and a bandage.

In a case of anasarca, with anuria, in the sequence of scariatina, in which other measures had failed, applications of the following combinations were soon followed by relief:

Guaiacol	m xvi.
Glycerin	℥ss.

M.

—*Medical News.*

The Contagion of Mumps.

Le Courrier Medical gives some interesting information concerning mumps. The incubation period varies from eighteen to twenty-two days. It is especially contagious during this period, but is also contagious for some time after cure. The exact length of time has not yet been determined. The parotid and testicular fluids and also the blood appear to contain a certain pathogenic organism, but as yet this point is unsettled. Hitherto the results of inoculation with this special microbe have been negative. Frequently the disease begins with tumefaction of the submaxillary glands and a severe angina. Sometimes in metastatic orchitis the swelling begins with an epididymitis.—*Mod. Med.*

Aphasia Occurring During Convalescence from Typhoid Fever.

Dr. S. B. Ward reports a case (*Albany Medical Annals*). W. S., a boy 12 years of age, suffering with typhoid fever. I saw him on the morning of the 4th, and found that great improvement had occurred during the preceding twenty-four hours. He was exceedingly weak, having had a severe attack with a pneumonic complication, during the preceding four or five days; but the lung was clearing up; the temperature was below 101° F.; he was taking nourishment well, and there seemed to be a fair chance of his recovery. He was somewhat deaf, but gave clear evidence of hearing when spoken to in a raised voice. I noticed that he did not answer the question I asked him, but the nurse attributed this to great weakness, and as no importance attached to his answer, no further effort was made to question him. On November 9th his father wrote me that he was better; his strength improving daily, and his hearing much better.

This case is, in my experience, so unusual that it seems worth while to put it on record. Embolism during typhoid, or during the convalescence from typhoid, are by no means rare and the left anterior cerebral artery is probably as likely to be affected in this disease as in any other; but in the large majority of cases of aphasia due to embolism paralysis is present in some degree in some locality, while in this case it was entirely absent. Besides the trouble passed away so rapidly as to preclude the probability of its being due to embolism.

...pically, as a Prophylactic against Diphtheria.

...olis-Cohn reports favorable re... in applying guaiacol to the thro... / healthy children who have been exposed to diphtheria. He uses Merck's preparation, and applies it either full strength or a fifty per cent. solution with glycerine or olive oil. It should be well rubbed into the tonsils and pharynx once daily. In case the throat is already affected, it should be applied twice a day.—*Philadelphia Polyclinic.*

The Treatment of Obesity.

Extensive trials have been made in France with thyroid extract in the treatment of obesity, and cases are recorded in which it would seem that very marked results followed the employment of this remedy, either by subcutaneous injection or by the mouth. The dose usually given amounted to about 15 1-2 minims of the thyroid juice daily, and in three months, in one instance, the patient's weight fell nearly 40 pounds. As soon as the treatment was discontinued the loss of flesh also ceased, and when the thyroid extract was resumed a daily loss of between three and four ounces again occurred. In other cases, however, the treatment was followed by no marked results, and the conclusion therefore, is obvious—either that the cause of the obesity must have been different, or that the thyroid extract may have been impure. On the other hand, it has been conclusively proved, in this country, that the use of the remedy may be followed by somewhat dangerous nerve symptoms, and that, in fact, the thyroid extract, powerful as it has proved to be in the treatment of various diseases hitherto considered to be difficult of cure, may be attended by results of an alarming character; and there is, therefore, reason to feel that firms which prepare this remedy would be well advised to dispense it only under medical direction.—*Med. Times and Register.*

SURGERY.

Cases Simulating Meningitis Without Corresponding Anatomical Lesions ("Pseudomoningitis").

Krannhals (*Deutsches Archiv fur klinische Medicin*) reports seven cases in which the symptoms were almost exclusively nervous, and in which the diagnosis of meningitis was made, although some of the more characteristic symptoms were wanting. One case ended in recovery; the termination of another could not be determined; five died. The findings at the post-mortem examination did not confirm the diagnosis, there being no exudate, no inflammatory turbidity, nothing but hyperemia and edema of the pia, and a varying number of hemorrhages in the same membrane. The microscopical examination of two cases confirmed the pre-eminent hemorrhagic character of the affection, and the absence of any real inflammatory changes, if one does not regard as such the edema of the pia, which in reality had the character of an edema due to congestion rather than inflammation. The brain itself showed no inflammatory changes; on the contrary, here and there, in the superficial layers of the cortex, there was a retrograde metamorphosis, a beginning necrosis due to a disturbance of the circulation brought about by the numerous hemorrhages in the pia. Bacteriological examination of the meningeal serum of three cases proved negative. Krannhals seeks to explain an intimate relationship between influenza and these cases of "pseudomeningitis," occurring as they did during the spring of 1890, following the influenza epidemic. He believes that the symptoms of the cases of "pseudomeningitis," due to some infectious process, and of acute meningitis in general, depend especially upon the action upon the central nervous system of certain toxines, and secondarily upon the anatomical lesions present.

NEWS AND MISCELLANY.

Reduced Rates to Baltimore.

The B & O. R. R. Co. will sell excursion tickets to Baltimore from all points on its lines east of Ohio River at one fare for the round trip. Tickets will be sold July 16th and 17th, valid for return passage until August 5th. For time of trains and full details, call or write nearest B. & O. Agent.

The rate from Philadelphia will be $2.80 and correspondingly low rates from other points.—3t.

Summer Vacation Tours.

The Baltimore and Ohio R. R. Co. now has on sale at all its offices east of the Ohio River a full line of tourist excursion tickets to all the lake, mountain and seashore resorts in the Eastern and Northern States and in Canada. These tickets are valid for return journey until October 31. Before deciding upon your summer outing it would be well to consult the B. & O. Book of "Routes and Rates for Summer Tours." All B. & O. Ticket Agents at principal points have them, and they will be sent post paid upon receipt of ten cents by Chas. O. Scull, Gen'l Passenger Agent, B. & O. R. R., Baltimore, Md.—2t.

Low Rates to Denver.

The B. & O. R. R. Co. will place on sale at all ticket offices on its lines east of the Ohio River round-trip tickets to Denver, Colorado Springs, Manitou and Pueblo, for all trains of July 2, 3, 4, 5, and valid from starting point on day of sale and good returning from Colorado points July 12 to 15 inclusive. The rate from Philadelphia will be $44.75, and correspondingly low rates when from other stations. Tickets will be good via St. Louis or Chicago.—3t.
